WILSON, J. T., Sherman, Texas.
WORTHINGTON, R. H., M. D., Denver, Col.
WYLIE, W. GILL, M. D., New York City.

INDEX.

Abdomen, treatment of penetrating wounds of, 552.
Abdominal nephrectomy, 10.
Abdominal section, conditions after parturition requiring, 86; for acute intestinal obstruction, 189.
Abdominal tumors, 930.
Abdominal uterine tumor, 373; surgery, ten commandments of, 238.
Abortion at five weeks, 334.
Abscess, hepatic, rare case, 270; ischio-rectal, 8.
Acetanilide, 729.
Acetone, test for in expired air, 156.
Acne varioliformis, histology of, 143.
"A cold in the head," 199.
Aconitine, in trigeminal neuralgia, 581; test for crystallized, 197.
Actinomycosis, 503.
Adenitis, chronic inguinal, 250; tubercular, 81, 1016.
"A diagnosis," 558.
Advertising doctor, 478.
"Advice to a young physician," 679.
Ague, parasite in quartan, 118.
Aid to palpation, 125.
Air passages, foreign bodies in, 77.
"A law case," 545.
Albuminaturia, 1018.
Albumen tests, 197, 838, 878.
Albuminuria, and molar pregnancy, 432; in diabetes, 510; in persons apparently healthy, in relation to life insurance, 310; normal, 184; transient and dietetic, 752.
Alcohol, physiological effects of, 797; how to detect in ether, 277; in patent medicines, 559.
Alcoholic beverages, adulteration of, 638.
Alexia, subcortical, 751.
Alimentation and artificial foods, 610.
Alkalies in universal pruritis, 828.
Alkaloid from tubercle bacilli, 80.
Alkaloids, ammonium selenide as a reagent for, 759.
Alloy imitating gold, 997.
Aloin, action of, 267.
Amblyopia, treatment of toxic, 346, 463.
Amenorrhœa, complete in a fertile woman, 834; treated by Swedish movements, 514.
American Electropathic Association, 199.
American Medical Association, Membership, 397.
American Public Health Association, 200, 597.
American Society of Microscopists, 38.
American Surgical Association, 358.
Ammonium selenide as a reagent for alkaloids, 759.
Amniotic fluid, composition, 472.
Amputation of fore-arm, 441.
Anæmia, in children, nucleated red-corpuscles in, 34; infantile splenic, 43; intravenous injections of soda in, 631; pernicious, 84.
Anæsthesia, local, a new method, 747.
Anæsthetic, choice of in obstetric practice, 575; in obstetrical practice, 541; chloride of methyl as a local, 548; problem, 339.
Analgesic action of antipyretics, 344.
Anal reflex, 225, 585.
Anastomosis, intestinal, modified suture, 28.
Ancestors, appetite of, 840.
Anders, Jas. M., M. D.—Asthma, 561; chronic nephritis, 41; influenza, 841.
Anders, Howard S., M. D.—Necrosis of the femur, 773.
Angina, acute, treatment of, 307; Ludovici, case, 110.
Aniline colors as antiseptics, 147.
Aniline injections in malignant neoplasms, 228.
Animal, parasites, 503; remedies, fanciful, 476.
Animals, experiments on, 599.
"An ounce of prevention," 237.
Anthrax, treatment of, 347.
Anticylic acid: a new antipyretic, 905.
Anticholeroic inoculations, 390.
Antidiaphoretics, 864.
Antifebrin and antipyrin in polyuria, 464.
Antifebrin, in broken doses, 909; in cerebro-spinal meningitis, 546.
Antigalactagogue, antipyrin as an, 993.
Antipyresis by drinking large quantities of cold water, 20.
Antipyretics, analgesic action of, 344; in children, 676.
Antipyrin, as a local application to respiratory tract, 690; and antifebrin in polyuria, 464; elimination of, 630; iodide of, 476; in chorea, 787; incompatibles, 154; in pleuritic effusions, 106; in tetanus, 381; galactagogue, 993.
Antisepsis, what it has done, 597.
Antiseptic, and aseptic surgery, 619; oil of peppermint as an, 864.
Antiseptics, action on peritoneum, 511; aniline colors as, 157; in the treatment of typhoid fever, 103.
Antiseptic, invagination, permanent, 188; treatment of wounds, 166.
Anti-tobacco movement in France, 198.
Anti-vaccinationists, a Russian pill for, 598.
"A Parisian Dinner," 520.
Aphonia cured by hypnotism, 424.
Aphorism in medical emergencies, 268.
Apostoli's method, 471.
Apothecary and prescription, 786.
Appendicitis, 161, 445, 808, 963; a case of four attacks in one year, 427; the surgeon in relation to, 859.
Appetite of our ancestors, 840.
Apyorin, 476.

Are we too clean, 153.
Aristol, in diseases of ear and nose, 266; in diseases of the eye, 24; in phthisis, 787; in tuberculosis, 749; value of, 310.
Army medical Board, 278.
Arsenical neuritis, 25,
Arsenite of copper, 19; priority in use of, 305.
Asepsis, dental, 718.
Aseptic and antiseptic surgery, 619.
Ashhurst, John, M. D.—Appendicitis, 161.
Ashton, William E., M. D.—Relation of laceration of the cervix to malignant disease and its treatment, 328.
A singular case, 217.
Asparagus, action on kidney, 750; pharmacology of, 269.
Asthma, 561; fumes of bromohydrate of ammonia in, 508; of children, 756; powder, 622; relation to other diseases, 712; treatment, 1015.
Ataxia, Fredericks, 325.
Atresia hymenalis, acquired, 833.
Atresia of the rectum, artificial anus, 755.
Atrophic elongation, 699.
Atrophy of the liver, acute, 790.
Atrophy in joint disease, 699.
Atropine and duboisine, hypnotic action, 181.
Atropine in emesis, 548; in disease of the eye, 568; in heart diseases, 945.
Aulde, John—letter, 19.
Aural vertigo, points in pathogenesis of, 185.
A worthy project, 264.

Bacilli, of leprosy and tuberculosis, new method of staining, 598; Kochii, tragic and lamentable death, 159; of leprosy, cultivation of in serum, 480; pyocyaneus, action of products of, 791; tubercle, chemistry and toxicology, 155; tubercule, passage from mouth to fœtus, 436; tubercle, identification and staining, 35.
Backache as a symptom of local disorder, 915.
Baer, B. F.—Dysmenorrhœa, 681.
Baldness, cause and cure of, 707.
Baldy, J. M., M. D.—Inversion of the uterus, 123.
Bananas in chronic bronchitis, 383.
Bassette, M. Imogene.—Facial paralysis, 485.
Baths in typhoid fever, 462; physiological effects of, 220.
Beer-drinking and heart disease, 800.
Belgian Acad. of Med., 237.
Belladonna plaster, poisoning by, 72.
Benedict, A. ,L., M. D.—Right occipito-posterior delivery, 443.
Benjamin, Dowling, M. D.—Ovariotomy followed by ventral hernia, 1006.
Benzole in whooping-cough, 676.
Benzoyl-eugenol, 719.
Benzrugenol, 719.
Beverages, adulteration of alcoholic, 638.
Bile pigment in fæces, detection by Gmelin's test, 878.
Billings, Josh, on doctors, 879.
Bladder, motor nerves of, 520.
Bleeding, therapeutics and physiology, 309.
Blood during pregnancy and puerperium, 472.
Blood, germicidal power of, 710.
Bloom, Homer C., M. D.—Chronic endometritis, 284.
Blume, F., M. D.—Vomiting of pregnancy, 289.
Boil, to abort, 237.

Book Reviews:
Ball, M. V., M. D.—Bacteriology, 826.
Bartholow, Roberts, M. D.—Hypodermatic Medication, 903.
Beard, Geo. M., M. D.—Sexual Neurasthenia, 343.
Blakiston & Co.—Self-examination for Medical Students, 706.
Chamneys, Francis Henry, M. D.—Painful Menstruation, 786.
Gunn, Mrs.—Memorial Sketches of Moses Gunn, 106.
Halliburton, W. D., M. D.—Chemical Physiology, 306.
Hamilton, John B., M. D.—Tumors, 746.
Hare, Hobart Armory, M. D.—Fever: its pathology and treatment, 69; Essentials of Physiology, 628.
Hewitt, Graily, M. D.—Severe Vomiting during Pregnancy, 137.
Hutchinson, Proctor S., M. D.—Diseases of the Nose, Throat, Pharnyx and Larynx, 667.
Leonard, Henrie, A. M., M. D.—Materia Medica and Therapeutics, 19; Pocket Anatomist, 706.
Lippincott & Co.—International Clinics, 544.
Long, Eli H., M. D.—Tables for Doctor and Druggist, 577.
Martin and Hare—Surgical Treatment of Wounds and Obstructions of the Intestines, 667.
Mays, Thos. J., M. D.—Pulmonary Consumption, 628.
Mills, Chas. K., M. D.—Philadelphia Hospital Reports, 178.
Nancrede, Chas. B., M. D.—Essentials of Anatomy, 623.
Ott, Isaac, M. D.—Modern Antipyretics, 178.
Post, Sarah E., M. D.—Massage, 137.
Potter, George William, M. D.—Ministering Women, 746.
Powell, Wm. M., M. D.—Pocket medical formulary, 1015.
Roberts, Sir William, M. D., F. R. S.—Digestion and Diet, 105.
Robinson, Fred. B., M. D.—Intestinal Surgery, 944.
Shuttleworth, E. B.—Notes on New Remedies, 577.
Sisley, Richard, M. D.—Influenza, 860.
Taylor, J. J., M. D.—The physician as a business man, 1014.

Warner & Co.—Therapeutics Handy Reference Book, 69.
Wharton, Henry R., M. D.—Minor Surgery and Bandaging, 506.
Willard and Adler—Anæsthetics, 826.

Boone, D. W., M. D.,—New instrument for the application of ointment to the urethra, 576.
Borax in the treatment of epilepsy, 137, 464.
Borck, Edward, A. M., M. D.—Abdominal uterine tumor, 373.
Boric acid, etc., as food preservers, 275,
Bowel resections, statistics, 431.
Bowel troubles in children, 524.
Boyle, H. A., M. D.—Dislocated vertebra, 563.
Brain Surgery, present status of, 615, 792.
Brain, penetrating wound at base, 1004.
Brand, method of, in typhoid fever, 173.
Brass moulders' disease, 422.
Breast amputations, statistics of, 188.
Bright's disease, pepper and mustard in, 319; urethane in urine, 35.

Brinton, John H.—Stricture of the male urethra, 601, 641.
British Medical Association, 38.
Bromide of ethyl in epilepsy, 344.
Bromoform as a topical application, 462.
Bromol, 72.
Bronchitis, bananas in chronic, 383.
Brown, E. J., M. D.—Milk as a medium of contagion, in typhoid fever, 210.
Bruit, presystolic, 224.
Bryonia alba as a remedy, 945.
Buboes, abortive treatment of, 832.
Bull nettle, a new alterative, 426.
Burns and scalds, treatment, 983.
Burns, iodoform for, 425.
Burr, Wm. H., M. D.—Letter, 423.
Butter and oleomargarine, test for, 119.
Butter, to distinguish from margarine, 838.

Cactina, a new cardiac stimulant, 107.
Cæsarian section, 32; indications for, 835; unique case, 116.
Calculus, urinary, present status of treatment, 713.
Campbell, E. N., M. D.—Thorough diagnosis, 1007.
Camphor, a solvent for iodoform, 237.
Camphoric acid in night-sweats, 24.
Camphor, poisoning by, 72.
Canadian medical certificates, 38.
Cancer, grafts and inoculation in man, 679, 908; new treatment, 548; of the breast, recurrence of 657; of breast, 441; of pancreas, 91; parasite, 237; treated by pyoktanine, 578.
Canfield, Wm. B., M. D.—Valvular disease of the heart, 361.
Canned meats, ptomaines and bacteria in, 399.
Cantharides in carcinoma, 540.
Carbolic acid, as a local anæsthetic, 540; creolin and lysol, 677; destructive action of, 983.
Carbuncles, treatment by extirpation, 351.
Carbon dioxide register, automatic, 878.
Carcinoma, cantharides in, 540; metastatic, 468; uteri, early diagnosis of, 1020; of the œsophagus, 1002.
Cardiac impulse and respiration, 670.
Care, J. R., M. D.—Clinical observations of acetanilide, 729.
Carrell, J. B., M. D.—Obstetric anæsthesia, 731.
Castration and salpingitis, 470.
Cataract, senile, 450 cases of extractions, 1019.
Catheterismus, posterior, 28.
Cauda equina, diseases of, 25; surgery of, 431.
Celluloid plates for closing trephine openings, 468.
Centrifugal force in clinical diagnosis, 350.
Cervix uteri, amputation of, 609; immediate repair of lacerated, 632; relation of laceration of the malignant disease, 328.
Cerebral hæmorrhages caused by convulsions, 385.
Cerebral surgery, 430, 792.
Cerebro-spinal meningitis, iodol and antifebrin in, 546.
Change of ownership of REPORTER, 541.
Chapman, W. Carroll.—Toxic effect of tobacco vapor, 653.
Chatinine, an alkaloid for valerian root, 236.
"Chemical Romance", 279.
Chemistry of the stomach in infants, 756.
Chenoweth, W. J., M. D.—Collodion and rubber adhesion plaster as surgical dressings, 288.
Cheyne–Stokes respiration, etiology of, 387, 671.
Chilblain of the lip, 830.
Childhood, headaches of, 79.
Children, common errors and fallacy in treatment, 874; bowel troubles in, 524.
Chinese cement, schio-liao, 559.
Chloralamide compared with chloral, 747; physiological study, 382; in epilepsy, 1015.
Chloral-phenol and phenol camphor, 276.
Chloride of methyl as a local anæsthetic, 548.
Chloroform, anæsthesia, nitrite of amyl in, 831; chrystalized, 37; in labor, 851; in obstetrics, 31; purification of, 439; narcosis, test for complete, 714.
Chlorophenol, 990.
Chlorosis, treated by subcutaneous injections of iron salts, 382.
Cholera, in Asia Minor, 198; at Kurnool, 238; in China and Japan, 839.
Cholagogue, salicylate of soda as, 138.
Chorea, analysis of 260 cases, 829, 948; antipyrin in, 787; pathology and treatment, 269; relation to rheumatism and heart disease, 74.
Cinchona crop of Java of 1890, 839.
Citric acid a normal constituent of milk, 798.
Cleanliness, 153.
Clinical thermometers, spreading disease by, 276.
Club-foot, forms of, 882.
Cocaine, as an anæsthetic, 179, 377; and bromide of sodium incompatible, 358; and morphia, serious symptoms from, 139; habit, 710; in urethral surgery, 588; modification of Fereira's test for, 318; poisoning, 645; administration, 1016.
Coca leaves, new alkaloid from, 337.
Cœliotomy for rupture of the parturient uterus, 717.
Coffee, its use and abuse, 396; manufactured, 237.
Cold drink as antipyretic, 20.
Collodion and rubber adhesion plaster as surgica dressings, 288.
Colotomy, 415; inguinal, 832.
Colpo-perineorrhaphy, 605.
Comparative cost of medical education in America and England, 37.
Congress of American Physicians, Second Triennial, 156, 400.
Congress of American Physicians and Surgeons, 400.
Conium seeds, new alkaloid from, 358.
Conjunctivitis, in children, new method of treating granular, 1018, 394; and iritis, differential diagnosis, 467.
Conklin, Wm. L., M. D.—Appendicitis, 445.
Conner, P. S., M. D.—Late manifestations of syphilis, 569.
Conrad, J. Reed, M. D.—Obituary, 380.
Consanguinity, conception and malformations, 278.
Constipation, 84; a cause of typhlitis, etc., 761; a cause of cerebral hæmorrhage, 385; as a cause of cerebral hæmorrhage in early life, 275; in children, treatment of chronic, 874; in children, abdominal massage for, 717; in relation to pelvic diseases in women, 273; treatment of chronic, 381; opium in chronic, 981.
Consumption, prevention of the spread of, 594.
Contract practice in Berlin, 258.
Convulsions, trephining for, 1019.
Copper, arsenite of, 136; detection of traces in distilled water, 1023.
Cord, trophic centres in, 480; in prolapsed funis, improved method of managing, 31; velamentous insertion of, 150.
Cornea, nerves of, 465.
Corpora quadrigemina, diseases of, 986.
Corpuscles, regeneration in oligæmia following poisoning by pyrodin, 223; nucleated red in anæmia of children, 34.

Cortical myelitis, 521.
Couch, a room only half furnished without one, 920.
Cough, mustard plaster as a remedy, 861.
Coxitis, gonorrhœal, spontaneous luxation, 1017.
Creasote, 944.
Cremation in Argentina, 158.
Creolin, carbolic acid and lysol, 677; for chronic eczema, 381, 425.
Croonian Lectures, 80.
Croupous pneumonia, etiology of, 473; treated with digitalis, 118.
Crural assymetry and lateral curvature, 698.
Crystalline lens, removal in high degrees of myopia, 934.
Cummings, J. D.—Amputation of the cervix uteri, 609.
Curarine, production of, 719.
Curriculum, five years, 36; ten years, 36.
Currier, John M., M. D.—Whooping cough and its treatment, 934; two cases of heart-failure, 380.
Cystitis, treatment, 963.
Cystotomy, for removal of vesical tumor, resection of the pubis in suprapubic, 315; vaginal, 833; suprapubic, 970.

Dana, Charles L., M. D.—Sexual neuroses, 241.
Darling, Horace L., M. D.—Skin-grafting, 484.
Decidua, tumors of, 592.
Deformity after knee-joint incision, 699.
Delafield, Frances, M. D.—Clinical Lecture, 83, 1001.
Delirium of influenza, 223.
Delivery, right occipito-posterior, 443.
Dental asepsis, 718.

Clinical Lecture.

PERI-UTERINE INFLAMMATION.

BY BROOKS H. WELLS M. D.,

LECTURER ON GYNECOLOGY AT THE NEW YORK POLYCLINIC—FELLOW OF THE NEW YORK OBSTETRICAL SOCIETY—NEW YORK ACADEMY OF MEDICINE, ETC.

Gentlemen:—I am fortunate in being able to bring before you this morning several cases that illustrate in a very typical manner the more common forms of peri-uterine inflammation, and which will furnish us with an opportunity for a brief sketch of some of its more salient points. This pathological condition may, for the sake of demonstration, be broadly divided into two classes, viz., acute and chronic. Most cases of peri-uterine inflammation begin acutely, and, after a time, develop into a condition which may be termed chronic, although that term is not a strictly correct one. Others begin insiduously, and are only discovered after they have existed for a period of months or years.

The pathological conditions to which I wish to direct your attention are those described in the books under the various names of peri- and para-metritis, both acute and chronic, and the various ferms of salpingitis. These different conditions, as viewed from a clinical standpoint, are often associated, and the result of a fairly definite sequence. Thus, we will have an inflammation of the mucosa of the uterus, of the tube mucosa, then of its peritoneal covering, the peritoneum adjoining, together with an exudation of coagulable lymph into the adjacent cellular tissue, and into the cavity of the pelvic peritoneum. The lymph in the meshes of the cellular tissue, which is at first fluid, coagulates and may finally be entirely absorbed, leaving only a slight contraction over the area involved. The peritoneal lymph coagulates into the firm, glue-like masses that you are all familiar with, becomes partly absorbed and partly organized into connective tissue containing many lymph spaces, and binds down by its contraction the uterus and appendages to the adjacent peritoneal surfaces. Occasionally, these cases begin as a true cellulitis with effusion into the sub-poritoneal connective tissue, which may be either absorbed, leaving finally only a contraction and thickening of the base of the broad ligament, or may go on to suppuration and the formation of pelvic abscess. Pelvic abscess also often results from the rupture of a pyo-salpynx between the layers of the broad ligament.

Sepsis is the great etiological factor in the causation of these inflammations. This sepsis may be produced either by the decomposition of blood-clots, or retained bits of the fœtal envelope after abortion or labor at full term, by a catarrhal or gonorrhœal endometritis, or by the introduction of septic material into the uterine cavity, or by instruments, or fingers, that are surgically unclean.

These are the most common causes of periuterine trouble.

Less frequently, the inflammation is tubercular, mycotic, or the sequela of one of the zymotic fevers, particularly scarlet fever.

"Catching cold" is held by many eminent authorities to be a prolific cause of peri-uterine trouble in women who have been previously healthy, but personally, I believe that this, in the absence of any previous pathological condition of the mucosa of the uterus or tubes, is a factor of very slight etiological value. It is unquestionably true that any ordinary catarrhal endometritis may extend to the tubes by direct continuity of structure, and this extension would be favored by cold and fatigue, or by any agent which might produce a temporary depression of vitality.

True cellulitis is practically always the result of a direct infection of the tissues through a wound of the cervix or vaginal

vault opening into the lymphatic spaces, and this usually occurs after delivery, more rarely after other mechanical injuries to the cervical tissues.

I will now bring before you a patient who presents a characteristic picture of acute peri-uterine inflammation following abortion; a woman who had previously had no pelvic trouble. She is twenty-four years of age; she has been married three years and has given birth to one child, a boy who is now eighteen months old, and whom she suckled for a year. After weaning him at the end of this time she menstruated regularly until six weeks ago when she missed a period. She dreaded pregnancy, but denies having done anything to bring on an abortion.

According to her statement, eight days ago, she began to suffer severe, cramp-like pains, and, at the same time, began to have a rather profuse, bloody discharge from the vagina. The cramp-like pains lasted for several days and then disappeared, after the expulsion of what she terms a "bit of flesh." The bloody discharge, however, continued, and during the last few days it has been attended with an offensive odor. Last night she felt chilly, then hot and feverish. The pains have returned and are now felt as a severe, constant ache all over the lower pelvic region; more intensely on the left side, and with occasional exacerbations of greater intensity. She also complains of severe pain on defecation or micturition and her temperature by the mouth is now $102\frac{8}{10}$.

On bi-manual examination, I find the uterus in a normal position, but enlarged, soft, tender and immovably fixed in the pelvis by a well-marked swelling on the left side, filling the space above the vaginal vault and extending back of the uterus into Douglas' pouch. On the right side there is a moderate amount of thickening about the appendages, but not so marked as that on the left, where the area of exudation is doughy, œdematous to the touch, exquisitely tender and hot. The vagina is bathed in an abundant reddish, fœted discharge. The cervical canal is dilated so as to easily admit the finger tip. While it is important to subject this woman to no unnecessary manipulation, it is absolutely requisite that we satisfy ourselves that the uterus is empty and that there is no further source of sepsis in its cavity. By reason of the dilatation of the cervical canal and the offensive odor from the vagina, I suspect the retention of some portion of the ovum, and with this dull curette I will now gently explore the entire cavity. The patient is very plucky and keeps quiet, otherwise we should have to use chloroform. This procedure is always best done at the patient's home, when practicable.

I now remove with the curette, as you see, these little masses of decomposing placental tissue and decidua, which seem to be all that have remained in the cavity of the uterus. It is now important to complete our work by irrigating the uterine cavity thoroughly with an antiseptic solution so as to wash away any debris that may remain there, and to render the cavity, as far as possible, aseptic. For this purpose, I will employ a bichloride solution of the strength of 1–4000, injecting it through this small glass catheter. You will notice that the cervix is freely enough dilated so that there can be no obstacle to the return of the water. This is a very important matter for us to know, for if we should inject any fluid into the cavity of the uterus, we might readily force a small amount of septic material, or some of the injected solution, into the tubes, and do serious damage to the patient. In private practice, it would be a much better plan to send this patient home, give her an anæsthetic and perform this operation of curetting and washing out the uterine cavity there. It is essentially important in this operation that the strictest antiseptic precautions be enjoined and carried out by the operator, as our object is to render the uterine cavity thoroughly aseptic, and so remove the materies morbi which gives rise to the fever, and which has already undoubtedly extended through the tubes, giving rise to a localized peritonitis. After the uterine cavity has been thoroughly cleansed in this way, the patient should be kept in bed and no further local examinations resorted to, A gentle, warm douche of a pint or two should be used twice daily for cleansing purposes. She should be kept quiet in bed for from two to three weeks until all the acute symptoms have completely subsided and the exudation markedly diminished. As long as any fever persists, an ice-bag should be kept over the suprapubic region. When the temperature drops to normal, you will find that hot poultices will afford her the most efficient relief from pain. At a later period, strong counter-irritation over the utero-ovarian region such as a blister, will give you the very best results, both in the way of relieving the pain and promoting the absorption of the peri-uterine exudation. The bowels are to be kept open by small doses of some saline laxative. For the relief of pain, I have found the most efficient agent to be

phenacetine in fifteen grain doses, in combination with from a half to one grain of codeine. Prolonged hot douches are not well borne until after the acute stage has passed. They are then useful in relieving pain and promoting the absorption of the exudate.

Our next patient illustrates a chronic condition of this same trouble. Her history at first was similar to that of the patient who has just left us. She now complains of pain low down over the sacrum, over the ovarian region, and pains of a bearing down character. She tells us that she has not been well since her second confinement.

Many of these patients come here with no history at all of any inflammatory trouble, and it often requires very careful questioning to determine when the initial inflammatory trouble began.

On bimanual examination I find the uterus displaced downward and backward, and but very slightly movable, being fixed by the adherent appendages and by direct adhesions to adjacent peritoneal surfaces. On either side there is an indurated, somewhat indefinite thickening extending down towards Douglas's pouch, where I can feel two fixed, exquisitely tender bodies, the prolapsed and adherent ovaries, the lateral masses being the thickened, convoluted and adherent tubes. There is considerable tenderness on pressure over the vaginal roof in the neighborhood of these masses, and any attempt to move the uterus gives rise to considerable pain. The patient tells me that she suffers an excessive amount of dispareunia. This difficulty is due to the fact that both ovaries are prolapsed, adherent and acutely intolerant of any mechanical pressure. The pain she complains of on defecation, when at all constipated, is due to the same cause, the hardened fecal masses as they pass down the rectum pressing against the adherent ovary on the left side, she also complains of a profuse, glairy and sticky vaginal discharge, and on examination with the speculum I find the os reddened and eroded. The cavity of the cervix is filled by a mass of thick, tenacious, brownish-yellow mucous, pathognomonic of a cervical endometritis.

These patients can often be greatly benefited by painting the vaginal vault with a strong solution of the tincture of iodine twice a week for months, and following this by the introduction of a tampon saturated with pure glycerine or boroglyceride. These tampons should be permitted to remain in position for twenty-four hours and then removed, the patient being instructed to wear a napkin in the meantime to prevent the profuse serous flow, caused by the glycerine, from soiling their linen. After the removal of the tampon in the morning, the patient should be directed to use for at least twenty minutes, a hot water vaginal douche at a temperature of 110° F. This can be done by means of a fountain syringe or syphon apparatus. These douches are best given with the patient lying on her back, with the hips elevated and supported by a hospital bedpan.

If the patient is so situated that she cannot come to your office frequently, she is to be told to use the hot douche every morning, and afterwards, to inject through a small glass syringe into the vaginal fornix, a dram of pure glycerine, or she may be directed to use glycerine vaginal suppositories. Tincture of iodine should be painted over the skin in the ovarian regions daily, unless it produces too much soreness. If the pain be severe, a series of blisters applied over the same region will be found very effective. Such treatment as this must be persisted in for months, and in a fair majority of cases, great relief, and often symptomatic cure will be the result.

The next patient is an unmarried girl nineteen years of age, who suffered from a moderate dysmenorrhœa. She comes to-day complaining of trouble that commenced with a slight chilliness, fever, pain and tenderness over the region of the appendages, following the use of the sound by a physician who, she says, took it from his pocket to introduce it, and again returned it after simply wiping it with a dry towel. She now feels weak and miserable, though still attending to her duties as housemaid. Bi-manual examination is different in this case, because of the tense abdominal walls and the tenderness of the parts. The uterus, however, we find to be sharply anteflexed and fairly movable, though any attempt at motion gives rise to pain. Laterally, we find great tenderness and some thickening of the uterine appendages. Such a pathological condition as this is often found associated with slight septic infection from careless gynecological manipulation, and affords us, as in this case, a striking illustration of the necessity for more careful asepsis in ordinary gynecological examinations. It may be safely said that if we can be sure that the vagina, cervix, instruments and fingers are thoroughly aseptic, we will very rarely produce such a pathological condition as is present here.

The treatment of this patient is best in

bed, the icebag over the supra-pubic region, and aconite or pulsatilla internally, while there is any fever present. Under the use of these remedies, the pain will probably soon disappear and the slight thickening of the appendages clear up together. The more marked examples of this condition pass into the chronic form, as illustrated in the case of our second patient, and then require the same course of treatment.

The next patient furnishes us with the history of a but too common affection in women, and clearly illustrates the deplorable effects of gonorrhœal affection. She is a woman twenty years of age and was married eleven weeks ago. Her husband, who comes with her to the clinic to-day, acknowledges that he had a gleety discharge at the time of his marriage. The wife rapidly developed an acute, gonorrhœal vaginitis, which was treated by her physician, and about the time he thought he had brought the disease under control, the woman began to complain of a sense of pain over the lower part of her abdomen. She had a slight fever, and some chilly sensations, and on local examination a condition was found for which she was referred to this clinic for treatment.

On bi-manual examination I find that the tubes, which I happen to know were in a perfectly normal condition at the time of her marriage, are now very tender, enlarged, and, as distinctly mapped out by the finger tips, stand like little sausages on either side of the uterus. They are free from adhesions and are perfectly movable, typical examples of a pure, acute salpyugitis.

If we treat this patient by rest, blisters, etc., her pain will become less, and she will be symptomatically fairly well, but those distended tubes will be still there, and after some slight exertion, there will be a leakage from their fimbriated extremities, which will result in a return of the pain and fever, to again subside after a time. She will develop a series of such recurrent attacks, and we will then find that the tubes, which at first were movable, are becoming more and more bound down by the effused lymph, until finally there will be only a firmly fixed, shapeless, tender mass to the sides and back of the uterus. All cases do not fortunately run so serious a course, but for many this picture is not overdrawn. I have seen three such cases during the past few months, all of which followed the same course. The ordinary treatment benefits them only temporarily, but does not cure the disease, or prevent the recurrences, which, at any time, may develop into a general peritonitis and kill your patient. In such instances as this laparotomy is the proper therapeutic course to follow, delay is dangerous and only renders the removal of the diseased appendages more difficult from the formation of increasing adhesions. It may be safely stated that if a patient comes to you with a history of oft-recurring attacks of localized pelvic inflammation, and, on examination, you find the tubes markedly enlarged, tender, prolapsed, and more or less adherent, you are fully justified in advising their prompt removal.

Apropos of this case, I may here speak of the general laxity and indifference with which many physicians regard the presence of a slight, gleety discharge in a man who contemplates marriage. He is usually told by his physician that there is no danger of infection of his wife. He accordingly marries, and the woman who had been previously in perfect health begins to suffer from increasing pain at her menstrual periods. She gives birth to a child, and after the birth of that child, even though the strictest asepsis be maintained at its delivery, she develops an attack of acute salpingitis, and is ever afterwards sterile. Or, perhaps, she does not conceive at all, but complains of increasing peri-uterine pain until finally an examination reveals a thickened and tender tube or tubes. She has recurrent attacks of acute localized peritonitis and finally comes under the knife of the surgeon.

These cases are not in any way exaggerated instances of this condition, and they go to prove that gonorrhœal infection persists, in many cases of gleet, with at least enough virulence to render the individual a dangerous husband. For this reason no man with gleet should be allowed to marry while such a pathological condition persists.

The more acute forms of gonorrhœal vaginitis are seen in young women in whom the vagina has not been toughened by repeated coitus, astringent injections, etc. In prostitutes and older women of unclean habits, gonorrhœa may, and often does exist, without any appreciable vaginitis, the vaginal mucosa being so toughened and resistant to the action of irritants that the gonococcus can make no marked impression. These women on superficial examination, may appear to be healthy and yet, because of the presence of the gonorrhœal virus in the secretion of the cervix or endometrium, they are perfectly capable of transmitting the disease to a healthy individual. This is a clinical fact that is often over-looked, and yet is a matter of very great practical im-

portance. In any of these forms, the disease, of course, may at any time pass up the endometrium and into the tubes.

Any of the zymotic fevers may cause tubal inflammation, though authentic cases are rare. One that I now recall was in the case of a clergyman's wife who came to me for advice. She had been married nearly a year, and, on examination, I found a thick, fleshy hymen, through which I could not pass the tip of my little finger. There was also a very marked vaginismus present. The hymen was incised under chloroform, the vaginal orifice dilated, and vaginal examination revealed a large, sausage-shaped tumor on either side of the uterus. On questioning the patient afterwards, I learned that she had had a severe attack of scarlatina when 16 years of age, and since that time had suffered from scanty, painful and irregular menstruation. She was treated for a period of 18 months in the manner I have previously described and felt very much improved as a result. She subsequently became pregnant, but about the sixth month of pregnancy developed an excessive degree of hydramnion and miscarried.

The last patient I show you to-day exhibits a pathological condition known as chronic pelvic cellulitis. Chronic pelvic cellulitis is much less frequent than was formerly supposed, and occurs after injuries of the cervix or vaginal vault during labor or abortion, or after operations involving some traumatism of these parts. It often begins with a chill, a marked rise of temperature, and severe local pains. The vaginal vault on the affected side is depressed, boggy and tender. The pelvis is filled with a mass that often extends into Douglas' pouch, and the uterus is fixed and immovable. The infiltrated tissues are at first doughy, but soon acquire a characteristic woody hardness. This exudation is usually absorbed, leaving behind only thickened, contracted bands along the base of the broad ligament, such as we find in this case, or it may break down and form a pelvic abscess.

The treatment of this condition, while acute, is similar to that of the first patient I presented to you, unless it should break (suppurate) when an incision and drainage through the vagina or abdominal wall would be necessary, as soon as the presence of pus could be detected.

In the treatment of all these cases you must not forget the importance of maintaining the general nutrition of the patient at as high a plane as possible. Any systemic dyscrasia must be looked after and corrected. Good food, general tonics, fresh air, cheerful surroundings, oxygen and iron are the most useful therapeutic measures at our command. Local complicating lesions must be attended to, as, for instance, an hyperplastic endometritis, with severe metrorrhagia. Here, careful dilatation and curetting, *under strict antiseptic precautions*, will often help in a very remarkable manner in improving the patient's condition.

Another point I wish to impress upon you in this connection is: Do not submit patient's who have peri-uterine trouble to frequent and unnecessary manipulations. After you have once made your diagnosis, do not examine your patient every time you treat her, but only so often as it is necessary to ascertain progress in the case. Warn these patients against violent or frequent sexual intercourse, against heavy lifting and the use of tight clothing, or corsets. Do not be too anxious to perform laparotomy, for, though it may not be so brilliant an undertaking to make use of a tedious course of treatment in these cases, it is in the long run more satisfactory to them and will reflect much more credit upon you. If the patient does not improve after a time, if she continues to suffer very severe pain or has recurrent attacks of local peritonitis, then, you can always advise the radical operation. It has been my experience that many patients who suffer pain from firmly adherent appendages, do not get the relief that you would expect from their removal. This is often due to the fact that the raw surfaces left after peeling the tubes loose from their attachments, furnish tempting opportunities for stray intestinal coils to enter into undesirable alliances; connections which are difficult to prevent and to remedy.

Some of the more important lesions taught us by the study of periuterine inflammations are; that we should always use most careful antisepsis in dealing with the female pelvic organs, that we may not cause harm instead of good.

In incomplete abortion, to remove the remnants at once.

Do not let your male patients marry while they still have an "innocent gleet."

Be patient and persistent in treating obscure tubal troubles, and, as a rule, do not be in a hurry to advise or perform laparotomy.

FOR WARTS AND CORNS.

An excellent remedy for warts and corns, is a solution of salicylic acid in flexible collodion. A saturated solution is best.

GENU VALGUM—HYDROCELE—FRACTURED RIB—ISCHIO-RECTAL ABSCESS.

BY ERNEST LAPLACE, M. D.,

PROFESSOR OF PATHOLOGY AND CLINICAL SURGERY AT THE MEDICO-CHIURGICAL COLLEGE OF PHILA., AND SURGEON TO THE PHILDELPHIA HOSPITAL.

[AT PHILADELPHIA HOSPITAL.]

Here is a little boy I wish to bring before you, and on whom I hope soon to operate. The child has knock-knees or genu valgum, and I would like to tell you what that is, and just how it it is formed and what is the operative procedure to remove the deformity.

This child has a puny appearance, and on looking at its face, you get a clue to the cause of the condition. Open your mouth. He cannot open his mouth very widely, and on examining we find that there are cicatrices which prevent him from doing so. On looking at them carefully you will find that they have the typical appearance of scars resulting from mucous patches. He has inherited syphilis. He had Hutchinson's teeth, but they were removed. See these cicatrices, with a perfectly white base and a certain amount of fibrous tissue all around. You find that he has also had a form of bone trouble—osteo-myelitis—common in children, especially those who have inherited either the syphilitic or tuberculous diathesis.

The child has also genu valgum. What is the pathology and how does it come to pass? You all know how bones grow. You know they grow in their continuity and in their width; that at the end of the bones is an epiphysal cartilage, which is plentifully supplied with blood, and that the cells in it are in an active state of proliferation. This cartilage exists at each end of the bone and its cells grow by a phenomenon called karyokinesis, that is a splittting up of the nuclei and cell into two. These cells accumulate on the surface of the cartilage, and that is how the bone grows in its length. In its width it grows by means of the periosteum and endosteum.

What we wish to see now, is the part which this epiphysal cartilage plays in producing genu valgum. In a person who is perfectly healthy, whose cells develop uniformly and equally, the cells grow evenly to the right as the left, forward as backward; hence, as a result, the limit remains straight. If, on the contrary, the patient suffer from some diathesis, some impurity of the blood, or some disease of the cells, (which originally may have been very few,) it is possible and it does occur that some cells are not healthy, and not able to develop new ones as they ought to be. Here on the underside they develop as they should, but, to the outer side, they do not develop so regularly; less of them are produced in a given length of time than are produced on the inner side and, as a result, there will be an accumulation of cells here and a thin layer outside, just as if a wedge were put between the bone and epiphysal cartilage, pushing the limb out. When we have the condition known as bow legs, it is the opposite to that which has taken place, and instead of thickening taking place to the inner side, it is outside. Therefore remember that this is a fault of nutrition, of develpment of the epiphysal cartilage and, as a result, this deformity takes place. The treatment is entirely an orthopædic one; the surgeon directs his attention to remedy the deformity. He ought to bear in mind the diathesis which predisposes the affection. In this case we recognize the syphilitic diathesis and we ought to proceed cautiously, and give the child the benefit of all that we know. Bearing this in mind we proceed to the remedial measure, which consists simply in making the limb straight, if possible. There is only one way to do this, and that is by breaking the femur above the condyles, treating the case subsequently as a fracture of the lower third of the femur. How are we going to reach this end? We know how fractures are produced by a fall, by an extra amount of force on a particular spot. Therefore, instruments have been devised whereby the limb is held fast while the end of it lifted up, thus producing fracture. This operation is osteoclasia, the instrument the osteoclast. That operation was in vogue before the triumph of antiseptic surgery, for by it the surgeon had no external wound, but such great force has to be applied in order to obtain the result, that the tissues necessarily were much contused and the nerve vessels run great risk of being injured, so that this operation is gradually sinking into disuse, owing to the gradual advance of antiseptic means of operating. The operation now resorted to is simply to cut upon the bone, denude it of its periosterim, and, using chisel and hammer, remove a wedge-shaped piece of bone, or cut partly through, and, with a slight effort, break it. You have practically obtained the same result as you would have obtained from the osteoclast, without the bruising of the tissues. Then close the wound with a dressing that excludes the atmosphere; use Plaster of Paris dressing

or ordinary fracture splint, and in a month or two the limb is healed and straight. Finally, the patient, especially if both limbs are operated upon, is taller than before the operation, because a straight line is the shortest distance between two points. The modern treatment, therefore, is osteotomy; the case being transformed into an aseptic compound fracture—which to-day seldom implies more risk in prognosis than a simple fracture.

Hydrocele.

No case in surgery, however insignificant, is devoid of points from which a great deal of knowledge may be gathered. If we only knew everything about the very simplest case, we would be much further advanced than we now are. You know how to diagnose a case, and think it apparently simple, but push your research to the bottom facts and you will certainly be puzzled.

So here is a case of hydrocele in a very healthy man, a sailor. A bag fell upon him, causing a traumatism over the testicle and, as a result, there is a swelling. A swelling in that region can be one of only two conditions, either an inflammation of the gland from direct injury, called orchitis, or an inflammation of the serous membrane covering the gland, causing an effusion of serum within that closed sac which was originally a portion of the peritoneum called the tunica vaginalis. The serum gathering within this sack, forms a tumor (hydrocele) over the testicle, not a tumor of the testicle itself.

Now let us see exactly the anatomy of the the parts. The spermatic cord running up with its vein and artery; the peritoneum coming down and being reflected over the surface of the testicle exactly as the serous membrane is reflected over the ribs and the lung; above the testicle the layers becoming adherent and forming a single layer from the top of the testicle up to the internal abdominal ring, over the testicle a capacity for containing water. The meaning is conveyed to you by the idea of an empty leather bag. So here it is closed, but with a capacity for holding fluid. If inflammation be excited about the sac, it will cause fluid to be poured into its cavity, which we then call a hydrocele. When this fluid is limited to the cavity extending from the bottom to the top of the testicle we simply call it a hydrocele, a fluid tumor in the tunica vaginalis testis. But there are cases where the adhesions between the inner and outer layers of peritoneum over the cord are destroyed and exudation of serum between them causes a tumor extending to the top of the cord, near the external inguinal ring. In these cases we have a tumor, as we see in the man before us, extending from the bottom of the testicle to the external ring—a hydrocele of the cord.

The most frequent cause of hydroceles, both of the testis and cord, is a chronic inflammation directly or indirectly coming from old gonorrhœa. Remember that in this case, as in every other case of irritation of any part of the body, the primary agent is an irritant which causes congestion of the blood vessels, just as when you put a blister on the surface of the skin and cause the serum to come out on the surface and form a bleb; so here, on irritation, the serum comes out and forms a tumor. The irritation need not necessarily be gonorrhœal, but may be a traumatism, which produces nearly the same thing; it produces a blister such as you get from using the oar. So, also, a traumatism to the tunica vaginalis testes will produce a similar blister.

How do I diagnose a hydrocele of the tunica vaginalis testes and how do I distinguish it from a hydrocele of the cord?

According to our theory as to the respective locations of hydroceles of the tunic of the testes and cord, if this involved only the space between the upper and lower borders of the testicle we would have hydrocele of the tunica vaginalis testes only, but as the tumor extends to the external ring, we have hydrocele of the cord also.

Again, on making gentle pressure above between the finger and thumb of one hand, and placing the other hand on the lower part of the tumor, the impulse or sensation of fluctuation is distinctly felt below, showing the presence of fluid and showing also that the cavities communicate.

The diagnosis having been made, we will wash the surface of the testicle and puncture the hydrocele.

Remember that any discharge which we may have in surgery derives its color from the blood; therefore, in traumatic hydrocele the color of the fluid is deeper, the more recent the traumatism. If this hydrocele had been punctured immediately after the traumatism it would have been much more like blood. The direct result of the traumatism here was an effusion of blood; clots were formed, and the serum from the blood is what we have just drained off. As I push the canula lower down, we notice some blood yet coming out of the parts.

What will be the result of our operation? In a case of hydrocele, or dropsy of any

serous membrane, the result to be aimed at is to prevent a return of the effusion, which once having occurred, is prone to recur. To accomplish this, we will endeavor to excite an inflammation in the sac, which shall cause its layers to adhere throughout and thus obliterate the cavity. In hydroceles due to gonorrhœa, different measures have been adopted to effect a radical cure; irritating substances, such as tincture of iodine or carbolic acid, have been injected, or the sac has been scraped. Here, the mere evacuation of the fluid will suffice to obtain this result.

FRACTURED RIB.

The next case is one of fractured rib, which, though a trivial accident, may be the source of a great deal of trouble, and it is in view of the possible complications that we must know how to treat such a case.

Fractures of the ribs are produced by direct traumatism, that is, the patient has received a direct blow; has fallen and struck himself; has been caught by falling masses of any kind, or crushed between cars, etc. It is always a local injury.

The first symptom, which becomes evident to the patient, is a stitch in his side as he takes a deep breath. You can readily see that the rib being fractured and its continuity altered, as the thorax expands one end goes one way and the other another way and it is the friction of these ragged ends of bone that causes the stitch in the side and leads the patient to call for the doctor.

As I press with my thumbs, one over one broken end and one over the other, I felt a grating sensation. This sound, taking place over the lung gives a resonance that is quite peculiar to these fractures.

Let us see what might take place if the patient were not treated, for it is only by knowing this that we can fully appreciate the prognosis in the case, not only when he is not treated at all, but when he is improperly treated. If left alone, and the patient be not warned of the danger, the broken ends of this rib will keep on scratching the tissues, and it would suffice, if the man had any diathesis or cachexia (diathesis meaning an inherited condition and by cachexia meaning an acquired vice of the system due to some disease that he himself had contracted) to set up an irritation; this becoming the spot of least resistance, would be the seat for the manifestation of any vice of the system, such as tuberculosis or syphilis. Not only that, but taking his system to be in a normal condition, these ribs rubbing together would cause irritation of the subjacent pleura—pleurisy—which might soon become purulent and almost destroy the usefulness of the lung. So you see we have a chain of events, the links of which are the result of only a comparatively slight injury. Therefore, you must insist on the proper treatment, which is simply keeping the fractured ends of the ribs in the apposition. You must think of nothing else; put them in splints if possible. To do that, the only way is to bind the thorax and change the form of respiration. You know there are three forms of respiration; the abdominal form, seen in children, where the inspiration is affected by the descent of the diaphragm; the inferior costal type, seen in men, where the inspiratory movements effect chiefly the lower part of the chest wall; and the superior costal type, seen in women, where the movements are chiefly of the upper part of the chest wall. Here we really put corsets on the man; we prevent the chest from expanding by strips of plaster placed about the chest. He will then breathe by depressing the diaphragm. Now there are two ways of putting on these plaster strips. You may apply them only to the affected side, but I take it to be safer to bind the whole chest. Having done this, the man already feels relieved, as the crepitus has ceased.

ISCHIO-RECTAL ABSCESS.

Next I have to show you a case of ischio-rectal abscess. The case has been operated on and is on a fair way to recovery. The abscess has been opened and a large amount of pus evacuated; the case remains, however, very interesting, unassumed as it is one of those instances wherein you see the great simplicity that surgery has at present taken; how affections that were arranged under many different heads, are now classed under one head. If you understand one, you understand all; only the location is different.

This is called an ischio-rectal abscess, because it pointed in the region between the margin of the anus and the ischium. It was a large abscess that did not cause much elevation of temperature and no pain except near the end of its course, when it approached the skin. These have been called cold abscesses, and are found in different parts of the body; at the apex of Scarpa's triangle, called psoas abscess; above Poupart's ligament, called iliac abscess; between the anus and ischium, ischio-rectal abscesses. All these are simply cases of bone tuberculosis. The tubercle bacilli develops somewhere in the back, around or in a bone,

generally starting about a cartilage. It invades the cartilage, destroys it, and then destroys a portion of the bone. There is an accumulation of pus, which is not taken up by the economy, on which account there is no fever. The reason it is not taken up is that the tubercle bacilis grows very slowly; even in the labaratory it takes two or three weeks or a month before we have a growth. So, in the human body, with but few exceptions, it grows slowly. In consumption the patients last for years, so in hip joint disease, when this bacilis grows in the neighborhood of a cartilage. It grows very slowly and there is a formation of a layer of fibrous tissue about it, the so-called pyogenic membrane, an expression of the old patholigists who thought this membrane produced the pus. The fibrous tissue is merely the result of the chronic inflammation and isolates the abscess from the rest of the body; thus it is that the pus is not taken into the general economy and there is no fever from it; it is locked up. Therefore remember why we call it a cold abscess—because there is no fever with it.

Now imagine a bone to become carious (ulcerated), say about the first lumbar vertebra an abscess forms gradually and becoming larger and larger, the mere force of gravitation causes it to pass in the direction of least resistance. If the abscess exists about the region of the psoas muscle, it will dissect the sheath of muscle and follow it to its insertion at Scarpa's triangle and you say the patient has a psoas abscess, which is only the manifestation of a tuberculosis around a vertebra in the lumbar region. On the other hand, you have an abscess which opens above Poupart's ligament, which presents the same greenish pus found in other cold abscesses. This could only start around or at the margin of the pelvis, and burrowing along the iliac muscle, lifts the peritoneum, and opens at Poupart's ligament an iliac abscess. In the case before us, the abscess which was of the same kind, took neither of the courses above described, but opened between the margin of the anus and the ischium. We ask ourselves whence is this pus. It is from a tuberculous process going on at the inner side of the sacrum, exactly where, I cannot tell.

The abscess points wherever it finds the least resistance, so that I have mentioned three manifestations of the same disease, different only because they exist in different localities.

Communications.

RESECTION OF THE OPTIC NERVE.

BY L. WEBSTER FOX, M. D.

(THIRD PAPER.)

Since my first paper appeared on the above subject, I have had frequent inquiries made about the instruments I described, as well as to where they could be obtained in this country. I have had illustrations made of the three most important ones and do not think that a repeated description of them for the benefit of those surgeons who wish to get them, will be amiss.

Fig. 1.

Fig. 1. Represents the duck-bill retractor which is the most important instrument used in the operation. With this, one overcomes the difficulty in keeping out of the way orbital fat and tissue, as well as making more room for the instruments used in grasping and severing the nerve. Being nickel-plated its concave surface acts exceedingly well as a reflecter, which is a desideratum when one is performing the operation with insufficient light.

Fig. 2.

Fig. 2. Is an instrument shaped somewhat like a lid elevator, having inserted, in its concave surface, four or five delicate pin points which are pressed against the eyeball, these points pierce the sclerotic coat but are not long enough to puncture it. The assistant pulls the eyeball around and thus exposes the optic nerve.

Fig. 3. Shows the form of the hooks used in holding the optic nerve, one is right-handed, the mate is left-handed.

The instruments designed by Mr. Carter for opening the sheath of the nerve, are just the instruments most useful in resection. In

fact without them it is almost impossible to perform the operation.

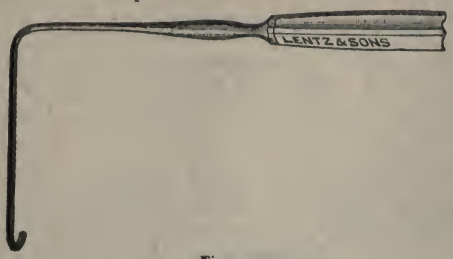

Fig. 3.

For those surgeons who did not read my description of the operation published in the REPORTER of February 7, 1891, I repeat it: "The lids are separated with the ordinary ophthalmostat; a vertical incision is made through the conjunctiva over the insertion of the external rectus muscle; the conjunctiva is dissected off as far back as the external canthus will permit. This exposes completely the muscle. Two silk threads are then passed through the muscle near its tendinous insertion. These threads will be required in a subsequent stage of the operation, to unite the detached muscle to the eyeball. The muscle is then cut and drawn to the temple side. This exposes the globe. With curved scissors, all tissue is then separated from the eyeball. The optic nerve is found by passing a hook, back of the eye-ball,—: a strabismus hook bent at a right angle. This hook brings forward the nerve, and then the retractor is passed downwards until it meets the nerve, and is then pressed down and out, keeping the adipose tissue out of the way. A second bent hook is inserted under the optic nerve, and also passed backward. A certain portion of the nerve becomes exposed, and with a delicate flat forceps the nerve is grasped and held firmly. This is to prevent hemorrhage from the ophthalmic vein and artery (central) after the cut with the scissors. The eyeball is rotated forward, so that the non-severed nerve becomes exposed and a small piece of its bulbar end is cut off. By keeping pressure on the orbital end of the nerve for a few minutes, all danger of hemorrhage is aborted. The eyeball is then rotated into place, and the external muscle re-adjusted. Over this the conjunctiva is replaced, and is held in position with black silk, which may be removed in three days. Antiphlogistic dressings are applied day and night for several days. Very little reaction follows, and in a week or ten days the eye has assumed its normal appearance, with no disfigurement, and the action of the muscle is complete."

Charles Lentz & Son are the makers, and I must say for them that they have reproduced the English models exactly.

ABDOMINAL NEPHRECTOMY, WITH THE REPORT OF A CASE.[1]

[1]Read before the South-Western Ohio Medical Society, at Hamilton, Ohio, April 4, 1891.

BY EDWIN RICKETTS, M. D.,

CINCINNATI, OHIO.

It is quite a coincidence that the first modern splenectomy by Pean, and the first modern nephrectomy by Simon, was done in 1869; both of these men deliberately planned these operations. Walcott, however, in 1860, removed a cancerous kidney, after having made a diagnosis of hepatic cyst. It is not my intention to recite statistics, which are decidedly antiquated, as compared with the results of individual operators, such as Tait, Thornton, Savage, of Birmingham, Morris, and others. Even the results of these men may not be striking, yet they are better than those of older operators. At this time the mortality stands at near 40 per cent. at the hands of the best surgeons. In abdominal neprectomies just now, the results in the hands of a few operators are far ahead of those in lumbar nephrectomies.

CASE.—Mrs. S., aged 33, married, one child eleven years of age. Trouble began in 1880, when she passed bloody urine during attacks of pain located in the region of the right kidney. These symptoms disappeared in time, but she gradually lost flesh and strength up to July 29, 1890, when she called in Dr. J. A. Brown, of Germantown, Ohio, as her family physician. He found her greatly emaciated and decidedly cachectic, with a history for the four weeks past of constant pain in right lumbar region, hectic fever and night sweats; a tender globular mass presented in the right lumbar region, firmly fixed, and extended from the floating ribs to the crest of the ileum forward to within three inches of the umbilicus.

After a few days of observation the opinion was given that it was a suppurating kidney, and an operation for drainage or extirpation was advised. Dr. Donellan was called in and concurred in the diagnosis, and also advised an operation. An effort was made in the way of treatment to improve the patient's general condition by preventing operation, but without any satisfactory result.

No previous history of pus in the urine

could be obtained, nor was pus present at the time of my visit to her, August 19, 1890. At this date I found the condition so tersely described by Dr. Brown, and agreed with him and Dr. Donellan both as to diagnosis and as to the necessity of an operation, notwithstanding the urine was normal in quantity and quality at the present time and had been so ever since the passage of bloody urine ten years before. Upon examination I felt a mass in right lumbar region attached seemingly to the liver; slight jaundice was present, but there was no history of hepatic colic. I advised exploratory incision by way of abdominal section. Consent was given, and I made the operation in the presence of Drs. Brown, Donellan, Horning, and Cochran, the latter gentleman assisting me while Dr. Brown gave the chloroform. I made a six inch incision longitudinally two inches to the right of the median line, beginning at the lower margin of the liver; upon completing my section the right kidney, freely distended and adherent to the liver, was exposed. I punctured it, got pus in considerable quantity, enough to justify an extirpation of the entire kidney, and so proceeded with that object in view. I trocarred all the pus possible after packing sponges about the kidney; I then broke loose the adhesions to the liver, and brought the kidney up into the wound, and ligatured *en masse*, cut away, sponged the surrounding parts well as some pus escaped, and put in a glass drainage tube. At the time of the operation the temperature of patient stood 102.5° F.; pulse 112. The amount of urine secreted during the following twenty-four hours amounted to 40 ounces, and still contained no pus or albumen. By the first week of the following September we had evidence of the presence of a pocket of pus, perhaps at the site of the removed kidney and nearer the lumbar region, where the glass drainage tube could not reach from the front, so we anæsthetized the patient, opened from the back, after removing the glass tube in front, carried one end of a well perforated soft rubber drainage tube through and through from front to back, the ends of tubes being tied to the right side of patient. This gave perfect drainage; warm water was forced through from front to back daily. The temperature and pulse soon dropped, and the patient has improved steadily ever since. She has gained 30 lbs. in weight, and is able to attend to her household duties. An insignificant anterior and posterior sinus discharges a small quantity of thin pus at intervals.

THE PNEUMO-THERAPEUTIC INSTITUTE OF BRUSSELS.[1]

BY DR. HOVENT,

OF BRUSSELS.

Last summer I received a visit from Dr. S. Solis-Cohen, with whom I had already been corresponding on the subject of pneumotherapy. I was gratified by his expressions of astonishment on inspecting the Pneumotherapeutic Institute. I also felt a pride in being able to teach something to a *confrère* from the country whence progress in every science comes to us.

At the request of my guest of some hours, I shall endeavor to describe the establishment with which I am connected, briefly relate its history, and indicate the physiological and therapeutic actions of air-baths.

In 1879, a number of prominent Belgians who had undergone successful aëro-therapeutic treatment at Contrexéville, a French spa, determined to establish an institution for a like purpose at Brussels, and accordingly invited Dr. Tamin Despalles, under whose care they had recovered, and who was already well known through his works on neurology and aëro-therapy, to come and create in Brussels an establishment in which all the improvements in his favorite treatment should be found. The invitation was accepted and a limited society was at once organized. The founder, however, did not long live to see the fruition of his work, and was succeeded in turn by a lecturer at the University, an academician among others, and finally by myself.

The Pneumo-therapeutic Institute of Brussels is the largest and most complete in the world; it is situated in one of the healthiest parts of the city, near a small park. As first constructed, it was intended to practise therapy, aëro-therapy, including compressed or rarefied air-baths, and also anæsthesia by the method of Paul Bert; afterwards, this last method and the azo-therapy were given up and numerous improvements were successively introduced; so that now the establishment furnishes the following services:

1. Baths of compressed or rarefied air, with or without supersaturation of oxygen gas.

2. Inhalations of compressed air with expirations into refined air.

3. The sale of oxygen gas in the city, the country, and even abroad.

[1] Read by Dr. A. A. Eshner, before the Phila. Co. Med. Soc., June 10, 1891.

4. Electro-therapy, by static and dynamic machines.

I have nothing to say upon these three last points. The works of S. Solis-Cohen have elucidated the treatment by pneumatic differentiation better, if with less prolixity, than any author of our continent. To make the establishment complete, it is furnished with the apparatus of Maurice Dupont, Geigel and Mayr, Hovent, Schnitzler, Solis-Cohen, Tobold, and Waldenburg. I use these apparatus, however, only upon request by my *confrères*, because I have personally ascertained that, while they are of real value, yet, as compared with the air-baths, their utility in several directions is very questionable. In this connection a recent paper by my friend, Dr. Arntzenius, of Amsterdam (*Geneeskundige Courant*, 29 June, 1890), is of interest.

Oxy-therapy and electro-therapy are methods of treatment better known and more widely practised in the United States than in Europe. I will, therefore, not consider them.

I now come to the subject which is really interesting to my American colleagues—baths of compressed or rarefied air. These are given by means of seven iron chambers of varying capacity, some being capable of comfortably containing from two to ten persons. Each chamber is very well constructed; it is supplied with several windows of glass, two centimetres (three-quarters inch) thick; it has a double door, or perhaps better expressed, two doors enclosing a lobby, in which the doctor, entering by the outer door, can shut himself, and then equalizing the pressure, can open the inner door and speedily reach the patient for any purpose without great alteration of the pressure in the chamber. Another smaller door, also duplicated, serves for the purpose of handing to the patient books or whatever may be desired. Electric-bell, elbow-chairs, toilet-tables, manometer, thermometer, hygrometer, etc., are all at hand.

From the chamber so described emerge six pipes leading to the underground tanks of 1, compressed; 2, rarefied air; 3, nitrogen; 4, oxygen gas; the last two pipes are for the purpose of purifying the air, of which I shall soon speak. Each of the first four pipes is attached to a little tank which permits of the measurement of the quantity of air, nitrogen or oxygen, introduced into the chamber, or the quantity of air removed.

The large tanks in which the air or gas is compressed, or rarefied, are ten in number. Each holds several thousands of litres. The compression or the rarefaction of air or gas is obtained by means of a gas engine of eight-horse power. The tanks will bear seven or more atmospheres of pressure, or a corresponding degree of rarefaction.

The manipulations are as follows: If it is desired to place the patient in a chamber, and the pipe connecting the chamber with the tank of compressed air, for instance, is opened, this compressed air rushes in; its quantity can be regulated according to circumstances. The reverse takes place if rarefied air is to be used; the air of the chamber rushes out and the patient remains in a relative vacuum.

One serious and even capital drawback to the employment of air-baths lies in the fact that in the course of the two hours, the duration of an ordinary sitting, the air within the cabinet soon becomes foul from the processes of respiration, perspiration, etc. The establishment at Brussels is the only one in which this inconvenience is efficaciously overcome. The air is being constantly withdrawn from the occupied chamber, and purified by being passed through several iron Woltt's jars with chemicals, to be again introduced, the same degree of positive or negative pressure being always maintained.

It may be desirable to impregnate the atmosphere of the chambers with the vapor of certain medicinal agents; it is an easy matter to place the substance to be used in the path of the air current, or more simply to put some drops of an essence in boiling water into the chambers. I frequently and successfully use pumiline essence.

This is, in brief, all that I think necessary to give a fair idea of the application of the air-baths. I shall now consider their physiological and therapeutic action.

To treat this subject at length, as it deserves, would require too much space; therefore, I shall confine myself to an epitome which, I hope, will serve as an index for the reader. In English medical literature I know only of the papers of the eminent C. Theo. Williams (on air-baths; I shall say nothing of pneumatic differentiation). This is in striking and unaccountable contrast with the profuse medical literature of the continent. I shall quote from some of our authors, but chiefly from my personal experience.

The compressed air-bath more completely expands the pulmonary vesicles and increases their elasticity; the diaphragm and the base of the lungs descend lower; the respiratory process is more perfectly and less frequently

performed; the peripheral circulation is less active, with some degree of decongestion of the skin and the mucous membranes (nasal, laryngeal, pulmonary, etc.); the pulse is less frequent and more full; the appetite and strength increases rapidly; the nervous system is undoubtedly invigorated. One may observe that these effects are carrollaries of one another and result either from mechanical or chemical action; indeed, the oxygen of compressed air is no longer oxygen, but some form of ozone.

The rarefied air-bath has not been so well studied; nevertheless, it is employed with much success by some practitioners, who seek in it a reproduction of mountain atmosphere. It has also been recommended for rickety children, when the thorax is deformed. Recently it has been used alternately with the compressed air-bath, when a doubt exists as to whether a patient should be sent to the mountains or to the seashore. The therapeautic use of the air-baths are very numerous, but easily deduced from the foregoing considerations.

Asthma is the principal affection for which compressed air-baths are employed. 80 per cent. of recoveries are obtained after twenty to sixty sittings. During the first sitting the dyspnœa disappears when the pressure of air is sufficient; this result becomes permanent only after a number of sittings. I remember but one case, that of an American patient coming from Oregon, in which the paroxysms reappeared as soon as the pressure was lowered. The patient was very well while under pressure, and I have frequently kept him enclosed for eight or ten hours instead of two. I diagnosticated a traumatic medullary lesion, limited to the respiratory center.

In pulmonary emphysema, the air-bath empties the vesicles and increases their elasticity, so that the dyspnœa diminishes. The first sitting is usually followed by a notable improvement. As in asthma, the success is generally striking and permanent. Pulmonary congestions, pulmonic processes preceding or following pneumonia and hæmoptysis, are cured mechanically, since the compressed air provokes anæmia of the pulmonary tissues. I have some absolutely confirmatory observations. Chronic bronchitis and bronchorrhœa are always improved, so far as concerns dyspnœa, cough, expectoration, and general health. The first effects of the treatment are an increased expectoration up to the point of completely ridding the lungs of mucus, and simultaneously a decongestion of the respiratory mucous membranes. The last action must be invoked in explaining the beneficial influence of compressed air in coryza, chronic pharyngitis and laryngitis, and in that exaggerated susceptibility of the mucous membranes, as a result of which the patient is constantly exposed to the danger of catching cold. I have recorded two cases of chronic amygdalitis, in which resection had been contemplated, and in which I obtained complete cures by compressed air-baths.

In whooping-cough, "the beneficial action of air-baths is undeniable," said Dujardin-Beaumetz. The cure is obtained after ten to fifteen sittings; and generally the child gains from one to three pounds in weight. Joccoud charges with gross neglect the physician who does not submit his consumptive patient to aëro-therapy. Oertel thinks the compressed-air treatment far superior to climatic treatment in any country. Prof. Bertin (Montpelier) has recorded five cases of recovery in consumptives in the third stage.

Heart disease had long been considered the only drawback to aëro-therapy, but since I have successfully treated a number of cases with cardiac complications, I no longer hesitate to treat such cases, only using certain precautions.

In catarrhal deafness compressed air effects a natural catheterism. I have not infrequently seen patients suffering with asthma or other complaints emerge from the chamber declaring that their hearing was better than for many years.

Dujardin-Beaumetz says: "Compressed air-baths are to be preferred to any other method of treating chlorosis, anæmia, diabetes, albuminuria, and gout."

Obesity, also, is favorably influenced as a result of the acceleration of organic combustion and the more active elimination of urea and carbonic acid.

In conclusion, I must add that Dr. Arntzenius has cured some cases of neurasthenia, and that I have recorded three observations of dysmenorrhœa being permanently cured by a pneumo-therapeutic course. I think these results are due to the general invigorating power of the treatment.

If I should quote all the authors who have written upon the subject of air-baths, not only in France, where the treatment was orginated, but in Russia, Scandinavia, Holland, Germany, Italy, and Spain, the list would be a very long one. I wish only to note that none of them has expressed an unfavorable opinion. I am convinced that the treatment which I have expounded is entirely reliable, and I shall be happy if my

paper contributes to make the medical profession of the United States acquainted with the better method of pneumo-therapy.

(For discussion, see Society Reports.)

Society Reports.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, June 10, 1891.

The President, John B. Roberts, M. D., in the Chair.

DR. HOVENT, OF BRUSSELS, PRESENTED A PAPFR ON THE PNEUMO-THERAPEUTIC INSTITUTE OF BRUSSELS.—(See p.11.)

DISCUSSION.

Dr. Thomas J. Mays: I am a firm believer in the efficacy of compressed and rarefied air in all kinds of chest diseases as well as in general disease of the body. My experience has been limited to the use of these agents with the Waldenburg and Cohen-Richardson apparatus. These apparatuses are of value in many forms of lung disease, especially in incipient phthisis, bronchitis, and in asthma. You cannot use rarefied and compressed air indiscriminately. Rarefied air is suited for some conditions, and compressed air for others. I think also that in certain forms of incipient phthisis compressed air will tend to aggravate the disease. If the temperature is above 100° its use will tend to increase it. I have given up the use of compressed air alone, and now employ oxygen and nitrous oxide under pressure, either with or without air.

In Berlin I saw cabinets similar to those described in the paper. They certainly do a great deal of good, but strange to say, most of the writers speak of the value of compressed air without saying much of the value of rarefied air. I think that by immersing a patient in rarefied air you obtain the same effects as you would by placing him at a high altitude. I do not think that the good comes so much from the effect upon the lung as from the influence which is exerted upon the whole body. By taking off part of the pressure from the surface the resistance to the circulation is diminished, and in that way the blood is permitted to reach the periphery and nutrition of the outlying parts is stimulated. I think that in this lies the great and chief value of mountain air in the treatment of comsumption.

The influence of compressed air upon hearing has been referred to. It has been found in the cabinets at Berlin that the compressed air increased the sense of hearing of every one, but, so far as I know, this is only temporary. Those who were hard of hearing will improve for a time, but soon the hearing is as bad as before.

Dr. S. Solis-Cohen: Except from reading, I know very little about this particular branch of pneumo-therapeutics, my experience being confined to the method by which the patient inhales from or exhales into compressed or rarefied air. The method of immersing the patient in an atmosphere of modified pressure requires expensive apparatus, but from what I saw in Brussels, and from the examination of patients with a comparison of their previous histories, I believe that the method accomplishes all that Dr. Hovent claims for it. I went into the cabinet myself, but did not remain long; the noise in the ears and the sense of fulness in the head were sufficiently unpleasant to make one wish to get out as soon as possible. All who have used this method, with the exception of Waldenburg, claim that it is superior to the differential method, though they admit the greater availability of the latter. I have had no opportunity of comparing the two methods, but my experience with the differential method has been thoroughly satisfactory. The remark of Jaccoud, quoted by Dr. Hovent, will well bear repetition; I would, perhaps, slightly modify it and say, "that whoever fails in a suitable case of phthisis to give his patient the benefit of a trial at least of aëro-therapy, fails to do his duty." I do most sincerely believe that the routine writings of prescriptions, with a neglect of the mechanical means so far superior in many cases, is a failure on the part of the medical profession to do its duty toward those whose lives are, humanly speaking, entrusted into its hands, My personal experience now extends over ten years, and I should not like any patient of mine to be deprived of the opportunity of a trial. Inhalation of compressed air will not work miracles. It will not revive the dead. But it will help the patient to fight the disease. It dilates the air-cells, improves the quality and distribution of the blood, and gets rid of accumulaled decomposiug products which may give rise to septic fever.

Dr. James C. Wilson; I would ask whether it is not the experience of patients that after a time these unpleasant sensations, due to disturbance of circulation, diminish?

Dr. Cohen has more right than any one else to arraign the profession for the neglect of these mechanical measures, for he has

been a pioneer in this country, and a consistent practitioner in this particular branch of therapeutics. At the same time, I am at a loss to understand what view a man occupying Dr. Cohen's position can take of the decadence of the enthusiasm which followed the invention of the pneumatic cabinet, four or five years ago. There was, unquestionably, a most excellent device for the practice of such methods as Dr. Cohen advocates. Many medical men availed themselves of this apparatus, but now one hears nothing of the pneumatic cabinet. Many who at first claimed excellent results from the apparatus have abandoned its use.

Dr. Lawrence F. Flick: I have no personal experience with this mode of treatment. I, however, believe with Dr. Mays, that compressed air may do considerable harm in a certain class of cases. I have seen some things in practice which tend to confirm that view. Where the disease is in an acute stage the quieter the circulation the better for the patient. I have seen a case where even a little exertion more than was prudent precipitated a general tuberculosis where the disease had been simply local. I believe that there is a class of cases where the application of compressed air would be of benefit —cases in which the acute stage is passed, and there is considerable material to be gotten rid of.

It seems to me it is hardly fair to arraign the profession for neglecting the use of this method of treatment. It is scarcely right to deal in a general way with this subject without giving detailed accounts of the benefits of the treatment. If such wonderful results are obtained, we should be shown those results.

Dr. Solis-Cohen: In reply to Dr. Wilson, I would say that there is no question that tolerance to the effects of immersion in compressed air is gradually established just as tolerance to the effects of altitude is established.

Allusion has been made to the absence of reports of the effects of rarefied air-baths. These have been tried, but abandoned. Paradoxical as it may seem, it is the compressed air-bath and not the rarefied air-bath that simulates the therapeutic effects of mountain residence. The complaint of Dr. Flick is not well founded. These methods have been in use since 1838, and numerous cases are on record. I have reported a few, but not many, because at this late day it is superfluous.

In reference to the pneumatic cabinet, the methods employed in exploiting it were a sufficient reason why it should not find favor with the bulk of the profession. Then, again, it is a very troublesome and expensive means of doing what can be done much more cheaply and simply. Many physicians of high repute, however, still use it. Among others I may cite V. Y. Bowditch, of Boston. We may rest assured that no physician who has used pneumatic treatment will ever abandon it. The question of apparatus is secondary. The pneumatic cabinet has the same disadvantage that belongs to the pneumatic chamber, and that is, that the patient is compelled to visit the physician to obtain the benefit of the treatment. With portable apparatus, which can be placed in the patient's home, this objection is overcome. If I take any credit to myself it is for simplifying and cheapening the machinery so as to make this possible. As a matter of course, pneumatic measures have their indications and counter-indications, as atropine, morphine, bromides, and drugs in general have theirs. No one uses atropine to produce bromide effects. Air has its definite field of use, just as atropine and bromide have theirs.

Nobody uses compressed air in acute tuberculosis. This was long ago laid down as a counter-indication by Waldenburg and others. It is not to be used in certain diseases of the heart, or in cases with large cavities with extensive septic processes. Between cases with acute processes and the stage of extensive excavation, as well as in the very early stages of so-called incipient phthisis, lies an extensive field for the employment of mechanical measures. They are used not as exclusive measures or panaceas, but to produce certain definite and highly desirable effects that cannot be produced by any other agent; certainly not by drugs, whether creasote or iodoform, hypophosphites, or cod-liver oil, tuberculin, or cantharides. Especially with patients who would be benefitted by mountain climate, but who cannot get away from home, will pneumatic treatment prove a valuable substitute. Some patients have even taken their machines to the mountains, because they dreaded to be deprived of the good effects. I repeat that the treatment works no miracle, but every patient has a right to the additional chance for life it may give him, and the physician who deprives him of that right is at least negligent. We will never save all the phthisis cases that can be saved until we get rid of the idea that "specific medication" is a possibility, and concentrate our attention on improving the

patient's general and local vigor and nutrition.

Dr. Mays: I think that the principal reason why the pneumatic cabinet has fallen into disuse is because it cannot be used in private offices. In hospitals it can be used and is used.

In regard to the use of compressed air I would say that I made no reference to acute diseases when I cautioned against its indiscriminate employment; but thought of subacute or chronic pulmonary affections. I have in mind now a case of catarrhal phthisis of about eighteen months' standing, which I am quite sure became aggravated after the third inhalation of compressed air. She became worse in every respect, and died about two months later. I have knowledge of other cases who were served somewhat in the same way, and I seriously think that great care should be exercised until we know its influence on each case.

I certainly think that Dr. Cohen must be mistaken when he says that the effects of compressed air are the same as those of the rarefied air of mountains. Not to my recollection have I seen any one else express this view.

Selected Formulæ.

TREATMENT OF PIGMENTATION IN PREGNANT WOMEN.

In the *Journal de Médecine de Paris*, the following ointment is recommended to be rubbed into the affected parts twice daily, to remove the pigmentations which so often disfigure pregnant woman:

℞

Cocoa butter,	
Castor-oil	aa ʒ ij¼.
Oxide of zinc	gr. v.
Yellow oxide of mercury	gr. ij.
Essence of rose, enough to perfume.	

—*Therapeutic Gazette.*

THE CURE OF PERSISTENT DANDRUFF.

The following is recommended in the *Lancet* by Mr. Purnell for the relief of this troublesome affection: An ounce and a half of iron wine, one drachm of liquor arsenicalis, three drachms of syrup, water to two ounces. Of this one drachm is to be taken in water after meals. Then an ointment consisting of four drachms of the red oxide of mercury ointment, an ounce and a half of benzoated lard, and two minims of the essence of bergamot should be rubbed thoroughly into the roots of the hair, and its use continued for some time.

ON ICHTHYOL VARNISHES.

Unna undertook experiments with various substances in order to obtain an ichthyol varnish which was soluble in water and which would offer the advantages and none of the disadvantages of other ichthyol preparations. He recommends the following as the best:

℞

Ichthyol	40 parts.
Starch	40 "
Sol. of albumin	ca. 1–1½ "

The starch is to be evenly mixed with the water, then the ichthyol is to be well rubbed up in it, and lastly the albumin is to be added.

He also advises another varnish containing carbolic acid, but as this latter would precipitate the albumin, the formula is a little different:

℞

Ichthyol	25 parts.
Carbolic acid	2½ "
Starch	50 "
Water	22½ "

The ichthyol and carbolic acid are to be dissolved in the water by means of heat and the starch is then added to the solution.

Both of these varnishes dry rapidly and completely, do not dissolve under the influence of sweating, and can be easily washed off. They are applicable for the treatment of various circumscribed cutaneous diseases, and are recommended for acne, rosacea seborrhoica, rosacea simplex after frost-bite, and especially in lupus erythematosus. Also in certain forms of eczema, in intertrigo, in his tubercular eczema (a large pustular eczema occurring especially about the natural openings of the face, associated with tubercular glands and occurring in children, generally described as of a strumous type—Elliot), and again in erysipelas.

To the ichthyol varnish chrysarobin (2 to 5 per cent.) can be added, or pyrogallol, resorcin, sulphur, etc., and consequently it becomes useful in the treatment of all parasitic eczemas, of psoriosis, or of other cutaneous diseases presenting circumscribed lesions and patches. He suggests that when a new drug is added to the varnish an equal amount of water or of some oil, preferably linseed oil, should likewise be mixed with it so as to facilitate its incorporation and to preserve the thick-fluid consistency of the preparation.—*Jour. Cutan. and Genito-urin. Dis.*

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

EDWARD T. REICHERT, M. D.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF PENNA.,
EDITOR AND MANAGER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

THE MEDICAL AND SURGICAL REPORTER.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent 3 months on trial for $1.

At the termination of the period of subscription, we will promptly discontinue sending THE REPORTER unless directed to the contrary by the subscriber.

Remittances should be made by draft, check, postal note, or money order payable to Edward T. Reichert.

THE POCKET RECORD AND VISITING LIST.

Two sizes. Prices to subscribers of THE REPORTER: For 30 patients a week (with or without dates), $1.00. For 60 patients a week (without dates), . . $1.25. Prices to non-subscribers, $1.25 and $1.50 respectively.

THE MODEL LEDGER.

Physicians who keep their own books will find this of great value. Sample pages sent on application. Price, $5.00.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If THE REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS.

Write in ink.

Write on one side of paper only.

Write on foolscap or legalcap paper.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be pleased to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

LEADING ARTICLE.

MODIFICATION OF INFECTIOUS INFLUENCES BY MICRO-ORGANISMAL ANTAGONISM.

In a leading article published in THE REPORTER, (May 9, 1891,) the writer indicated a four-fold possibility of influencing infections, by the utilization, first, of the products of bacteria, which in a number of instances have been found to possess an inhibitive power over further development of the organisms from whose activities they have originated; second, of the antagonistic relations of certain bacteria toward other micro-organisms; third, of the antibacterial influence of various substances included under the general term, drugs; and finally, of those extraneous conditions which act unfavorably to the development of disease germs. The first of these was incidentally considered in relation to the recent attempt of Prof. Koch to overcome the tubercular infection; and sufficient was said to suggest the scope of its possible utility.

In a somewhat less, but nevertheless existing, degree of importance, the second of these considerations may be regarded; especially as there is no little evidence from laboratory sources that such an antagonism clearly exists between many growths. Moreover most of those micro-organisms whose influence is sufficient in contaminated cultures of pathogenic bacteria to destroy, or retard the growth of the latter, are as a rule saprophytes, nonpathogenic so far as the human economy is concerned. In what manner this antagonism is productive of its visible results is not understood; although it may be conjectured that two factors enter into the case, the simple effect of crowding and exhaustion of the elements necessary to life by the more actively vegetating growth, and the elaboration of the latter of some material deleterious to the existence of the other species. It is of interest in this connection to recall as an illustration the suspected influence exerted against tetanus by the suppurative micro-organisms.

It is a well-known feature of tetanus that the affection is peculiarly liable to develop in deep punctured wounds, such as are not apt because of the relative absence of oxygen to permit any marked growth of the pyogenic micro-organisms; while on the other hand in case of open, freely suppurating sores exposed to similar circumstances of infection, as in the feet of horses, the disease is not nearly so apt to manifest itself. Such a fact may be readily explained by the supposition that where free growth is accorded to the pyogenic bacteria there is formed some matter which exercises distinct retarding influence upon the tetanus micro-organisms, or that the full development of the former prevents by actual space encroachment the advance of the latter. The fact that suppuration is in a slight degree, at least, present in these deep, narrow wounds from which tetanus originates, does not militate against the supposition, since by the exhaustion by the pyogens of the limited amount of oxygen derived from the air supply a favorable circumstance is afforded the tetanus bacilli, which are essentially non-ærobic, the suppurative bacteria, however, being unable, from want of free ingress of air, to advance to any proportion sufficient to act against the tetanus germs. In the same connection it is to be recalled that Garré, several years ago, called attention to the fact that in tube cultures Flügge's fluorescent bacillus was persistently and fully antagonistic to the growth of typhoid bacilli and the pneumobacillus, and exercised a retarding influence upon the cholera spirilla. So too Pawlowski has come to the conclusion that the cure of anthrax is possible by bacterio-therapeutic means, this end being attainable by the subcutaneous injections of various micro-organisms at the point of entrance of the anthrax bacilli into the economy, the antagonistic germs employed by this investigator being Friedländer's diplococcus of pneumonia, the staphylococcus aureus, the bacillus prodigiosus, and the streptococcus of erysipelas. In connection with the last micro-organism the results of Pawlowski have been fully corroborated by von Emerich and Mattei. It is relevant, too, to recall, as mentioned by Garré, the rapid disappearance of the cholera germs from the effluvia in the presence of the saprophytes which are abundantly found. The researches of Pasteur, in relation to anthrax and fowl-cholera, and those of Heer upon typhoid fever and the yeasts and thrush and diphtheria bear upon the question in point. The numerous attempts toward the cure of malignant tissue growths by inoculation of such germs as the streptococcus of erysipelas are to be mentioned in this same category; although as an illustration these endeavors have little force from the very conflicting reports of results and from the fact that such growths are not even probably proved to be the products of micro-organismal activities.

The ultimate importance of this, as of any other medical subject, centres in its possible value in the management of disease. Herein at present, however, its demonstration practically fails. Under natural conditions the coincidence of infections in the economy has not been sufficiently studied in relation to the heightening or lowering of the consequent symptoms and little inference can be drawn until further attention is attracted to this feature. It is interesting, however, to cite here the observations of Woodward in relation to the affection to which the term "typho-malarial fever" has been applied, a type of disease in which from the statistics collected by the writer named from the records of the civil war the mortality is three or four times less than in the uncomplicated type of typhoid fever. Of course, this illustration, too, is open to the very grave objection that the affection named is not surely proved to be a combination of the malarial and typhoid infections; but in its clinical course it presents such a combination of symptoms, that, until it is shown to be independent of the combined pathogenic influences, it cannot well be overlooked. Within the recent experience of the writer there occurred in a child an attack of croupous pneumonia of the apex of the right lung, during the course of which a mild attack of varicella appeared; there was the usual

severity of symptoms of the pneumonia except in the case of the mental disturbance which although usually pronounced in such cases in this was of exceedingly mild character, and the disease ended by lysis. The varicella was insignificant, and it was particularly noted that it exercised no exaggerating influence upon the already existing pneumonic process.

It is true that there is nothing irrefutable, nothing decisive in these citations; but thus grouped they give some support to a theory which seems quite plausible and opparently only awaits the discovery of the surely existing proof. As to its therapeutic limitations, could the establishment of the principle upon sound clinical and experimental grounds be fixed, a field of the greatest importance opens. There can scarcely be imagined within human power so ready a means of modifying the severity of epidemics or the eradication of the malignant infections than by the introduction into the midst of the infected population an influence of infectious character having antagonistic tendency toward the primary disease cause. In their treatment, too, of the individual case there must be conceded an advantage if the promise of the subject be in any degree fulfilled. At the most the idea is but a step removed from the practice of vaccination in small-pox, in which case a virus, modified in intensity by passage through the bovine economy, grants immunity from and reduces the severity of already established infections of variola; possibly many of those who are disposed to regard vaccinia as a disease entirely separate from small-pox may look upon its results as illustrative of the applicability of the antagonism existing between micro-organisms.

Correspondence.

"ARSENITE OF COPPER IN DIARRHŒA."

EDITOR OF THE MEDICAL AND SURGICAL REPORTER.

Sir:—Allow me to correct a statement in the last issue of THE REPORTER which is calculated to create a wrong impression. In referring to the employment of arsenite of copper in diarrhœa, page 792, you have quoted Dr. Hintz, from a French journal, and suggest that he took his idea from my work in bringing this remedy to the attention of the profession. It is due Dr. A. F. Hintz, of Idalia, Colorado, to state that his paper appeared originally in the issue of the *Therapeutic Gazette* for February, 1891, and that in his communication, he mentioned the fact that he had first learned of the value of the drug from a communication which I published as early as 1888; he also referred to other papers of mine on the same topic.

Very Respectfully,
JOHN AULDE, M. D.
4719 Frankford Ave., June 20, 1891.

Book Reviews.

THE POCKET MATERIA MEDICA AND THERAPEUTICS. A resumé of the action and doses of all official and non-official drugs now in common use. By C. Henrie Leonard, A. M, M. D. The Illustrated Medical Journal Co., Detroit, Mich., 1891.

This volume is a pocket manual upon Materia Medica and Therapeutics, in which the author has incorporated all drugs of sufficient merit to warrant attention, whether official or otherwise, and includes remedies of as late introduction as 1891.

The general arrangement of the book embraces the pronunciation, genitive case ending, common name and dose, including the metric dose. *If a plant*, the part used, habitat, natural order, and description of plant and flowers, with its alkaloids, if any. *If a mineral*, its chemical symbol, atonic weight, looks, taste, where found, and its peculiarities. The action and uses of the drug, its antagonists, incompatibles, synergists and antidotes. Officinal and non-officinal preparations, with their medium and maximum doses, based so far as possible upon the U. S. Dispensatory.

Typographically, the book appears to be free from serious error, for which fact the publishers and author are to be congratulated.

Altogether, it is a handy manual for the student, physician or druggist, and it can be safely recommended as the most complete small book issued on this subject,

A COMPEND OF GYNÆCOLOGY. By HENRY MORRIS, M. D., late Demonstrator of Obstetrics and Diseases of Women and Children in the Jefferson Medical College, Philada., Etc., With forty-five illustrations.

These recent additions to the literature of a department of medicine so rapidly widening its bounds each year, should rather be termed a *digest* than a "quiz-compend," for it is not arranged in questions and answers, but gives a concise epitome of each subject treated. The author has been fortunate in the selection of excellent illustrations, and some features of his book are especially worthy of notice, including his original cuts. The chapter on gynæcological examinations is admirably suited to both student and practitioner, and the writer has succeeded in incorporating many very practical points. The portion of the work devoted to diseases of women, combines the latest ideas with an arrangement commendable for its exactness. A good feature also is the diagram of the proper positions of operator, assistants, nurses, instruments, etc., during ovariotomy. The description of this operation is well-timed and well systematized. In reading any book we naturally find things to hope for, but in reviewing this one the praise-worthy features entirely overshadow any defects it may contain, and the author has amply accomplished his object, in producing a book of use alike to beginner and busy practitioner.

PERISCOPE.

THERAPEUTICS.

ANTIPYRESIS BY DRINKING LARGE QUANTITIES OF COLD WATER.

Although he is a warm advocate of the bath treatment, Prof. Cantani regards slight reductions of temperatures as preferable in many cases to the marked antipyresis produced by a cold bath. During many years he has obtained this result by letting the patient drink large quantities of cold water, and administering, at least twice daily, a large enema of some cold slightly antiseptic solution. The same method of antipyresis is not equally efficient in all cases of fever; in typhus, for example, the most marked reductions of temperature are obtained by the drinking of large amounts of cold water, whilst in typhoid, cold enteroclysms yield better results. In typhus the patient is given from five to six quarts, and sometimes even eight quarts of cold water during the twenty-four hours, and the windows of the room are kept open day and night. In some of the cases the duration of the disease was markedly shortened, the temperature in one case being reduced from 41° to 37° on the eighth day. In typhoid fever large quantities of cold water are introduced into the bowel, and the effect of these is supplemented by letting the patient drink as much as possible of cold water. It was found by a large number of observations that after each enteroclysm of two quarts of water the temperature fell 0.5°–0.8– C. in the axilla, and this reduction was maintained for two, three or more hours. The water injected, which had a temperature of 11°, was usually evacuated in ten to thirty minutes, and then had acquired a temperatue of 35°–37° C.

Both of the above mentioned methods of antipyresis increase the quantity of urine and diminished its specific gravity, especially the drinking of water. This proves that the cold water is absorded in large quantities and then cools the entire body and even the blood, an effect more certainly obtained than with other hydro-therapeutic methods. Thus the internal organs which have the highest temperature during fever are cooled, the tissues are permeated and cleaned by the water and freed of ptomaines, and this takes place without disturbances of any kind, except occasionally a slight chill.

In ileo-typhus, the author has used for many years enteroclysms of two quarts of cold water (11°–12° C.) containing three, six or ten grammes of tannic acid and ten to fifty centigrammes of crystallized carbolic acid, and usually also one to two grammes of hydrchlorate of quinine. These are repeated twice daily, and their effect is sometimes astonishing. They prevent meteorism, or when it is already present, they cause it to disappear after two or three applications. The intestinal symptoms are reduced to a minimum, and the fever reduced and its duration shortened. In typhoid fever, if enteroclysis is employed at the commencement, it is possible in the majority of cases to abort the disease.—*Centralblatt f. allgem. Pathologic und path. Anatomie,* February 1, 1891.

THE TREATMENF OF MALARIA.

Laveran finds that in the contest between the organism and the hematozoons, the leucocytes play an important *role.* It is a well-recognized fact that if an insoluble and finely-pulverized substance be injected into the blood of an animal, the leucocytes rapidly invade this powder and charge themselves with its elimination from the blood (Ponfick, Hoffman, Langerhaus).

The reseaches of Metchnikoff prove that the leucocytes not only invade inert powders and the bodies of microbes, but also, in a great number of cases, the living pathogenic microbes, and that this property, known as *phagocytosis*, plays a very important *role* in the evolution of infectious diseases and in the phenomenon of immunity. The cells of the splenic pulp and those of the endothelium, of the connective tissue, and of the pulmonary epithelium participate in this power. He has also concluded that the paroxysm of the fever persists during the life of these micsobes in the blood, ceasing only when the parasites become the prey of the phagocytes. Especially is this marked in relapsing and malarial fever. The resistance which the microbes exert against this action of the leucocytes may be of long duration if they be lodged in the spleen or in the marrow of bone.

Wyssokowitsch has noticed that the spores of the *bacillus subtilis* lodged in the spleen were still living at the end of three months, an interesting fact in a point of view of the study of latent microbism.

Metchnikoff, Golgi Gamaleia, and others insist upon the destructive action of heat upon the microbes, while, on the contrary, cold diminishes the activity of the phagocytes. It is well known that an organism placed in the best general condition will resist most successfully the inroads of the pathogenic microbes, whilst all debilitating causes militate against the cure of malaria. Laveran himself has observed in animals whose blood contained hæmatozoa, that under the influence of an abundant alimentation the microbes disappeared, while dilatation favored their development. The anæmic diseases— over-fatigue, ill nourishment—are attended with frequent relapses of the fever, and the salts of quinine themselves seem to become powerless in preventing these relapses. On the contrary, under the influence of only a good regimen and rest, frequently the condition of malarial patients will ameliorate, the anæmia grow less, the relapses less frequent, and a cure may occur without the intervention of a more active medication, simply because the organism has been placed in the best hygienic condition.

All the tonics have, consequenty, a favorable action upon the progress of the disease, and foremost among these may be placed wine, coffee, and arsenious acid. Arsenic taken in small doses is of great service in the treatment of rebellious fevers with the malarial cachexia. If given in large doses, however, relapses of fever will often be produced, and the condition of the patient aggravated. Hydrotherapy is valuable, always used as a tonic medication. It succeeds sometimes when other medications have failed. It is well to know, however, that the first treatment may provoke a relapse ; hence it is necessary to proceed with prudence, beginning with short and lukewarm douches before arriving at cold douches, not touching at first the spleen, and prescribing some doses of quinine at the same time. One can readily understand that a cold douche, especially if applied over the splenic region or following a paroxysm, will cause contraction of the splenic vessels, driving the hæmatozoa into the circulation. The malarial patients who in thermal stations—Vichy, for instance—take these waters both internally and in the form ot baths, often have relapses at the beginning of the treatment, when they do not proceed with prudence. The change of climate is often beneficial to these patients, because the great heat of malarial climates is very debilitating, giving rise to exhausting sweats, nights without rest, and dyspepsia—all of which are corrected in a better climate. Quinine is of invaluable service in the treatment of these fevers, especially acting as a specific in the chronic forms. It has a very powerful destructive action upon all microbes, especially upon the protozoa, to which group the hæmatozoa belong. These rapidly disappear from the blood of patients who are submitted to a course of quinine medication. The spherical bodies and the flagellate forms disappear first. The treatment must be continued for some time to insure entire destruction of the microbes. It is probable that the phagocytes invade more readily the hæmatozoa when they have been killed or benumbed by the salts of quinine, but that the activity of the phagocytes is not directly influenced by the quinine. *La Médicine Moderne*, February 19, 1891.

ACTION OF OPIUM AND MORPHINE ON THE BOWEL.

Spitzer has published (*Virchow's Archiv*, cxxiii, Heft 3, 1891) an experimental investigation of the action of opium and morphine on the intestinal canal. His experiments were carried out on frogs, rabbits, and men ; his objects were to increase our very defective knowledge of the action of opium on the intestine, and to determine whether, as is generally assumed, opium is superior to morphine as an anti-diarrhœic and anodyne in intestinal affections. In frogs the bowel

was exposed and kept moist with saline solution. Very small doses of watery extract of opium given subcutaneously sufficed to diminish the sensitiveness of the bowel to painful stimuli, while leaving intact the sensitiveness to stimuli which simply call forth peristalsis, the skin sensitiveness being also unaffected, and there being no general narcosis. In this condition the action of the opium may conceivably be exerted on the brain, or the spinal cord, or on nerve centres in the wall of the bowel. The author concludes it cannot be on the brain, as the same result is obtained with decapitated frogs; he also thinks it cannot be on the cord, as its functions are otherwise left intact. The action must, therefore, be on the bowel locally, and this opinion is supported by the fact that even smaller doses given *per os* have an equal effect. That opium acts locally as an anodyne on the intestinal canal, apart from its general action, he further proves by giving a frog strychnine, and then tying the bowel midway between the stomach and anus. Stimulation applied to either half of the bowel equally called forth tetanic convulsions, but when a solution of opium was injected into the lower half, its sensibility was found to be greatly lessened in comparison with the upper half. Spitzer holds that the opium does not paralyse the ends of the sensory nerve in the bowel, but sensory ganglia which, he assumes, lie in the course of the sensory nerves in the wall of the canal. These get an undue share of the opium as the alkaloids are excreted from the blood into the intestine, are absorbed into the blood again, and again excreted into the intestine, so that there is a constant circulation of them in the blood vessels of the intestinal wall. The motor ganglia are also probably affected in the same way as the sensory, but either not so powerfully, or the action is not so readily demonstrable. Larger doses are required to diminish peristalsis than to diminish sensibility in the bowel. The diminution of peristalsis may be due to paralysis of motor ganglia in the bowel, or to a stimulation of the inhibitory centres in the cord from which the splanchnic nerves arise. Paralysis of the sensory nerve terminations in the wall of the intestine does not occur, because after very large doses of morphine the peristaltic movements of the bowel become very marked, and experiments pointed to the conclusion that the diminution in peristalsis was very largely due to an action of the opium in paralysing the motor ganglia in the walls of the intestinal canal. Large doses caused great increase of bowel peristalsis before general spinal tetanus was induced. The anthor thinks this is due to paralysis of the spinal cord, and consequent paralysis of the inhibitory action exerted by the splanchnic nerves. In this condition, however, the sensitiveness of the intestine to painful stimuli is much diminished. Morphine has the same action in every way, and quantitatively the activity of the opium is proportional to the amount of morphine it contains. The other alkaloids of opium have very little action on the bowel. On rabbits observations were made after exposing the bowel while the animal lay in a warm bath of saline solution. Spitzer confirms the well known experiments of Nothnagel, in which he found that irritation of the bowel with sodium chloride is not nearly so effectual in increasing peristalsis after the administration of opium or morphine. If a portion of bowel be completely isolated and the same experiment repeated, then peristalsis is not interferred with; this result is regarded as proving that in this case the opium acts on the spinal cord, and diminishes the inhibitory action of the splanchnic nerves. Spitzer, however, points out that irritation of the bowel from without with sodium chloride scarcely corresponds to physiological peristalsis or increased peristalsis after purgatives or irritation from within of the mucous membrane, as the peristalsis takes place towards the pylorus, and is very inconstant in amount. He therefore irritated the bowel by injecting into it a 15 per cent. salt solution, colored with indigo-carmine. The rate at which this solution progressd down the intestine was observed in normal animals, and was found to be two or three times slower after opium or morphine, the peristalsis being also much more gentle and regular in the latter case. Even after complete isolation of a portion of the intestinal canal from its mesenteric nerves, opium greatly diminishes the peristalsis. Opium given subcutaneously acts exactly to the same extent, and no better, than morphine subcutaneously, its activity being proportional to the amount of morphine it contains. In healthy men opium by the mouth acts somewhat more powerfully on the bowel than when given subcutaneously. The reason probably, is that the morphine is only slowly abstracted from the opium, and thus acts gently along the whole length of the bowel; it is not so quickly absorbed as pure morphine is, and in consequence does not produce so marked a general action. In diarrhœa, opium *per os*

is the most powerful—more so than opium extract or morphine subcutaneously, or morphine by the mouth. In slight intestinal pain opium by the mouth is the best treatment, as we get the desired analgesia with small doses and without constitutional effect, the local action on the bowel being probably sufficient; in very severe pain hypodermic injection of morphine is most effectual. [The author does not discuss diminution of intestinal secretion as a factor in the astringent action of opium.]—*Brit. Med. Jour.*

A COMPARISON BETWEEN SALICIN AND THE SALICYLATE OF SODIUM.

Dr. Alexander Haig has recently read a paper before the Medical and Chirurgical Society of London on the comparative merits of these two drugs in the treatment of acute articular rheumatism. He bases his comparison on the relative power of the two drugs to excrete, or to stimulate the excretion of, uric acid. He has found that the salicylate of sodium has about thirteen times the excretory potency of the other drug, and he thinks he has seen that their power to interfere with the course of the disease has been approximately identical with their liberation of uric acid. His contention is that all those plans of treatment of acute rheumatism that have proved beneficial have been so in an exact proportion to their uric acid secerning power. According to Dr. Haig's reasoning, acute rheumatism is caused by the presence of uric acid, primarily, in the blood and that being driven thence by a high acidity, it is precipitated in the joints, and that this precipitation of the acid, together with the fact of the non-destruction of the acid furnish us with the most manageable theory as to the inflammatory processes and pyrexia of the malady. The rise of temperature adds to the acidity and the precipitation of acid in the joints is more complete than in gout. There may be other causes besides pyrexia that will increase the acidity, such as suppressed perspiration and chilling, tonsillitis and other local inflammations, and the ingestion of acids and acid-forming foods, all of which are predisposing causes for rheumatic attacks. He also holds that the high arterial tension at the end of an attack is an indication of an excessive proportion of uric acid in the blood, and that, therefore, any cause that increases the acidity at that time tends to bring on a reprecipitation of the acid and a relapse.—*Jour. Amer. Med. Assoc.*

OFFICIAL REPORT OF THE RESULTS OF KOCH'S TREATMENT.

The official report on the results of Koch's treatment in Prussian hospitals has been published in *Klinisches Jahrbuch*, in which it is stated that out of a total number of 1,061 patients treated for tuberculosis of internal organs 13 were cured, 194 improved, 171 substantially improved, 589 unimproved, and 46 died. In external tuberculosis (lupus, scrofula, tubercular joints, etc.) 708 cases were treated; of these 15 were cured, 237 improved, 148 substantially improved, 298 unimproved, and 9 died.

We must confess that this report, which seems to have been made in all candor, is not at all encouraging. Under our old methods of treatment we can obtain some cures and many improvements. The new method does not seem to have accomplished very much more.=*Atlanta Med. Surg. Jour.*

THE THERAPEUTIC VALUE OF VINEGAR

In speaking of the therapeutic value of vinegar, Dr. S. J. Bumstead, of Decatur, Ill., says:

"I trust that a sneer will not curl the lip of him who first glances at the title of this article. But I must admit that the remedy is dreadfully common-place for these days of advanced therapeutics, yet if the reader will but control his prejudice for a few moments, while I point out a few uses for this remedy to be found in every household, I am sure he will become a convert to my good opinion of it, if he will only give it a trial.

"From time immemorial, vinegar has been used as a domestic remedy for colds and sore throats, usually with molasses or honey, and when there is almost a laryngitis with nearly constant tickling, it serves the purpose admirably, checking the tickling cough, and promoting resolution of the tracheal and pharyngeal inflammation.

"But its greatest value, in my opinion, is in cases of catarrhal croup, membranous croup and diphtheritic croup. Here I use it in the form of steam vapor, and although I usually give what I consider as suitable internal medication at the same time, were I coufined to the use of but one alone, I think I would in most instances choose the vinegar vapor. The most convenient method of administering it is by placing the vinegar—if not too strong, using it undiluted—in an ordinary bread-pan, to be found in every house. Then, by heating flat-irons or bricks in the stove and placing them in this pan, a great cloud of steam is generated. In this way the whole

room can soon be filled and the little sufferer draws it into his larynx and bronchial tubes with every breath he takes.

"The only difficulty I find in its use is to impress the nurses with the importance of maintaining the steam constantly. There is a disposition on the part of the attendants to keep up the steaming in a half-hearted manner. Of course, this steam is irritating to the bronohi of those who are well, but they can stand it during an emergency. With a severe case of membranous croup I have maintained the steam in the room to such a degree that it would be impossible to distinguish a person across the room. The advantage of this method of treatment over the use of any spray with an atomizer is that its operation is uninterrupted. I have seen a number of desperate cases of croup yield to this treatment, after tracheotomy seemed to present the only hope. So firmly convinced am I of its great value that I believe intubation and tracheotomy would only occasionally be necessary if it is faithfully carried out.

"A few years ago I noticed in one of our medical journals a report of some French physycians upon the virtues of acetic acid. They claimed for it germicidal properties about equal in value to that of carbolic acid. A word to the unprejudiced physician is sufficient."—*North Amer. Press.*

CAMPHORIC ACID.

Dr. H. A. Hare, writes: A man, aged thirty-five, was brought into the Hosital in the early part of January suffering from advanced phthisis with a large cavity at the left apex and with numerous smaller cavities in both lungs. There was a good deal of expectoration of purulent matter and a loose, racking cough, rapidly progressing emaciation, with that peculiar flattening of the wrist, which we so often see, so that the forearms looked like laths, and with such persistent and aggravated night-sweats that the occurrence of each sweat could be seen to increase very makedly his debility and asthenia. So severe was the effect of the sweats that I could always tell on entering the ward whether he had one the night before, and on one or two occasions I was shocked to notice what terrible changes had taken place during the past twenty-four hours. All the anti-sodorific remedies which I could think of were employed, without any avail or with only a slight decrease in the quantity of the sweat. Finally, in despair, I turned to camphoric acid and ordered that twenty grains of the drug should be administered,stirred up in a little milk or placed upon the tongue and washed down with water one hour before the time at which the sweat generally came on, namely, at one o'clock in the morning. To make a long story short, I can only add that during the remaining four weeks the drug absolutely controlled all sweating, although it was only given once in every twenty-four or torty-eight hours—thereby greatly increasing the patient's comfort and undoubtedly prolonged his life. It is also worthy of remark that this drug did not seem to decrease the other secretions, such as the saliva, or to cause the uncomfortable drying of the throat and feverishness of the skin so characteristic of full doses of belladonna.

The second case was that of a woman, aged twenty-five, suffering from pulmonary phthisis sf a more chronic form than that of the case which, I just detailed. In this case also the sweats were very annoying, producing insomnia and loss of strength, although they did not seem to be productive of as much debility as in the case of the man. In this instance. also, camphoric acid in the dose of twenty grains produced a most pleasing effect, completely controlling the sweating. I may also add that I have employed the drug in cases of nervous exhaustion and general debility accompanied with excessive sweating, with considerable success.

When we consider that the dose of twenty grains of camphoric acid is only a third of what may be given in cases where this dose fails, namely, sixty grains, it becomes evident that tne drug requires a more general trial by the profession, and that it will probably take a prominent place in the list of our materia medica. It is absolutely devoid of taste, insoluble in water, and comes in small micaceous crystals, which are soluble in alcohol. It does not produce the gastric irritation and burning produced by camphor, and in none of the cases in which I have employed it has it ever occasioned any distress or untoward symptoms.—*Med. News.*

ARISTOL IN DISEASES OF THE EYE.

Dr. James Wallace, in the *Univ. Med. Magazine*, writes: This drug has been for some time before the medical profession as an application to wounds, ulcers and other conditions in wnich iodoform has proved of value. In its physical characteristics it is superior to iodoform by its greater lightness and finer state of pulverization. In its application to the eye these qualities are of

much importance, as the mechanical irritation of small particles not sufficiently pulverized often exceeds the alterative effect which we wish to obtain. Apart from this, aristol seems to excite much less irritation than iodoform, even when finely powdered, and can be used with much greater freedom without exciting as much reactlon. The faint odor which it possesses is another point greatly in its favor, especially when used around the face.

The class of cases in which it shows its effects most markedly comprises follicular inflammation of conjunctiva, phlyctenular disease of the cornea and conjunctiva, marginal blepharitis, ulcers and after-enucleation of the eye-ball as a desiccant. In epithelioma of the eyelids, in my experience, it lessens the discharge from the ulcerating surface, but exerts no further action on the progress of the disease. In a case of lachrymal abscess, resulting in a large, sloughing ulcer, one centimetre in diameter, one week's treatment by aristol sufficod to close it entirely. In a case of enucleation of the eye-ball occurring in the practice of my colleague, Dr. de Schweinitz, aristol was dusted in the socket immediately after the operation ; on opening the lids on the second day no discharge was visible, the aristol had collected in a little heap around the conjunctival opening, and on lifting this out, the centre of the aristol was found to be quite dry.

The rapidity with which phlyctenular diseases yield to its application is very satisfactory, and as its use causes very slight irritation, there is no pain attached to its employment. The largest field for its employment is probably here. As we often desire some preparation of iodine to be exhibited internally we avoid the risk of using calomel, which is free from odor, but is liable to produce sloughing of the conjunctiva when dusted into the eye while the patient is taking an iodide, and the unpleasant odor of iodoform, which is intolerable to many persons, by employing aristol, which agrees with iodine compounds and is free from any noticeable odor.

In papillary trachoma it seemed only to aggravate the symptoms, and no beneficial results appeared to follow its use, but, on the contrary, the photophobia, lachrymation and corneal opacities increased ; this appeared to me to be due to the withholding of the proper treatment more than to any positively injurious influence of the aristol. In follicular trachoma its effect is very decided.

MEDICINE.

DISEASE OF THE CAUDA EQUINA.

Bechterew has recently met with a case in which he has diagnosed affection of the conus medullaris and the cauda equina. An abstract is given in the *Neurologisches Centralblatt*, No. 5, 1891. For some weeks before the patient came under observation he had suffered from a gradually increasing weakness in the legs, together with urinary trouble and weakness. On examination there was loss of sensibility with regard to tactile and also to painful impressions on the penis, scrotum, perineum, and gluteal region. There was also similar impairment on the inner and posterior aspects of the thighs. There was much muscular weakness, so that the patient could not walk without the help of a stick. The knee-jerk was normal, and of the superficial reflexes none were lost with the exception of the gluteal. There were incontinence of urine and obstinate constipation, although at times there was involuntary defecation. There was marked tenderness over the sacrum. The author concludes that the case is one of lesion of the conus medullaris and cauda equina, and draws attention to the correspondence of the clinical symptoms with those produced experimentally in dogs by section of the cauda equina.—*Lancet.*

ARSENICAL NEURITIS.

A good deal of attention has lately been given in America to the frequency of poisoning by arsenic, and it has been pointed out that a very much larger number of cases of this kind occur than is generally supposed. Among children especially, it is contended, the proportion of sufferers in this connection is considerable, wall papers colored with arsenical paints being the source of the poison in their cases as bearing on this matter. A remarkable statement was made at a recent meeting of the Boston Society for Medical Improvement by Dr. Putnam, who said that as the result of his own observations, he found traces of arsenic in thirty per cent. of the urines which he had examined with a view to ascertaining whether or not it was present in them. Eighty different samples were tested, and none of the patients exhibited any typical symptoms of poisoning by arsenic. The conclusion, of course, is, that a very large proportion of the general public, inasmuch as all are more or less exposed at some time or other to arsenical emanations, is un-

consciously infected. The occurrence of peripheral neuritis and paralysis as a result of this form of poisoning is established by the narration of a considerable number of instances in which it has been observed, and during the discussion referred to above, several such histories were detailed. Dr. F. C. Shattock described four cases of the kind as coming within his own experience, one of them being a choreic young woman who had been treated with large doses of arsenic, and in whom extensive arsenical neuritis and paralysis resulted. Another of these cases was that of a woman who had been supposed to suffer from rheumatism for years, but as Dr. Shattock suspected it might be due to arsenical poison, he examined the urine with the result that it was found to be largely impregnated with the metal. Testimony of a similar kind was offered by other observers, and there seems to be a very general opinion that the conclusions are fully justified facts. Dr. Putnam arrives at the following deductions in this connection:—(1) That chronic arsenic poisoning is manifested under four or five distinct forms, accordingly as the mucous membranes, the skin, the nerves, or the blood become primarily affected by the poison. (2) That one member of a household may alone be subject to the influence of the poison, others in the same dwelling remaing coincidently unaffected by it. (3) That symptoms may long outlast exposure. (4) That susceptibility to minute doses of the drug may follow poisoning. (5) That children, as a rule, can endure comparatively large quantities of arsenic, and that neuritis, though less frequent in them, does occasionally occur. (6) That elimination of the poison takes place less rapidly than has been commonly assumed.—*Med. Press.*

GRAVES'S DISEASE.

Dr. Hingston Fox read a paper before the West Kent Medico-Chirurgical Society on Graves's disease, especially with reference to cardiac condition. After speaking of the four cardinal symptoms, rapid heart, tremor, goitre and exophthalmos, any one or two of which may be absent in an undeveloped case, he dwelt on the mental condition found in severe cases. The emotional centers seem to be in unstable equilibrium, disturbed by slight influences, a condition allied to hysteria and to the effects of chronic alcoholism in woman about the climacteric. Muscular weakness and impaired nutrition, with neuralgia and the well-known eye symptoms were noted. Severe gastric crises had attended one case, the patient nearly dying from the vomiting, diarrhœa, etc., which appeared to be the effects of "bowel hurry." Dr. H. W. G. Mackenzie's theory of the pathology of the disease was adopted, the symptom being regarded as an expression of a permanent condition of the emotional nervous centers, set up in the first instance by terror or fright. Darwin's graphic description of the effects of sudden fear upon animals was alluded to, the thyroid enlargement being the only important symptom of Graves's disease which is there unrepresented. The fright may have been sudden, or a repetition of small shocks. Instances were quoted in illustration of this. This theory brings us, of course, only one step nearer to the true pathology, as regards the heart, beyond a hæmic murmur and eventually dilatation, there is not usually any sign of disorder except the rapid and irregular action. Some cases show tachycardia, others mainly irregularity; in some the condition is continuous, in others paroxysmal. The graphic record of one severe case in a lady, aged 49 years, was shown, extending over eight months. Here attacks of irregular and rapid heart action occurred at intervals of a few days or a week and lasting 24 hours or so. For treatment numerous remedies have been advocated. The author would lay stress on (1) moral and hygienic care in its widest sense; (2) improvement of nutrition, much milk, cod-liver oil, iron; (3) of drugs, belladonna in mild and early cases, iodides in later stages, pushed fearlessly to large doses, bromides in some cases; (4) locally the weak continuous current, following Dr. Samson in persevering long with its use, it should be applied to the thyroid with a large plate; Lister's cold coil also gives some promise; (5) for tracheal obstruction, tracheotomy, incision of capsule of tumour, or compression laterally in some cases, inhalation of chloroform, or lastly, division of the isthmus offers the best hope of relief.

SURGERY.

PROGRESS IN TRANSPLANTATION.

Dr. R. Haug, assistant at the Royal Surgical University-Policlinic of Munich, has published an "Experimental surgico-histological essay" in which he demonstates that the shell-membrane of a hen's egg is highly applicable to transplantation. On the strength of thorough experimental researches he makes the following statements:

The fresh shell-membrane of a hen's egg is perfectly capable of organization and therefore eminently fit for transplantation. It is only that side of the membrane which is turned towards the calcareous shell of the egg which can be used for the purpose of transplantation. It is not a mere agglutination that takes place in the case, though immigration of leucocytes from the neighboring tissues agglutination is gradually transformed into perfect assimilation. The intimate fusion of both tissues attains its climax in the appearance of an extensive vascularization. The latter causes the shell membrane to lose its specific properties and to be progressively transformed into conjunctive tissue. For this reason the membrane, as above stated, is eminently qualified to be used in all classes of granulating wounds, especially also for definite occlusion of tympanic canal.

A successful transplantation of a dog's skin on an extensive wound caused by burning has been performed by Dr. Alexander Miles, in England. This case presents a twofold interest; first, on account of the great frequency of such accidents, and then on account of the unusual therapeutic method made use of.

The left leg of a 10-year-old boy had been scalded up to the knee by accidental immersion in boiling hot, liquid cow food, and although he had succeeded in disengaging the leg immediately, it was found that the cutis had been loosened from the middle of the patella down to the articulation of the foot, the foot itself having been protected by the leather shoe. He was at first treated according to impirical methods and it was only after four weeks that a physician was called in. When the patient was admitted to the hospital, the whole lower part of the left leg was deprived of its cutis, with the exception of a small spot on the anterior side of the tibia, and the surface of ulceration was in a large proportion covered with healthy granulations, only a few necrotic fragments having remained attached between them. The latter yielded soon to the application of boracic acid compresses and after their gradual expulsion a fortnight later the whole surface of ulceration presented a healthy field of granulation, without any vestige of cicaterization. The enormous extent of the wound precluded all possibility of covering it with human skin and it was determined to use the skin of some animal. Miles selected a young, smooth-skinned dog for the operation. It was a week old and its color was black and white. After having killed it with chloroform, the whole ventral and crural portion of the skin was excised and a patch was formed consisting of the whole cutaneous tissue with the exception of the adipose layer. In the mean time the leg had been carefully cleaned and all blood had been removed from the granulations. The excised skin was divided into a number of strips, 4 inches long and ½ inch wide, and firmly pressed into the surface of ulceration, while smaller fragments of 1 square inch were used in filling up the gaps between the larger pieces. To a somewhat larger spot on the inside of the knee a piece of smooth skin from the tail of the animal was applied. Then, the whole was covered with a protective bandage, over which gauze imbibed with diluted boracic acid was added, and humidity was further maintained by a layer of gum tissue, over which finally a thick layer of sublimate-wadding and a firm bandage were applied. On the third day the bandage was renewed for the first time and, with the exception of a small fragment which was ulcerating and was removed, all other pieces were found to be firmly attached and the cicratization process beginning, as well at the edge of the large ulceration as in the center. The healing process progressed rapidly, although some particles of the large strips were ulcerating; all the smaller fragments were well attached. After 3 weeks the spots remaining bare were filled up with human skin (taken from a boy) and all were cicatrized in a short time. Six weeks after beginning of the treatment the ulceration was completely healed, but the patient was kept in bed for another fortnight and then he was allowed gradually to set the extremity in motion. When the boy was seen again, 7 months later, there was absolutely no contraction to be noticed in the cicatrice with the only exception of a very slight contraction where the caudal skin had been implanted. The color of the whole skin was uniform and very similar to the normal color, nor was there any hair or secretion to be seen; the sense of taction was not weaker than in the right leg and the temperature was the same.

In a case as the one related success depends principally on three elements: 1. The general condition of the patient; 2. the character of the process of ulceration; 3. the means employed for the purpose of accelerating the healing. In the case above stated the only favorable point in the general condition of the patient was his age. His general condition was very low the favorable result was mainly due to the method

of treatment. Although it could not be said that just a dog's skin is better approprial for transplantation than the skin of other animals, it presents at least the advantage of being always on hand and of furnishing a sufficient material for most cases. A most important element is the age of the dog. During the first days after birth the animal grows very rapidly and by transplanting a large portion of young tissue, endowed with an energetic growing force it becomes possible to cover rapidly the whole surface of ulcertion, this preventing contractions which always makes their appearance after extensive burnings, if they heal without artificial intervention.—*Deutsche Medizinal Zeitung.*

CATHETERISMUS POSTERIOR.

Under this title Dr. Goldmann (*Beitr. z. klin. Chir.*, 1891, p. 460) gives an account of a case in which no instrument could be passed up the penis into the bladder, but in which, after a suprapubic opening had been made into the bladder, a catheter was passed down into the perineum from the bladder and the stricture excised, with an excellent result. The man had suffered some years previously from gonorrhœa, and though he had had trouble with his stricture from time to time, had not suffered from permanent stoppage until some few months before he came under Dr. Goldmann's care. Another surgeon had performed suprapubic puncture, and so relieved for a time the urgent symptoms, but a severe cystitis ensued after a while, causing great pain both in the perineum and in the lower part of the abdomen, as well as some erysipelatous kind of swelling of the lower abdominal wall. Under these circumstances, as soon as he came into Hospital a fairly stiff elastic catheter was introduced through the abdominal puncture, which was by this time large enough to admit the little finger. It was, after some little trouble, manipulated along the prostatic urethra as far as the stricture, and another instrument was passed down along the urethra to meet it. The intervening stricture was then excised, and the cut ends of the urethra united by catgut. The swelling above the pubes speedily disappeared, and in about three weeks the patient was able to leave the Hospital. The plan, as the author remarks, is no new one, but instances in which it is applicable are but few. The manoeuvre in somewhat aided by pulling on the penis, and if possible hooking up the anterior wall of the bladder, as by this means the prostatic openingof the urethra is rendered more funnel-shaped, and is consequently more easily traversed by the catheter. References are given to some analogous cases, together with a full account of the different conditions to which this method is applicable, as well as the reasons which render it more likely to be attended with success now than formerly.—*Brit. Med. Jour.*

A MODIFIED SUTURE FOR INTESTINAL ANASTOMOSIS.

Sachs (*Centralblatt für Chir.*, No. 39, 1890, p. 737,) after referring to the various methods now in use, explains his modification of Senn's bone-plate method. Instead of two plates he uses one piece of bone, which he compares to a cuff-button with a hole through it. It more nearly resembles a pully wheel.

At the desired place for anastomosis the lateral surfaces of the intestinal loops are approximated by suturing serous membrane to serous membrane. A longitudinal incision is then made into each section of gut parallel to the line of suture. The bone button is then slipped in so that the line of suture with the two internal incised edges fits in the groove. The outside edges will fall into place in the other side of the groove, and a few stitches approximating serous surfaces will be found sufficient to retain the parts firmly.

The advantages claimed for this method are:

1. The intestinal lumen is not kept open long.
2. The line of incision is protected from infection by the internal ring—which also prevents closing of the incision.
3. Compression of the intestinal edges is prevented.
4. The sutures do not penetrate the whole thickness of the intestine.

The author has only used this method upon guinea-pigs. The buttons are made of decalcified beef-bone.—*Amer. Jour. Med. Science.*

GYNÆCOLOGY.

WHAT DISEASES SHOULD BE NOTIFIED AS PUERPERAL FEVER?

There can be no doubt that considerable difficulty is often experienced in deciding whether a particular case of *post-partum* illness should or should not be regarded as "puerperal fever," and notified as such to the sanitary authority. Most practitioners would rather not call an illness "puerperal fever" if they can conscientiously believe that another name is appropriate to it. On

the other hand, if they omit to report as such a case which some one else, believed by the friends to possess superior knowledge, thinks should be given that name, they lay themselves open to the charge either of incompetence or lack of frankness.

One of the conditions of a system of popular government like ours is that legislation must be in accordance with the general feeling and opinion of the time. If in advance of the time it is sure to fail in its object. In sanitary legislation the medical theories acted on must be those generally accepted; they must be in harmony with the views, not of the most recent investigators, but of the great bulk of doctors, old and young, town and country, English, Scotch, and Irish. A law based on theories not yet accepted by the bulk of those on whose judgment the carrying out of the law depends would raise an amount of opposition and misunderstanding that would go far to make it an absolute failure.

We imagine that some such reasons as the above influenced those by whose advice the term "puerperal fever" was inserted into the "Notification of Infectious Diseases Act" (1889). Just as "continued fever" was a sufficient diagnosis before typhus and typhoid fever had been differentiated, so until the last twenty years, or even more recently, more was known of puerperal fever than that it was a severe febrile disease affecting lying-in-women. Even now no other definition can be given to it. It used to be thought that all such cases were essentially alike, although they might differ in detail. One distinguished American obstetrician, we believe, still holds the view that there is a specific febrile disease affecting lying-in-women and no other persons. It was thought that puerperal fever was often epidemic. Such views as these were acted on by the late Dr. Farr, when the term "metria" was introduced as the equivalent of puerperal fever, and we presume this is the view tacitly accepted in the Act we have referred to.

The object of the Act is to enable, in the interest of the public, such precautions to be taken as shall prevent infectious disease being communicated by a patient to other persons; and abundant experience has shown that in most of the diseases named in the Act prompt action in isolation, disinfection, etc., is successful in doing this. In others the mode of propagation is so far obscure that the inquiries which notification may set going must be productive of increase in our knowledge, and therefore our power of prevention. No similar statements can be made about any of the diseases comprehended under the vague term "puerperal fever." They are not epidemic. This was proved in the most conclusive way by the late Dr. Matthews Duncan. The pupils of that eminent man can remember how, with grim humor, he used to say that when a great lady died in her confinement all the doctors said there was an epidemic; but if a poor woman in the Edinburgh Cowgate died after delivery no one thought of an epidemic then. "Puerperal fever" includes septicæmia, septic intoxication (the sapræmia of Matthews Duncan), pyæmia, phlegmonous inflammation of cellular tissue (the "erysipelas malignum internum" of Virchow), wound diphtheria or gangrene, as well as the less formidable conditions of endometritis, cellulitis, perimetritis, and fever from slight transient causes. All these are wound diseases; they are spread by want of cleanliness. If isolation be required it is isolation of those attendant on the patient, not of the patient. Cases must be very exceptional in which any good can come of the interference of the local sanitary officer; and in the few instances—likely to become fewer and fewer—in which investigation might do good public attention would be certain to be drawn to the matter, even were there no notification. Every argument for reporting deaths after childbirth applies equally to cases of febrile illness following surgical operations.

It is unfortunate that so vague a term as "puerperal fever" should have been thus legally stereotyped. But as it is so, it appears to us that the best way in which medical men can act harmoniously together for the public good—and no profession has ever been more ready to sacrifice its private interests for the public benefit—is in every case of febrile illness after delivery, not clearly arising from some cause quite independent of the process of labor, either to report the case or else to consult the medical officer of health for the district to ascertain from him in what class of cases he hopes for good results from their notification to him and to act in accordance with his advice. There is now abundant proof that such cases are very rare in the experience of those who carefully observe antiseptic precautions in their practice, and if now and then a doctor, by styling a case puerperal fever, for which he might have found a less formidable appellation, should incur the undeserved censure of some hastily-judging persons, his doing so will increase for him

the respect of others, who will understand and appreciate his desire to be perfectly candid with those who trust him and to do his duty to the public.—*British Med. Journal*, May 23, 1891.

ENDO-UTERINE THERAPEUTICS.

Dr. More Madden recently read a paper on this subject before the *Roy. Acad. Med. Ireland.* With regard to the methods of modern uterine treatment and the conditions by which this is called for, the author's observations are founded on a clinical experience extending over many years, and embracing upwards of 10,000 gynæcological cases treated in his wards or in the extern department of the Mater Misericordiæ Hospital, Dublin. Of the cases admitted into those wards during the last fifteen years, endo-uterine treatment was found necessary in 35 per cent. The two essential points in all such treatment are, first, that the orifice and cavity of the uterus, if not already suffiently dilated, should be mechanically expanded; and, secondly, that whatever application is resorted to should be brought into direct contact with the diseased endometrium. For the first purpose the slow, painful, and hazardous methods of dilatation by sponge or laminaria tents have been long abandoned by Dr. More Madden, who emyloys in their stead, the rapid cervical dilator which Messrs. Arnold have brought out in accordance with his suggestion, and which he finds more effective and quicker in its action than Hegar's or other similar dilators. The second object is especially necessary as a preliminary to endo-uterine treatment in cases of congestive hypertrophy and chronic subinvolution, in which the lining membrane of the uterus is commonly overlaid by an impervious pseudo-membranous albuminoid neoplasm evolved from the proliferating cilia of the diseased surface. Or else the endometrium, in many cases, is so thickly bathed in the tenacious morbid secretion therefrom, as effectually to protect the underlining tissues from the action of any remedial agent introduced into the uterine cavity until that pseudo-membrane and secretion are removed by the curette. For these objects Dr. More Madden recommends, first, the use of Duke's cervical curette to cleanse out the entrance to the womb; and, secondly, the employment of his own adjustable uterine curette, by which the endometrium may be thoroughly denuded, and at the same time by the hæmorrhagic discharge thus occasioned the congestion of the hyperæmic and hypertrophied organ may be most effectually relieved. In the treatment of subinvolution the author advocates the introduction, in some instances, of a small tampon saturated in a combination of tannic acid and turpentine, which he terms "tannoterebinth." This acts as an immediate stimulant and astringent on the uterine structures, and in suitable cases is allowed to remain in the cavity from twelve to twenty-four hours, unless sooner expelled from the then generally much contracted uterus. The vaginal glycerine saturated tampon commonly employed in cases of this kind, although unquestionably serviceable in many instances is messy and troublesome in its use both to patient and practitioner, and hence for some time past Dr. Madden has generally adopted the boric acid, or "dry treatment," recommended recently by Dr. Duke, and which he has found generally satisfactory as a substitute for the older method of treatment. He also strongly deprecates the employment of the ordinary syphon syringe for any endo-uterine purpose, and believes that this should be replaced by an irrigator such as the one he suggested many years ago, and which, having been since appropriated by others, without any acknowledgment, is depicted in the paper of which this is an abstract. The foregoing measures must, however, be supplemented by more active agents in those more serious cases of long standing, fundal, or corporeal endometritis and subinvolution in which the disintegrated and endo-uterine mucous membrane becomes the seat of various pathological changes, extending to the submucous structures and uticular glands, and often associated with those so-called fungosities resembling papillary epithelioma, which, if unchecked, may ultimately degenerate into that condition. In such cases it is that the cautery, actual or potential—the first in the form of igni-puncture, and the latter in the shape of the stronger caustics, acid, nitrate of mercury, fuming nitric acid, or chromic acid, etc.—may be justifiably resorted to in endo-uterine treatment. In conclusion, Dr. More Madden briefly details the result of his clinical experience of these various applications, the circumstances that indicate their use, the dangers that may attend their abuse, and the methods of their employment.

OBSTETRICS.

AN IMPROVED METHOD OF MANAGING THE CORD IN PROLAPSED FUNIS.

On the 3rd of March, 1890, Dr. L. T. Emery was called to attend Mrs. G. in confinement. His patient was of medium size, well nourished and a fairly vigorous woman, thirty-two years of age. She had been attended in her previous labors by Dr. Bodkin, of Brooklyn, and all three were described as having been difficult and requiring instrumental delivery.

Upon examination the cervix was found to be well dilated and the bag of waters intact (though rupturing very soon); the funis was prolapsed to quite an extent, and the head presented at and was partially engaged in the superior strait, the position being right occipito-anterior.

The pelvis was narrow—a condition most frequently existing where this accident occurs—and seemed to prevent delivery except with instrumental aid.

The patient was placed in a knee-chest position, which was somewhat exaggerated by the tilting of the mattress, preparatory to returning the cord by Prof. Thomas' method. In attaching the sponge—which had been thoroughly cleansed in boiling water—to the cord, Dr. Emery made use of the following device: A tape, one inch wide and twenty inches long, was bifurcated at each end about eight inches. Three-quarters of an inch from the point of bifurcation of one end, a button-hole slit was made in the broad part of the tape, leaving, something over two inches of broad tape intact.

The sponge was secured by tying the bifurcated ends nearest the button-hole around it, and then drawing one of these through the button-hole and again tying. The bifurcated ends of that part of the tape farthest from the button-hole were then passed around the prolapsed funis, and one end was thrust through the button-hole and the two ends tied securely and further tied around the sponge.

It is claimed for this method that the broad bearing of the tape lessens the danger of destroying the circulation between the mother and child, and that the sponge is held closely adjacent to the cord without constricting the latter nor nor slipping from either.

Passing a looy of the narrow part of the tape into the eye of a gum elastic catheter and securing by means of the stylet, and pressing forward or upward, with the catheter in my left hand and aiding and guiding the sponge with my right, the cord was passed one side of the sacral prominence, beyond the head of the child and into the uterine cavity.

Still keeping the patient in the same position he proceeded to apply the forceps. This was accomplished by reversing the procedure usual when the patient lies in a dorsal position, though still preserving the relative position of the forceps to the head of the child and the pelvis of the patient, the upper blade being passed into position first and the lower blade last. Traction was then made and the head engaged in the superior strait, when the patient was laid on her side and the delivery accomplished of a living child as in a case of ordinary forceps application.

The uterus was douched with a solution of biniodide of mercury, and the mother recovered without the occurrence of fever or any other untoward event, as the result of the treatment she had received.

CHLOROFORM IN OBSTETRICS.

Dr. J. F. Baldwin of Columbus, Ohio, in a paper read before the Ohio State Medical Society, entered a plea for the more frequent use of chloroform in obstetrics.

His obstetrical triad is as follows:

During the first stage of labor, morphia.

During the second stage of labor, chloroform.

During the third stage of labor, nothing.

Summary.—Chloroform relieves pain.

It shortens labor, usually.

It prevents shock.

It prevents nervous and physical exhaustion.

It reduces the liability to rupture of cervix and perineum.

It does not conduce, in any material degree, to post partum hæmorrhage.

It does not affect the fœtus.

It is absolutely safe when properly administered.

Contraindications.—1. Such conditions of labor as lead the obstetrician to believe that he may, at some supreme moment, require all the woman's voluntary efforts to assist him. Such conditions are very rare. 2. Fatty degeneration of the heart; though, if we accept the conclusions of the Hyderabad Commission, even this may not be a contraindication; and the disease is practically never diagnosed except post mortem.—*Memph. Med. Month.*

CASE OF SUDDEN AND UNEXPECTED DELIVERY IN THE ERECT POSTURE.

There being only a limited number of cases of sudden and unexpected delivery in the erect posture on record the following case is perhaps worthy of mention:

S. D., aged 21, who had previously, after a lingering labor, given birth to one child, was recently visiting a friend, when she felt a sensation of giddiness. She therefore left and started on her way home. Having walked fifty yards a sudden pain in the abdomen was experienced; the pain was so acute that she retired to a neighboring outhouse. She had no sooner arrived there than she gave birth to a full term male child. The child fell head foremost on to the stone floor. The fall was broken by the cord, the cord was ruptured, and no hæmorrhage occurred; the child sustained no injury, not even a bruise being apparent, and is still alive (two months after the occurrence). The mother walked back to to her friend's house, and has made a good recovery.

There had been a miscalculation of two months in this case of the probable date of parturition, and the mother had no idea of the cause of the pain until the child fell from her.

Dr. E. Hugh Snell, in *Brit. Med. Jour.*

GIANT FŒTUS; CÆSAREAN SECTION.

Dr. R. Neumer (*Centralbl. f. Gynäk.*, April 25th, 1891) describes a case where a woman, aged 40, bore a giant fœtus. She had already given birth to eleven children, and it appeared that labor occurred a month after term. The abdomen was unusually large, and as the labor made no progress turning was attempted. The child was found to be of enormous size, and could not be extracted, its pelvis sticking fast in the maternal pelvis. An attempt to disarticulate the leg, as a preliminary to evisceration, failed, as the hip could not be reached. The mother being in a critical condition, Cæsarean section was performed, but she sank shortly after the extraction of the child, The child (together with the blood which it had lost in great quantity through the attempt at amputation, so that it was almost bloodless when extracted) weighed nearly 24 pounds.—*Brit. Med. Jour.*

THE TEMPERATURE AFTER LABOR AND SO-CALLED LATE INFECTION.

Stapfer (*L' Union Medicale*, Aug. 2 and 14, 1890) believes that the most valuable index of a woman's condition in childbed is the daily morning and evening record of the temperature. He has noted that a temperature persisting slightly above normal, with a trifling evening rise, is often the precursor of the so-called late infection. A temperature of 100° or 101° may be present on the evening of the first day due to the fatigue of labor; forty-eight hours later, as the result of the milk secretion. At any time before the fifth day it may occur from fæcal intoxication, when the bowels have not been evacuated. This elevation, however, is transient. It is the persistence of a slight elevation to which he calls especial attention, and he believes that in such cases the absorbed poison may be so attenuated as to produce no other symptom for a variable length of time. In one of his cases very slight fever, continuing during three weeks, was the only morbid phenomenon of septic infection.

He believes that the thermometer can predict the occcurrence of so-called infection, such as pelvic inflammation and abscess, phlegmasia, pulmonary and visceral thromboses, cutaneous eruptions, which may occur from the seventh or twelfth day to the fifth or sixth week. When any of these complications are to occur, the temperature ranges between 99° and 101° up to the time of their occurrence, with, perhaps, an occasional temporary fall to normal. Many patients are discharged with this amount of fever unnoticed, who later return to hospital with one of the above complications fully developed. He cites several such cases, and believes it demonstrated that the poison (streptoccus pyrogenes) is either encysted and localized, or spreads by the blood giving rise to complications whose nature and gravity depend upon the number and virulence of the microbe and its secretions and the receptivity of the soil. He is convinced that in such cases the three weeks of apparent apyrexia is a veritable period of incubation, revealable by the thermometer, whose value, therefore, is exceedingly great in conditions apparently normal and physiological. In a case with intestinal paresis and considerable distension, severe pain in iliac fossa and over the uterus, anorexia and disappearance of milk secretion, he predicted that the patient was not septic and gave a favorable, and afterward justified prognostic, because the temperature during a week had remained between 97.7° and 99.1°.

Barbers will soon be compelled to use antiseptic precautions.

PÆDIATRICS.

CLOUSTON—THE NEUROSES OF DEVELOPMENT.

Traumatism is assigned by most authors as a cause for idiocy and congenital imbecility. Parents are prone to look for some accident as to the cause for such conditions, resolutely shutting their eyes to manifest hereditary weakness. While the author makes allowance for such sources of error, he believes that there are left certain cases where traumatism must be assigned as the exciting cause of the arrest of brain develpment. This is intelligible enough when there is a gross lesion of the brain, as a clot causing pressure. It is not as clear, but still must be accepted as a fact, that sometimes a fall or a blow is followed by a change in the development of certain brain functions. Traumatic idiocy is in such cases not as marked either in mental impairment or in physical expression.

Rickets, night-terrors, the febrile delirium of children at temperatures ranging from 99° to 101°, infantile eclampsia, and the hysterical affections of childhood are all classed by the author as neuroses incidental to childhood from birth to seven years. They all occur in children of neurotic heredity far more frequently than in other children. They are referable to weakness of inhibitory function and instability in the brain cortex at an era when the organ is rapidly growing and the convolutions are deepening and expanding in even greater proportion than the rest of the brain. Rickets is clearly a trophic neurosis probably due to want of sunlight sufficient to give stimulus to the central trophic nervous centres which innervate the bones and perhaps other tissues. But these exciting causes of want of light and bad city conditions of life will not, as a rule, produce rickets in the children of healthy, country-born parents. That the brain cortex is affected is evident from their common neurotic accompaniments, retardation of growth, and a tendency to precocious and unhealthy mental advancement which stops short of full mental growth.

The author agrees with Jenner and Henoch in attributing the so-called convulsions of teething far more to rickets than to dentition. The first motor sign of the instability of any brain is a tendency to convulsions during the first dentition. Many cases of developmental epilepsy will be found to have had convulsions during dentition. The same kind of unstable brain will become delirious at night even with very low febrile temperatures. Such children will take convulsions at slight attacks of indigestion.

Night-terrors, the author believes, is an affection that is really psychical, and may be considered equivalent to a convulsion occurring in the menta areas during sleep.—*Edinburgh Medical Journal*, March, April, May, 1891.

INFANTILE SPLENIC ANÆMIA .

The following are Somma's conclusions :

1. Infantile splenic anæmia, or splenic pseudo-leukæmia is a common disease of childhood, more common than has usually beed supposed. Its origin may date from the very beginning of life.

2. Its introduction into modern pathology is largely due to the investigations of Cardarelli and Luigi Somma.

3. It is characterized by the well-known form of progressive gravè anæmia, associated with chronic hypertrophy of the spleen which, with its special characters, has no relation with other morbid conditions.

4. Clinically it is manifested by a complex train of pathognomonic and accidental phenomena. The first or necessary ones are unfailing in every nosographic form of the disease, the second may be present but are not always clearly distinguishable.

5. In its circle of evolution three periods are usually to be observed, being periods of beginning, development, and cachexia.

6. There are three principal forms of the disease, the chronic febrile form, the chronic afebrile form, and the chronic form with recurring attacks of fever.

7. The true nature of the process is not yet clearly understood, but from such investigations as have been made it is supposed to be due to a micro-organism which is introduced into the system and finds its medium of development within the spleen. Having passed into the circulation of this organ, it determines the many anatomical and functional changes in the organ which mark the clinical phenomena of the disease.

8. It has a chronic cause which varies from eight months to three years, and there are also cases which continue when adult life has been reached.

9. The disease may terminate in three ways,—in death, which is the most frequent way; in a prolonged chronic state, which continues into adult life; and in complete cure.

10. The prognosis should be a most guarded one, and one should aim chiefly to

to modify the symptoms. The propriety of splenectomy is not yet decided upon. Such a grave operation is of course to be avoided if possible.

NUCLEATED RED BLOOD-CORPUSCLES IN THE ANÆMIA OF CHILDREN.

Dr. John Loos, of the Pædiatric Clinic of Prof. Escheric. in Graz, reports as follows to the *Wien. Klin. Wochenschr.* No. 2. 1891. The author found the nucleated red corpuscle in thirty-one cases during life. The cases were for the most part of children under two years of age, only four ranging between two and thirteen years. In one instance it was a child with trismus; in another a boy of five years afflicted with pulmonary tuberculosis (the only case of tuberculosis in which this corpuscle was found.) Five other cases were children suffering from chlorosis, syphilis, or purpura. A great majority of the cases presented a symptomatology which clearly corresponded to the splenic anæmia of Henoch and the infantile pseudo-leucæmic anæmia of Jaksch. The children are extremely pale, their skins glossy, but they are fairly nourished. The peripheral lymph nodes of the axilla, the neck, the inguinal region are greatly enlarged; and the internal glands are enlarged and soft, not indurated. A splenic tumor was universally present. The bones were rachitic. In addition to the nucleated corpuscles, the blood contained a diminished amount of coloring matter, a reduction of the amount of hæmaglobin, and more or less pronounced leucocytosis.

The character and the etiology of the disease are as yet obscure. The prognosis is absolutely unfavoroble. A reduction of the spleen-tumor, as described by Henoch, was not observed in any of Loos' cases. The children, when they did not succumb to the anæmia itself, fell a ready prey to such intercurrent diseases as pneumonia.

HYGIENE.

EPIDEMIC RELATIONS OF DIPHTHERIA IN NORWAY.

Axel Johannessen, of Christiania, reviews the various epidemics of diphtheria which have occurred in Norway, and makes some remarks upon diphtheria and croup. He concludes that the largest part of cases of croup which occur both before and after the great epidemics of diphtheria are of diphtheretic natnre.

An interesting point is developed regarding the mode of invasion of the disease and the parts of the country affected. These, in different epidemics, have been to a certain extent the same. Density of population and such means of conveyance as railways and streets do not appear to play any part in the spread of the disease. The coast districts have one-third more cases of diptheria than the inland districts, and the fishing districts of the coast are the most affected. At Dorschfang from 25,000 to 30,000 men collect in 5000 huts, being huddled together under bad hygienic conditions. At Tromsö-Stift diphtheria generally shows the highest number of cases of the disease—as many as 105 per thousand of population. Moreover, statistics also show that those districts whence the fishermen are sent out and return again are invaded by the disease in proportion to the number of fishermen, a condition which is true of other epidemic diseases, especially typhoid fever.

In Norway and Sweden the morbidity in the cities is, on the whole, greater than that of the country; but usually epidemics in cities develop more slowly, and rarely reach an excessive height; whereas, it is much more frequent for an epidemic in the country to rise rapidly to a high ratio between diseases and population. The mortality is absolutely greater in the cities; on the other hand, the percentage of dead of those medically treated in the country districts is considerably higher. This circumstance seems to be due to the fact that throat diphtheria is, in the country, more fatal than in the cities, where, on the other hand, a decidedly greater number of victims is furnished by diphtheria of the larynx.

The great variations in the disease curves are not primarily dependent upon meteorological influences.—*Deutsche med. Wochenschrift*, March 19, 1891.

BARBERS AND CONTAGIOUS DISEASES.

Antisepsis is now the law of the land in Germany, and it is not long since some violation of its rather changeable precepts was punished with imprisonment. The victim in that case was a midwife, but medical men have, we believe, been threatened with similar penalties. Barbers are, in some parts of Germany, subject to strict rules as to the disinfection of their razors, curling irons, etc. That enactments of this kind might with advantage be made general, not only in the Fatherland, but in other countries, is shown by a case recently reported to

the Berlin Dermatological Society by Dr. Oesterreicher. A man, aged 30, presented himself, with a papulo-squamous eruption, enlargement of the lymphatic glands in the neck and elsewhere, mucous patches on the soft palate and other secondary syphilitic lesions. The patient denied all knowledge of any primary infection, nor did the most minute examination of the genitals reveal any suspicious appearance. On the left side of the face, however, there was an area of cicatricial thickening exactly resembling a healed hard chancre; this, the man stated, was a result of a cut received some time before whilst in the hands of the barber. Dr. Oesterreicher had no doubt that the disease had been inoculated in that way. In 1884, Dr. Löbl, of Vienna, reported a number of cases in which sycosis, herpes tonsurans, and alopecia furfuracea, had been communicated by dirty razors and other implements of the hairdresser's *armamentarium*, and urged the desirability of making it compulsory for these artists always to disinfect their instruments before use.—*Brit. Med. Jour.*

THE IDENTIFICATION AND STAINING OF TUBERCLE BACILLI.

Mr. Baker, High Holborn, London, has had the happy idea of fitting out a small box with all the requisites for the prompt staining and identification of the tubercle bacillus. Although the collapse of Koch's treatment has lessened the interest which this particular microbe excited a few months since, it must always be a great assistance in the diagnosis of doubtful cases to be enabled to subject the sputum to bacteriological investigation. The box, which measures 8 by 6 by 4 inches, contains an adequate supply of fuchsin and methyl blue (the latter for counter staining), with acid solution for decolorising, and balsam for mounting purposes, in addition to a spirit lamp, watch and cover glasses, slides, etc. Full but simple and explicit directions are pasted on the inside of the lid which, in our hands, proved perfectly workable and satisfactory.—*Med. Press.*

MEDICAL CHEMISTRY.

ON THE PRESENCE OF URETHANE IN THE URINE IN BRIGHT'S DISEASE.

In examinations of large quantities of albuminous urine, Dr. Rademaker has always met with a crystalline organic compound that was soluble in water, ether, chloroform, alcohol, and benzol, and almost insoluble in petroleum ether. This organic compound differs from all the constituents of normal urine. This compound can be readily isolated by the following process: Evaporate several litres of albuminous urine to dryness on a water bath, and extract the residue with 98 per cent. alcohol and filter. Allow the alcoholic solution to evaporate at a low temperature. Treat the oily residue with dilute sulphuric acid and extract with ether; allow the ether to evaporate spontaneously. The residue contains urethane in an impure state. Dissolve the residue in distilled water, and filter from the oily matter. Treat the filtrate with carbonate of potash to an alkaline reaction and again extract with ether, the ether allowed to evaporate and the residue placed in an exsiccator over sulphuric acid, when gradually crystals in the form of plates separate. These crystals are dissolved in distilled water, and the solution treated with a solution of subacetate of lead, the excess of lead being removed with carbonate of soda and again extracted with ether. If now this ethereal solution is allowed to evaporate spontaneously, it leaves urethane in a pure state. If a solution of these crystals is boiled with NaOH, ammonia is evolved, showing the presence of nitrogen. If this alkaline solution is treated with an acid CO_2 is evolved.

ANALYSIS OF SUBSTANCE DRIED IN AN EXSICCATOR OVER SULPHURIC ACID.

0.1047 gram of substance gave 0.1537 of CO_2 and 0.0736 H_2O,

Which equals..... .....40.00 per cent. C.
and..... 7.83 " " H.
Nitrogen, by Kyeldahl's process.....14.90 " " N.
Urethane ($C_3H_7NO_2$).

Requires	*Found.*
C = 40 44 per cent.;	C = 40.00 per cent.
H = 7.86 " "	H = 7.83 " "
N = 15.70 " "	N = 14.90 " "

If a little of this substance was dissolved in distilled water, and the solution treated with a solution of carbonate of soda and a few scales of iodine and then heated, the smell of iodoform was produced. This solution, upon cooling, deposited crystals of iodoform. If part of the crystals are treated with solution of ammonia, heated in a closed tube, neutralized with dilute sulphuric acid, and then submitted to distillate gave a distinct reaction for alcohol, with the iodoform test and chromic acid reaction, which is explained by the following equation:

Urethane. Ammonia. Urea. Alcohol.
$C_3H_7NO_2 + NH_3 = CH_4N_2O + C_2H_5OH.$

These reactions, and the ultimate analysis

conclusively prove that this substance is identical with urethane.

As urethane is formed by the action of alcohol upon urea when heated (as the following equation will explain):

Urea. *Alcohol.* *Urethane* *Ammonia.*

$CH_4N_2O + C_2H_5OH = C_3H_7NO_2 + NH_3$

Dr. R. thought it best to treat normal urine the same way that he had treated the albuminous urine, but not a trace of urethane was formed; however, if the alcoholic extract of normal urine was evaporated at a high temperature, urethane was always formed.

Urethane is a powerful narcotic, and Dr. R. advances theory that to this substance the so-called "uræmic poisoning" in Bright's disease is due.—*American Pract. and News.*

News and Miscellany.

THE FIVE YEARS' CURRICULUM.

The difficulties which will occur to everyone as to the best means of utilizing the extended period of education of the medical student are strikingly shown in the report of the Committee of Management of the Examining Board in England which has just been issued, and which will come on for discussion at the next meetings of the respective authorities of the two colleges. The committees are generally agreed on the subjects of the curriculum, but differ as to the number of examinations which should be held during the five years of study. The six members have three different views as to this point, and so three schemes will be submitted to the two colleges for their decision. Under the first scheme, recommended by the medical representatives of the Committee of Management, there would be three examinations, as at present: the first, after six months' attendance at a medical school, would embrace chemistry and physics, pharmacy, elementary human anatomy and elementary biology; the second, at the expiration of the second winter session, would include anatomy and physiology; the final, after the expiration of three winter and three summer sessions from the date of the candidate passing the second examination, would deal with medicine, surgery, and midwifery. During this last period the student must have received clinical instruction in fevers and small-pox. The scheme practically alters but very little the present arrangement, except that elementary biology is added to the first examination, that courses of lectures on public health and therapeutics must also be attended, and that a special paper on forensic medicine, public health, and general therapeutics forms part of the examination. The second scheme, presented by two of the surgical representatives, is similar, so far as the first and second examinations are concerned, but the third examination is to be passed at the expiration of two years from the date of passing the second examination, and consists of medicine, surgery, and midwifery, as at present; but the latter subject may be taken at the fourth examination if the candidate elect to do so. Under this scheme the final year is to be devoted simply to an extra year's attendance at a Hospital (to include attendance at a fever Hospital) and a fourth or final examination in clinical medicine and surgery must then be passed. In the third scheme drawn up by the remaining surgical members of the committee the student is required to pass a series of annual examinations, the first in chemistry and physics, elementary human anatomy, and elementary biology; the second in anatomy, physiology, and elementary pathological anatomy; the third in anatomy, including histology, physiology, pathological anatomy, pharmacy, and elementary knowledge of drugs; the fourth in the principles of medicine and surgery and in pathology; whilst the fifth, or final, embraces the practice of medicine, the practice of surgery, the practice of midwifery and diseases of women, and the elements of forensic medicine and of public health. Doubtless there will be many differences of opinion as to the relative value of the schemes, but at present we would only point out that they all agree in introducing into the curriculum the subject of elementary biology; that ophthalmology, diseases of children, and mental diseases are unmentioned; that there is no provision made for spending the fifth year with a practitioner as a pupil, but the extra year practically becomes merely an additional year of ordinary Hospital study and hospital work, except that a certain unspecified time is to be given to fevers. We question if these arrangements are such as were anticipated by the General Medical Council when they passed the resolution insisting on this fifth year of medical education.—*Lancet.*

A TEN YEAR'S CURRICULUM.

The course of medical study at the Buddhists' Lama University, in Thibet, is ten years. The first four years are devoted to language and theology, the eighth year to astrology, and physiology succeeds only in the last two years.—*Ex.*

HARVARD MEDICAL SCHOOL FELLOWSHIPS.

Three scholarships of $5,000 each have been established through the gift of William S. Bullard.

The exhibition of bacteriological apparatus at the coming International Congress of Hygiene, promises to be exceptionably fine.

A HOSPITAL FOR INFECTIOUS DISEASES IN TURIN.

The King of Italy gave 160,000 lire ($32,000) on his last birthday to the city of Turin to assist in the erection of a hospital for contagious diseases.

Dr. James N. Martin has been appointed Professor of Obstetrics and Diseases of Women at the University of Michigan. He filled the chair since Prof. Dunster's death.

Crystallized Chloroform.—The Swiss physicist, Raoul Pictet, has discovered a method of preparing crystallized chloroform for commercial use. Kept in this form it cannot undergo any changes or contain any impurities.

PYOKTANIN STAINS REMOVABLE.

The blue stains on the hands, etc., from Pyoktanin, *are readily removable* by lathering with common soap (rubbing-in well,) and then washing (or, if need be, brushing) off with alcohol, or with *any strong* alcoholic liquor.—*Mercks Bulletin.*

MEDICAL DIPLOMAS IN KENTUCKY.

Resolved that the Secretary be instructed to place upon the list of medical colleges whose diplomas are to be certified and endorsed for registration under the laws of this State, only such colleges as shall, after the session of 1891–2, exact of matriculates and graduates a minimum of requirements not less than those required by the American Medical College Association.

THE ASSOCIATION OF GERMAN ALIENISTS

The Association of German Alienists will meet this year at Weimar, on September 18th and 19th. The following questions among others will be discussed: Responsibility and Criminality, Drunkenness in Relation to Responsibility, Prophylaxis of Tuberculosis in Lunatic Asylums, the Present Condition of the Aphasia Questions, Therapeutic Employment of Hypnosis in Lunatic Asylums, Care of Epileptics.

KOCH INSTITUTE IN BERLIN.

The clinical section of the new Institute will be completed within a few weeks. There are seven parlors, having accommodations for 108 patients, and two parlors for physicians and attendants. Prof. Ludwig Brieger, will probably be at the head of the clinical department, and Dr. Richard Pfleger will have charge of the scientific department. Koch, it is said, will receive a salary of 20,000 marks ($5,000,) and Drs. Brieger and Pfleger each 6,000 marks ($1,500.)

SOCIETY MEETINGS.

The American Association of Obstetricians and Gynecologists will hold its fourth annual meetiug, at the New York Academy of Medicine, 17 West Forty-third street, in the City of New York, Thursday, Friday, and Saturday, September 17, 18 and 19, 1891, under the presidency of Dr. Adam H. Wright, of Toronto. All physicians interested in the discusssion of subjects pertaining to Abdominal Surgery, Obstetrics, and Gynecology are invited to attend without further formal notice. By order of the Executive Council.

William Warren Potter, M. D.,
Secretary.

COMPARATIVE COST OF MEDICAL EDUCATION IN ENGLAND AND AMERICA.

According to the estimate of the Secretary of the Illinois Board of Health, the average fees for the eleven London schools are, exclusive of the examination fees, £118, 5s.; for the provincial schools. £98. In addition each student has to pay from 10s. to £3 matriculation to one of the degree-granting bodies; from £1 to £15 for 1st examination; from £1 to £10 for the 2d; from £2 to £15 for the first degree or qualification examination. In some of the colleges in the United Sates all the fees do not amount to $300, and in at least one the whole course of study and the diploma can be had for $138.

The first annual meeting of the U. S. Medical Practitioners' Protective Alliance was held at Baltimore, June 11th and 12th. The society was incorporated under the laws

of Maryland. Officers for the ensuing year were elected, and such other business transacted as was necessary to establish the Alliance on a basis of permanence. As usual in meetings for organization, comparatively little work could be done outside the regular routine in such cases. Addresses were delivered by the officers, and several papers on alliance work in general were read and discussed. The proceedings will be published in a few weeks.

THE BRITISH MEDICAL ASSOCIATION.

The fifty-ninth annual meeting of the Association will be held at Bournemouth on July 28th and three following days. The President-elect is Dr. J. R. Thomson, consulting physician to the Royal Victoria Hospital, Bournemouth. Addresses in Medicine, in Surgery, and in Public Medicine will be given by Dr. Lauder Brunton, by Dr. John Chiene, and by Dr. E. C. Seaton respectively. The scientific business will be conducted in nine sections, presided over by distinguished members of the profession. The exhibits at the animal museum will be arranged in five sections. At the dinner of the Metropolitan Counties Branch of the Association the treasurer of the Association, Mr. Butlin, expressed the hope that the annual meeting would be held in London in the year 1894.

CANADIAN MEDICAL CERTIFICATES.

The College of Physicians and Surgeons of the Province of Quebec has, with the earnest coöperation of the universities, been endeavoring to get its certificates recognized in Great Britain on the principle of reciprocity. The terms of the Act of 1886 require, however, that before foreign or colonial diplomas can be recognized in England they must be recognized in the country in which they are obtained. Qualifications gained in Quebec are only recognized in the province of Quebec. Canada herself in other provinces does not recognize the certificates of the province of Quebec. In great questions this partial application of legislation provincialises and belittles; and it will have to be modified if countries with strong central Governments are to recognize those where local restrictions prevail.

THE AMERICAN SOCIETY OF MICROSCOPISTS.

This association, now in the thirteenth year of its existence will hold its fourteenth annual meeting in Washington. D. C., August 10, and continue in session five days. Its roll of active members contains about three hundred and fifty names, embracing very nearly every person in the United States who is at all prominent as a microscopist. Its membership consists of two distinct classes, viz.: professional men and students of the natural sciences, who use the microscope in their daily avocations as an instrument of research, diagnosis, or precision; and amateurs, or those who find pleasure and profit in the revelations of the instrument. Many of the latter class, from having chosen special lines of study and investigation, have acquired high reputations in their respective departments of microscopical research. In its earlier years this class predominated in the membership of the society, but at present the professional element is largely in excess.

The qualifications for membership are very simple. The applicant must be a respectable person socially, and interested in the use of the microscope.

A MEDICAL TEMPERANCE CONGRESS.

The managers of the National Prohibition Park, of Staten Island, invite representative medical men from all localities in the United States and the Dominion of Canada to meet in conference on the 15th and 16th of July in the great Auditorium Building of the Park. The chief object of the meeting is to be the comparison of views on the relationship of physiology and alcohol. Among the questions to be discussed will be the following: "What are the Hereditary Effects of Drunkenness?" "Are there any Hereditary Effects that Follow Moderate Drinking?" "To what Diseases are Inebriates More Especially Exposed?" "Is Alcohol a Poison?" "Is Alcohol in any Sense a Food?" "What are the Proper Uses of Alcohol as a Medicine?" "Is there Danger of Producing the Drink Habit from the Prescribing of Alcoholic Medicines?" "How Large a Percentage of Deaths May be Attributed, Directly or Indirectly, to the Use of Strong Drink?" "Should Alcoholic Liquors Ever be Used Except Under the Direction of a Medical Adviser?" It is announced that, at this Conference, all views will be given an impartial hearing, and no restraint will be placed upon the discussion save that of the time limit.

HOW TO LOOSEN GLASS STOPPERS.

The *Pottery & Glassware Rep.* states that some one of the following methods is certain to prove effective:

1. Hold the bottle or decanter firmly in the hand or between the knees, and gently tap the stopper on alternate sides, using for the purpose a small piece of wood, and directing the strokes upward.

2. Plunge the neck of the vessel in hot water, taking care that the water is not hot enough to split the glass. If the stopper is still fixed, use the first method.

3. Pass a piece of lint around the neck of the bottle, which must be held fast while two persons draw the lint backwards and forwards.

4. Warm the neck of the vessel before the fire and when it is nearly hot the stopper can be removed.

5. Put a few drops of oil around the stopper where it enters the glass vessel which may then be warmed before the fire. Then apply process No. 1. If the stopper still continues immovable, repeat the above process until it gives way, which it is almost sure to do in the end.

6. Take a steel pin or needle and run it round the top of the stopper in the angle formed by it and the bottle.. Then hold the vessel in your left hand and give it a steady twist toward you with the right, and it will very soon be effectual. If this does not succeed, try process No. 5 which will be facilitated by it.

FOREIGN BODIES SWALLOWED BY A STOWAWAY.

On Thursday, May 21st, the body of an Arab, found dead on one of the ships in the Albert Dock, was taken to the Seamen's Hospital, name unknown. A necropsy was ordered by the coroner, and made by Dr. F. Croucher, house surgeon to the branch hospital. There were no signs of disease in the brain or the chest, except a few old adhesions in the left pleural cavity. The gall-bladder was very distended and full. Three small ulcers existed on the anterior coat of the stomach. Several patches of inflammation were found in the small intestine. In the cæcum were found twenty trousers buttons, three cog-wheels (apparently out of a watch, two of them 1 in. in diameter—these were doubled), one 2 in. steel screw bent double and one 1 in. screw, six pieces of a lock (the biggest piece was 1½ in. long and ½ in. broad), a circular piece of brass (1¾ in. in diameter folded into four), several pieces of iron wire (four were 1½ in. in length), brass, and lead, and two key tallies on a ring, one inch in length. In the ascending colon, about five inches from the cæcum, were found a piece of steel wire one-eighth of an inch in diameter, and three inches and half in length, bent double, and one small cog-wheel. The weight of these bodies together amounted almost exactly to half a pound. The body was much emaciated; no subcutaneous fat was present in chest or abdominal walls, or any fat round the kidneys. The deceased was quite unknown; no particulars could be discovered by the police employed to obtain evidence for the purpose of the inquest. There was no perforation of intestines, or any sign of disease in the colon.—*Lancet.*

A DUBLIN DOCTOR'S DOGGERELS.

This is a little book of rhymes, originally printed for private circulation, and now, as the author says "saved from the waste paper basket." It would have been a great pity if they had been consigned to that ignominious receptacle for they are irresistibly funny and marked by much cleverness, both of idea and of expression. The medical poems, or rather we should call them skits, are especially amusing. Here is a specimen:—

Should you suffer from lumbago,
Live on nothing else but sago,
Rub the lower part of spine
With the strongest turpentine,
Try the treatment used by quacks,
Drop on melting sealing wax.
If there still is no relief
Try a six-inch mustard leaf,
Take a needle and a syringe
Inject ether every twinge,
If there's no relief from pain
Try a Pulvermacher's chain.
Then rub smartly with sand paper,
It will make you dance and caper,
Then, while resting from your toil,
Smear the part with "Jacob's Oil."
If all fail, try belladonna,
It will cure you, 'pon my honor.

Here is another:—

Doctors wonder, and well they may,
How the profession can possibly pay,
Hundreds still will crowd the ranks,
Giving advice without fees or thanks.
Too many Hospitals, far too many,
Giving their help without charging a penny,

Hundreds who could afford a fee,
Get at a Dispensary treatment free.
The profession allows it, what's the use
Of alluding at all to such an abuse?
The struggling practitioners doing their duty,
While quacks and bone-setters live on the booty.

It is clear that a humorist and rhymer of the first water has been lost to the laughter-loving public in the Dublin doctor.—*Medical Press.*

THE INTER-CONTINENTAL AMERICAN MEDICAL CONGRESS.

OFFICE OF THE PERMANENT SECRETARY OF THE AMERICAN MEDICAL ASSOCIATION.

Philadelphia, Jnne 4th, 1891.

To the Medical Profession of the Western Hemisphere:

At the meeting of the American Medical Association, held at Washington, May 5th, 1891, Dr. Charles A. L. Reed, of Cincinnati, introduced the following:

Resolved, That the Ameriean Medical Association hereby extends a cordial invitation to the Medical Profession of the Western Hemisphere, to assemble in the United States in an Inter-Continental American Medical Congress.

Resolved, That the Committee on Nominations be and is hereby instructed to nominate one member for each State and Territory, and one each from the Army, Navy, and Marine Hospital Service, who shall constitute a committee, which is hereby instructed to effect a permanent organization of the proposed Inter-Continental American Medical Congress, and to determine the time and place at which the same shall be held.

The resolutions were seconded by Dr. Wm. H. Pancost and others, and unanimously adopted.

Pursuant to the foregoing the following Committee was nominated and elected:

Alabama—R. F. Saunders.
Arizona—Henry A. Hughes.
Arkansas—Ed. Bentley.
California—W. R. Cluness.
Colorado—Wm. A. Campbell.
Connecticut—C. A. Lindsley.
Delaware—C. H. Richards.
District of Columbia—D. W. Prentiss.
Florida—C. R. Oglesby.
Georgia—J. McFadden Gasten.
Idaho—Geo. P. Haley.
Illinois—N. S. Davis.
Indiana—A. M. Owen.
Iowa—B. H. Criley.
Kansas—J. E. Minney.
Kentucky—J. N. McCormack.
Louisiana—Stanford E. Chaille.
Maine—Hampton E. Hill,
Maryland—Geo. H. Rohe.
Massachusetts—Augustus P. Clarke.
Michigan—C. Henri Leonard.
Minnesota—P. H. Millard.
Mississippi—W. F. Kendell.
Missouri—I. N. Love.
Montana—Thos. J. Murray.
Nebraska—R. C. Moore.
Nevada—P. J. Aiken.
New Hampshire—Irving J. Watson.
New Jersey—E. J. Marsh.
New Mexico—C. E. Winslow.
New York—John Cronyn.
North Carolina—H. Longstreet Taylor.
North Dakota—E. M. Darrow.
Ohio—Charles A. L. Reed.
Oregon—Wm. Boys.
Pennsylvania—Wm. Pepper.
Rhode Island—Geo. L. Collins.
South Carolina—R. A. Kinloch.
South Dakota—J. W. Freeman.
Tennessee—J. R. Buist.
Texas—J. W. Carhart.
Utah—F. S. Bascom.
Vermont—H. H. Holton.
Virginia—J. S. Wellford.
Washington—J. M. Morgan.
West Virginia—J. H. Brownfield.
Wisconsin—J. T. Reeve.
Wyoming—J. H. Finfrock.
U. S. A.—
U. S. N.—A. L. Gihon.
U. S. M. H. S—J. B. Hamilton.

WM. T. BRIGGS, M. D., *President.*
WM. B. ATKINSON, M. D., *Per. Sec.*

THE INTER-CONTINENTAL AMERICAN MEDICAL CONGRESS.

OFFICE OF THE CHAIRMAN OF THE COMMITTEE ON PERMANENT ORGANIZATION.

Cincinnati, June 6th, 1891.

The Committee appointed by the American Medical Association to effect a permanent organization of the Inter-Continental American Medical Congress, met at "The Arlington," Washington, May 7, 1891. The following officers were elected: Charles A. L. Reed, M. D., Cincinnati, O., Chairman; J. W. Carhart, M. D., Lampasas, Texas, Secretary; I. N. Love, M. D., St. Louis, Mo., Treasurer.

On motion, the officers were appointed a special Committtee to draft a Constitution, and report the same at an adjourned meeting of the general Committee, to be held at St. Louis, Mo., Wednesday, October 14, 1891, when the time and place of meeting of the Congress will be decided, and permanent officers be elected.

CHARLES A. L. REED, M. D., *Chairman.*
J. W. CARHART, M. D., *Secretary.*

PROFESSOR ANGERER, of Munich, has been appointed Professor of Surgery in the University of that City, to succeed Nussbaum.

No. 1793. PHILADELPHIA, JULY 11, 1891. Vol. LXV.—No. 2.

Clinical Lecture.

CHRONIC NEPHRITIS.

BY JAMES M. ANDERS, M. D.,

PROF. OF HYGIENE AND CLINICAL MEDICINE AT THE MEDICO CHIRURGICAL COLLEGE OF PHILA.

Male, thirty-three years of age, single, employed in gas works, working near the fire, becoming heated and cooling off suddenly. This is one form of exposure and is to be remembered. Family history negative Three years ago he had typho-malarial fever. Soon after, he began to be troubled with rheumatism, affecting only the left knee, never migrating from one part to another. About six months ago the pain suddenly ceased and almost immediately the other leg began to swell, first at the knee, then above the knee, and later, from the knee down to the foot. One month ago he began to swell in the abdomen, as well. From the time he first noticed this œdema until now, he has felt as though—were it not for the dropsical effusion and symptoms of dyspepsia—he were perfectly well.

Notice that this man has a peculiar pallor of the skin, and if you were to feel of it, as I do, you would notice it is somewhat harsh. When you pinch up the skin of a person suffering from kidney trouble, especially chronic diffuse nephritis, you will find that when you allow it to fly back, it will do so only gradually as compared with normal skin ; in other words, the skin has lost some of its natural elasticity, besides becoming dry and harsh. Now, I told you that the man's heart was perfectly sound, so far as I could determine. His urine has been examined and found to contain considerable albumen and a few granular and epithelial casts ; specific gravity, 1,025. There is no history, such as we sometimes get, in cases of this kind, and such as you will frequently meet with, where a person is seized with a rigor, followed by swelling such as this, with perhaps vomiting, severe headache, or other well-marked nervous symptoms ; in short, all the symptoms of acute diffuse nephritis gradually merging into the chronic form of the disease. This accute form of Bright's disease is frequently caused by exposure. Where the trouble come on insidiously, as in this instance, you have chronic nephritis, so-called, from the beginning. The causes of this variety are syphilis, which this man denies ; alcoholism is also denied ; and gout or rheumatism, from which latter disease, however, he has suffered.

This brings me to discuss briefly the different forms of nephritis. The subject is in a state of great confusion, even among leading writers. What one describes as chronic parenchymatous, another will call chronic diffuse nephritis, and so on. Let us bear in mind that we have cases of nephritis in which only the epithelial lining of the tubes is affected ; these constitute acute and chronic parenchymatous nephritis. Where the disease is ushered in by chill, fever, and bloody urine with large amount of albumen and casts, you have to deal, as a rule, with acute diffuse nephritis. Additionally, we have the most common form of the disease, namely, chronic diffuse nephritis.

There is one element in this man's case which has not as yet been investigated. He has apparently a great deal of ascites. The man denies that he has ever been, even a steady alcohol drinker. We know that cirrhotic conditions of the liver frequently are associated with cases of chronic nephritis. We have, in this man's case, as you will recall, great œdema of one limb, not so much of the other, and great distension of the abdomen. Now, that being the case, the liver ought to be investigated to see whether it is in a state of cirrhosis. Cirrhosis, as you know, is usually divided into two stages, first, that of hyperplasia of connective tissue, causing enlargment, and, secondly, the stage of contraction, in which the organ undergoes

great diminution in size. The normal liver dullness extends above to the 4th interspace or 5th ribs; sometimes percussion resonance extends lower down, but this you must remember is on inspiration. To make a long story short, let us see if this man's liver is enlarged or diminished. We have on the surface one evidence of cirrhosis, namely, enlargement of the superficial abdominal veins. We begin above and find the ribs, 1st, 2d, 3d, 4th, 5th. On the man breathing out, we find that liver dullness begins at the 5th rib. Now, you may not get the lower line of dullness, where you have so much effusion as you have here, by keeping the patient on his back, but by getting him to turn on his left side, any fluid in the peritoneal sac will naturally gravitate toward the left side of the body and give me an opportunity of ascertaining how far down the liver dullness extends. By so doing you notice that below the costal border I get tympanitic percussion resonance, since no liquid is there now. I also get tympanitic percussion resonance one inch higher up than the costal border. We find that this man's liver has undergone considerable contraction. You may remember that I told you some time since that in cirrhosis of the liver in their subjects, we can sometimes feel the under surface of the organ by placing the palm of the hand over the chest, with the fingers extending down over the costal border, making deep palpation in the backward and upward direction. By this means, I say, you can sometimes feel the lower surface of the liver, which is roughened in cases of cirrhosis. I have not succeeded in doing so in this case.

Now the prognosis in a case of this kind, is not favorable. In all cases of kidney trouble, the tendency is for more and more of the kidney to become involved. Again in a great many cases, the outward evidences of renal disease do not bear an exact relation to the extent of the lesion. Sometimes a man will die of some intercurrent disease, and the kidneys will be found to be the seat of chronic nephritis. The wonder is, how such an one can go on so long without manifesting any evidence of kidney trouble. Of course, any intercurrent disease, in such cases, is very apt to prove fatal. So we will look upon the prognosis in this case as grave. As far as ultimate recovery is concerned, we cannot promise anything.

When you come to consider treatment, you want to bear certain facts in mind. First, that a great many of the symptoms and conditions that arise during the course of a chronic nephritis are not due to the kidney trouble at all. Of course, the majority of the graver symptoms are probably all ascribable to the kidney lesion. In the second place, what can we do for the kidney trouble itself? What can we do for the symptoms caused by the kidney trouble?

What can we do, in this case, for the actual lesion in the kidneys? Very little, I am sorry to say. We know that the albumen and casts are due to the kidney lesion, and we shall endeavor to diminish the amount of this substance in the urine, but I fear, only, if at all, temporarily. We will give tincture of the chloride of iron, and with a bichloride of mercury in small doses. This sometimes does diminish the amount of albumen and casts. The chloride of gold and sodium has in my hands sometimes proved quite useful, in these cases. It has perhaps a curative action on the lesion in the kidneys.

Then we must improve or remove those conditions due to the kidney trouble directly. Now of course most of the dropsy is due to the condition of the kidneys, but not all. Why? Because in a great many cases of nephritis, there are circulatory disturbances, or there are other troubles. Heart disease and kidney disease are frequently associated in the same person. We may have diseases leading to dropsy, independently of any renal trouble. We must then get rid of the dropsical effusion, which in the majority of cases, is due to the kidney lesion. Now with the kidneys in bad condition, we cannot as a rule, remove the fluid through that channel, so, besides using diuretics (I gave him ext. digitalis gr. $\frac{1}{8}$, arsenious acid gr. $\frac{1}{50}$ powdered squill gr. $\frac{1}{2}$, in pill, 3 times daily to improve the blood and as a gentle diuretic) you will remember I told you one of the leading objects is to produce free purgation, with a view of carrying off the liquid. You can do more good by means of purgatives than you can by means of diuretics in these cases, and, so far from increasing the patient's discomfort, you will greatly relieve him in this manner. You would not, of course, give large doses of the drastic purgatives when the patient is feeble.

I have prescribed for this patient, calomel, gr. v, jalap, gr. x, at bed time, and, by the way, that combination, though old as the hills, is one of the very best to remove effusions of this kind. As a result of the pill containing digitalis, arsenic and squill, and the powder given one week ago, the œdema is already somewhat less, especially in the region of the stomach. I want to throw out the thought here, that where the

heart's action is good and regular, as in this case, you are perfectly at liberty to prescribe hydragogue purgatives, and can do so much more safely than when the heart is not in good condition.

We will continue this treatment and endeavor additionally to limit the amount of casts and albumen by the iron and mercury mixture which I gave you.

I have another case of chronic nephritis, to show you; one that presents quite as many points of interest as the case you have just seen.

We meet with cases of organic heart trouble, frequently associated with chronic nephritis, and this may occur in three ways: 1, organic heart disease may lead to chronic nephritis; 2, we have a class of cases in which the heart disease follows the kidney lesion. Many cases that begin as acute diffuse nephritis and acute parenchymatous nephritis lead to a chronic form of nephritis, and you have coming on hypertrophy of the left ventricle, sometimes to a very marked degree; 3, we have a class of cases in which chronic nephritis and chronic valvular disease of the heart exist in the same person, but the one condition not necessarily dependent on the other.

In the case which has just gone out, you have chronic nephritis with a heart which is apparently normal; the left ventricle however, will certainly enlarge in a short time, as a result of the nephritis. In the present case we have lesions of the heart and kidney, one lesion, probably, independent of the other.

M. R; age forty-three; married; housekeeper all her life; gives a rather unsatisfactory family history. There is no distinct specific history obtainable; there is no alcoholic history in the family. We obtain, however, a feebly marked history of rheumatism; one of her brothers, a year ago, had rheumatism in this city. Her parents never were troubled with this disease, so that we get a comparatively negative family history. Her own previous history is not without interest. She had always been well until about nine years ago, when she had influenza. This was followed by a falling out of some of her hair; at the same time she had eye trouble, due probably to iritis. She was subsequently well until five or six years ago, when she was suddenly seized with œdema of the limbs, which soon included the entire body. When the œdema began she did not have rigors, followed by high fever, bloody and smoky urine and well marked nervous symptoms, but the œdema came on simply with some nervousness, some little nausea, and some headache. Headache she has been troubled with for some years past. Let us bear in mind a few facts pertaining to her primary attack to her bed; the attack lasted about three months, and under treatment the œdema all disappeared, not, however, permanently forever. Subsequently, during the last five or six years, she has had from time to time a little œdema of the feet; she also had well marked attacks of headache, always attended with a great deal of nausea and sometimes even vomiting. Now that is the history of a great many cases of chronic nephritis, the history of a great many cases of chronic diffuse nephritis, beginning with more or less marked subacute attack, without febrile symptoms, the evidences of the attack disappearing, followed by comparatively good health for a certain number of weeks, or even months. Even during that time, however, you would frequently find albumen and casts on examining the urine. During all these five years she went on in that way. In the fall of 1890 she contracted a heavy cold, which was followed by rapid swelling of the limbs. Suddenly, on the cold getting better, the œdema in great part disappeared. These attacks recurred many times during the following winter, and were attended with considerable cough and muco-purulent expectoration, dyspepsia, nausea and frequent severe headache. This is the history she gave a week ago. She also says that within the last month or two, the swelling has been permanent and has risen to the abdomen. Now, with this long history, remembering her condition when she presented herself, we can make a correct diagnosis, which is chronic diffuse nephritis. She has a mitral regurgitant murmur and a mitral stenotic murmur as well. She, in all probability, has some dilatation of the right side, a murmur with the first sound, over the ensiform cartilage, indicating tricuspid regurgitation. Remember that where you have organic disease of the heart, soon after compensation fails we have chronic congestion of the kidneys, which frequently leads to chronic diffuse nephritis, sometimes simply to chronic parenchymatous nephritis. The question, however, arises in this case, whether nephritis or valvular lesion from which she is also suffering, was the primary affection.

This woman's heart trouble may have been coming on for many years, without the knowledge of any one about her, until the compensation failed, and that may have been her trouble six years ago. On the other

hand, we do know too that there are cases of organic heart trouble such as we see here, associated with chronic nephritis such as we have here, the one not depending on the other, and that is one of the points I want to emphasize to-day. If we had had her under observation all these years, we could have determined which ailment came on first. Looking at the case from the present standpoint, we are probably only justified in saying that we have chronic valvular disease and chronic nephritis in the same individual, the one not necessarily causing the other. So these cases of chronic diffuse nephritis associated with chronic valvular trouble, are modified cases of nephritis and the treatment is different from that of the case which has just gone out. Here too, we must attack the lesion in the kidneys. We cannot do much for it directly; more can be done by improving the general health of the patient. Unfortunately, neither can we do very much for the organic heart lesions directly. We can, however, greatly modify the effect of the lesions in the heart by regulating its action, and by increasing the force of its contraction. That is what we have been trying to do in this case and we have in part succeeded. You remember I told you that when you have a good heart, free purgation is the best thing to push actively to reduce the dropsical swelling. In this case before you, however, instead of drastic purgatives, we have ordered small doses of elaterium gr. $\frac{1}{12}$ every two or three days, which will act on the bowels. I will give her Basham's mixture for its effect upon her kidneys. I have also given her something, not to modify the walls or valves of the heart directly, but simply to increase the force of its muscular contractions and to regulate its action. For that purpose I gave digitalis in combination with Basham's mixture. This meets several indications. Basham's mixture is more or less diuretic, as well as an astringent to the kidneys and is a good blood tonic, while the digitalis affects favorably the heart, and its diuretic action assists in getting rid of the effusion throughout the body.

Let us then continue this treatment which was begun four days ago, more especially since she comes back saying she is much relieved; indeed, her dyspnœa at the time of her first visit was frightful. To-day, she breathes very well, all because the heart's action has been regulated, diminished in frequency and the force of the contractions much increased. As in the case of this woman, there may be apparently imminent danger of death and yet within a week the patient may be perfectly comfortable, simply because circulation has been reestablished, the lungs have been relieved, and some effusion gotten rid of. In other words, what seemed a week ago to be a case of nephritis, far advanced, with danger of death, to-day is a patient comparatively comfortable, without any other symptoms than swelling, slight cough and dyspnœa on exertion.

NECROSIS OF TIBIA.—TREPHINING FOR EPILEPSY.

BY THOMAS H. MANLEY, M. D.

VISITING SURGEON TO HARLEM HOSPITAL, ETC.

Gentlemen: The first patient that I will show you to-day, is a female 34 years of age. Five years ago she knocked her left knee against a step and fell. Soon after this, she developed pain over theleft tibia, the parts becoming swollen, inflammed and markedly enlarged. At this time, she was operated upon for the relief of her trouble, but without any apparent success, and since that time, she has undergone four other operations at as many different hospitals in this city, but with the same result. She looks now, as you can see, pale, anæmic and exceedingly emaciated.

She has been suffering so much pain by reason of this trouble in her leg that she has been compelled to take large doses of morphine hypodermically for its relief. The patient has been sent to me, by her physician, for the purpose of having the leg amputated, close to the knee-joint, as she is suffering the most intense and constant pain and is every day becoming more and more emaciated.

Having secured the consent both of the patient and her physician to amputate, I shall be guided in that respect largely by the etiology of the trouble; whether it be due to sarcomatous, carcinomatous, tubercular or syphilitic causes. She gives us no history of any specific trouble whatever, and neither do the lymphatics or lungs show any evidences of tubercular infiltration, nor do I find any evidence of a sarcomatous or carcinomatious degeneration to account for this trouble in the tibia. So, having excluded all these etiological factors we are obliged to fall back on traumatism to come at the cause of this trouble. As a result of this traumatism, this woman first developed a periostitis, which was soon afterwards, followed by an osteomyelitis, with the destruc-

tion and subsequent removal of certain portions of dead bone. I have frequently seen an osteomyelitis develop from the use of strong antiseptic solutions on the denuded ends of living bone. A peculiar feature of this disease is that it will skip the articular structure of bones, without leaving any possible trace of its destructive action on the cartilaginous or other soft, overlying structures. I have frequently seen instances of this kind, so that when it cut down on the bone, have found it reduced to a pulp.

The question might be very naturally asked of me, Why not amputate in this case? With such a perfect knee and ankle action as we have here without the slightest impediment to muscular movement and complete integrity of the fibula, I do not deem it wise to sacrifice a limb without first making an effort to save it. What I propose to do here is to cut down on the diseased bone as far as the periosteum, and then carefully dissect the bone of this membrane and remove all the diseased osseous tissue that I shall find. There is one great precaution that I wish to emphasize in this connection and that is when I reach the bone, I shall avoid the use of any bichloride solution whatsoever, and guard carefully the overlying periosteum.

The patient was then placed under ether and the parts carefully washed and cleansed, first with soap and water, and afterwards with a bichloride solution of the strength of 1–5000. An Esmarchs bandage was then applied above the knee-joint and carried as far up as the great trochanter of the left femur. An incision was then made with a scalpel through the soft parts, commencing at the insertion of the ligamentum patellæ and carrying it downwards about six inches along the anterior aspect of the tibia, dividing the skin muscles and fascia until the periosteum was reached. These were carefully held apart by means of hooked retractors held in the hand of an assistant and the periosteum was then cut through, and very carefully elevated from the bone by means of a periosteal elevator. When the bone was brought into view, it was found to be a complete shell and quite hard. It resisted several attempts on the part of the operator to cut through it with a chisel. When finally broken off these sections of bone were found to be wholly devoid of nutrition. The entire diseased surface of the bone was then scraped away by means of a Volkmann's spoon, and the medullary cavity opened and washed out with warm sterilized water. The periosteum was then sutured separately throughout its entire extent by an independent set of sutures and the overlying tissues were brought together and closed with catgut sutures, an opening at the upper portion of the wound being left for the insertion of a drainage tube. The surface of the wound was then dusted with iodoform powder and the usual dressings applied over this.

The immediate results of the operation were of a most gratifying character. The patient had been obliged for over four years previously to resort to daily use of large hypodermic injections of morphine to secure relief from pain. Since the operation, however, this pain has disappeared altogether and for the first time in four years has she been able to enjoy her natural sleep at night without the use of narcotics of any description whatever. Her appetite has returned, her bodily strength has been improved, and the case promises to be entirely successful. The operator thinks that within two or three months at the furthest, sufficient bone regeneration will have taken place and consolidation along the line of the tibia have been secured to enable the patient sufficient support for the purpose of locomotion.

TREPHINING FOR EPILEPSY.

The second case I will show you is that of a young man, twenty-two years of age, with a family history as follows: He is the offspring of the marriage of an uncle and a niece, and enjoyed good health up to his fifteenth year when he developed an attack of typhoid fever of a rather mild character. Shortly after his recovery from this attack he was taken with epileptic seizures. At the beginning, these attacks came on at intervals of a month or two apart, but as he approached manhood, they became more frequent, so that lately be has been compelled to give up his work altogether and place himself under medical care. Various medicinal agents have been used towards overcoming this malady but without any meterial benefit whatever. Previous to his entrance to the Hospital he had on an average one convulsion a day, and, in connection with these seizures, he likewise suffered almost constantly from vertigo, headache, dimness of vision and melancholia. There was no history in his case of traumatism, except that at birth he was delivered by the forceps and at the temporo-parietal junction, immediately over the sagital suture on the left side, there was a well-marked depression of bone.

When the patient was referred to me by his physician, Dr. Randolph, of New Jersey,

he was anxious that I should promise an improvement in his condition, as a result of the operation, but this I declined to do. I, on the contrary, told him that an operation for trephining the skull was always a serious surgical undertaking, and one not devoid of danger to life, so that he must be prepared for any possible accident that might happen. I further told him that the operation might not result in any improvement in his condition. In spite of this plain statement of facts, the patient expressed himself to be desirous of placing himself under my care and taking his chances as to the consequences, inasmuch as he was unable to follow his usual occupation or do work of any kind on account of these convulsions.

I will proceed to trephine in this man's case with the use of an instrument of a narrow diameter and procced by slow stages until the cranial cavity is reached, when I shall enlarge the opening in the scull by means of a large Rougeur forceps and remove as much of the cranial plate as may be deemed advisable. With regard to the re-implantation of a disc of the fragments of the bone removed, that I shall not undertake to do this, for the simple reason that the operation is undertaken for the relief of pressure, not temporarily but permanently, and the replacement of bones in their former position would only leave things in very much the same condition as before the operation was performed. Furthermore, even though this course might be deemed advisable, it is almost invariably impracticable, for the simple reason that an osteoplastic operation of the scull in which bone is implanted, after being wholly detached, almost inevitably results in failure, the returned fragments exciting, either a local inflammation and ulceration, or if they take on adhesions, in the course of time undergo complete resorption and disappear.

If I shall find the bones of the skull in this instance diseased or extremely vascular, no matter how important the restoration of these fragments may be considered, yet the free oozing of blood through the divided surfaces of bone would interfere with the reunion of the fragments.

After the skull has been divided with the trephine, I shall take particular care after I reach the dura mater, and before the arachnoid and pia-mater are exposed, to employ no antiseptic on those delicate serous membranes, but to depend solely and exclusively on sterilized water at blood heat; because I have found out, that when antiseptics are applied on the denuded serous membranes of the brain, there is great danger of meningitis resulting, which in my observation, particularly in children, almost certainly results in a fatal issue, despite whatever precaution you may take to prevent its spread. Accordingly, I shall employ antiseptics only on the surface of the external wound.

The patient was then placed under ether and the scalp having been completely shaved, a large oval incision was made through the scalp, connective tissues, Galea-capitis, and the pericranium; the scalp, the muscle and the pericranium, being each, detached and reflected back from each other. On applying the trephine immediately over the seat of the depression, it was found that the bone had a hardness as great as that of ivory. After the bone was exposed, the diploe was reached, and the inner plate of the skull touched by the teeth of the trephine, the instrument was withdrawn, so that the disc of the outer plate of the skull might be removed before the trephine was carried nearer in the direction of the brain. When this disc of bone was raised, it was discovered that the trephine was on the bare dura mater; in other words, that there was no diploe: it had become completely absorbed and the bone thin and eburnated. The Rougeur was then taken in hand and the opening enlarged until it had a diameter of about two inches. The dura mater was next incised when the convolutions of the brain crowded up through the opening made in the osseous vault. The parts having been freely sterilized, the finger was introduced through the incision made in the dura mater between this membrane and the arachnoid, the brain substance gradually pressed back in different directions. No further depression was discovered, but there was considerable spouting of blood from one of the vessels between the convolution of the cerebrum which occasioned considerable trouble before it was finally controlled.

The parts having been freely irrigated with warm sterilized water, the dura mater was sutured with fine catgut, the pericranium replaced and sutured in the same material. The muscles and scalp were sewn consecutively with catgut sutures; and no drainage was employed, except a strand of catgut at either terminus of the incision. The surface of the incision was now freely irrigated with a bichloride solution of the strength of 1–5000 and the ordinary antiseptic dressings applied.

The patient recovered well from the ether but the following day he had a temperature of $100\frac{5}{10}°$ F., and a sensation of great heat and irritation in the scalp. He slept well,

however, and on the third day the dressings were changed, when it was found, as a result of the free use of the corrosive sublimate solution, his entire scalp was one mass of vesicles. It was clearly evident then, that if the bichloride solution would give rise to such an extensive dermatitis as this, on the hard and resisting scalp, that its action on the sensitive and delicate structure of the meninges might result disastrously to the patient. Vaseline was freely applied to the blistered scalp and soft, fluffy dressings as a covering over this.

The patient developed no seizure since the operation, save on the fifth day he had a slight twitching of the muscles of the face, but accompanied by no loss of consciousness, no vomiting, or no turgescence of the vessels of the face. His general condition has been very greatly improved, his sense of vertigo, headache and oppression in the employment of vision having wholly disappeared. The incision healed by primary union.

The remarks above given have been written three weeks after the operation was performed, and it is safe to infer that this case presented one of that favorable class wherein trephining may be considered as an operation that will lead to a permanent cure for epilepsy.

COMMUNICATIONS.

AN ESSAY ON THE HISTORY OF MEDICAL SCIENCE. [1]

BY W. H. WASHBURN. M. D.,

MILWAUKEE, WISS.

For the purpose of briefly reviewing the history of medical science, the residence of men upon the earth may be conveniently divided in four epochs. The first extending from an indefinite past to a time probably 3,000 years before our era, when medicine was practiced by Egyptian priests; the second from this time, say 3,000 B. C., to the appearance of the Greek physician, Hippocrates, born 460 B. C., the third from Hippocrates to Albrecht von Haller (1708–1777;) the fourth from Haller to the present time.

First.—During that long and remote period of time in which man, clothed in the raiment with which nature provided him, wandered alone on the face of the earth, not yet having acquired the faculty of articulate speech, he had no more knowledge of remedial agents or resources than is possessed by the grizzly bear.

Second.—But in obedience to the law of evolution, language developed; society became organized; the forces of nature were to a certain extent subdued to the uses of man, and wealth began to accumulate, so that all his time was not occupied in securing the absolute necessities of life; then there was leisure for meditation, speculation and investigation.

Civilization having first appeared in tropical or semi-tropical latitudes where the aspects of nature are comparatively speaking, terrible, the imaginative faculties of the mind were early brought into exercise. Events occurring suddenly without warning and without apparent cause, such as earthquakes, volcanic eruptions, inundations, epidemics of fatal disease, were attributed to the wrath of an outraged deity (and what a *horrible* insult to the intelligence of the 19th century, that it should be proclaimed from the pulpit of a Christian Church that the recent floods on the Atlantic coast were an expression of the wrath of God.) Disease thus being thought to be of supernatural origin, it followed naturally that the first remedy that suggested itself to the human mind was some sacrifice to appease the offended God; and if a sacrifice were to be offered, the individuals who would be expected to officiate with the greatest prospect of success would be the magi or priests, devoted to the service of the gods. It thus happened that the sacerdotal class very generally and over a wide extent of the earth's surface in both hemispheres, were the first to practice the healing art. Magic and incantation were the earliest means resorted to to effect a cure. When, however, in the course of time it was found by accident or experience that certain roots and herbs possessed remedial virtue, these were added to the armamentarium of the magician. Owing to the implicit confidence of the people in the efficacy of magic, these developed a very interesting combination of the practical and the magical in their methods. The *practical* recipe might contain any variety of roots and herbs applied in ointment or drunk in decoction, but *with* this the magical formula was also roquired to deal with the demon cause of the disease. The analogue of this practice can still be witnessed every day in the practical directions of the physician as to diet and regimen, while he gives a prescription to please the fancy of the patient, or in

[1] Read before the "Fortnightly Historical Club," Milwaukee.

other words incant, that is, enchant the demon cause of the disease.

As man first became civilized on the banks of the Nile, we naturally look there for the first evidences of the existence of a knowledge of medicine. We accordingly find that the traditions of the ancient civilizations, outside of Egypt, refer the origin of their acquaintance with medicine to that country. It is, however, supposed by some that progress was made in this science at an equally early date by the Assyrians and even by the Phœnicians.

There is in Berlin a papyrus of the 14th century B. C., being an essay on inflammation written in the ancient writing of Egypt. In the 11th century, B. C., there was in Egypt a college of physicians, and monumental writings confirm the fact referred to in Exodus that women practiced in certain departments of medicine there. The Egyptian Orus and Thoxeth have been regarded as the prototypes of the Greek Apollo and Hermes.

During the Egyptian bondage the Israelites acquired some knowledge of medicine; an evidence of such knowledge being afforded in the article by Moses in the diagnosis and treatment of leprosy. (Leviticus xiii, xiv.)

The Greeks derived their first knowledge of medicine from Egypt, and at the time of Homer they they had made some progres in that science. Ancient traditions say that the Centaur Chiron was the first Greek physician. His pupil, Æsculapius, about whose history there is much of uncertainty and mystery, became to the Greeks the God of Medicine. The sons of Æsculapius became physicians, and two of them, Machaon and Podalirius, were surgeons in the Greek army during the Trojan war. In the first battle on the banks of the Scamande, Menelaus received a severe wound. Machaon removed the "shaft" and

"Straight the broad belt with gay embroidery graced
He loosed; the corslet from his breast unbraced;
Then sucked the blood, and sovereign balm infused,
Which Chiron gave, and Æsculapius used."

Iliad iv. Line 248 *et. seq.*

In the third battle Machaon himself was so severely wounded as to render it necessary for him to be taken to the rear. Idomenens, in urging Nestor to convey "Great Machaon" with all speed to the ships is made to say:

"A wise physician, skilled our wounds to heal,
Is more than armies in the public weal."

Iliad xl. Lines 836 and 637.

It would, however, appear from the references to medicine scattered through the works of Homer that external medicine (surgery) was practiced almost to the exclusion of internal. Internal diseases were treated as in Egypt and Persia by incantation and magic. Among the Greek warriors in general, at the time of the siege of Troy, a knowledge of the treatment of wounds was widely diffused. An indication of this is furnished by an accident by Ulysses. While boar hunting the wild beast gored him in the knee, laying bare the bone. The wound was closed and successfully treated by his companions. Odyssey xlx. Line 500 *et. seq.*

The descendants of Æsculapius continuing the practice of medicine, gave rise to an order of priests devoted to the service of the god of medicine. They were called Æsclepialæ, Aristotle was of this order. Eighteenth in the line of descent from Æsculapius is Hippocrates.

Third epoch, Hippocrates to Haller.

The Greek mind was advancing and emancipating itself from a belief in sorcery and magic. Travelers were returning from journeys into Asia and Africa bringing with them foreign ideas.

Thales, the father of Greek philosophy, was of Phœnician descent, born in Miletus, Asia Minor, about 640 B. C. He resided for twenty-two years in Egypt, and while there imbibed philosophical ideas from the lower classes, which upon his return, he made the basis of Ionian philosophy. Following him came a great host of philosophers, and almost as numerous schools of philosophy. These philosophers were deductive reasoners, and their systems were based on that method. We understand by deduction reasoning from general truths to particular truths; from principles to facts; from the greater to the lesser; from the abstract to the concrete; the assumption of a general truth of principle and from that reasoning downward to particular facts or truths.

Hippocrates (460–350 B. C.) became a philosopher, turning his attention to medical science. It was inevitable that he should be powerfully influenced by the great speculative philosophers with whom he was contemporary. Antisthenes, Aristophanes, Democritus, Diogenes, Icocrates, Plato, Protagoras, Socrates, all of whom were deductive reasoners, and he hence proceeded in the same manner. By this method he sought to evolve from his own inner consciousness a knowledge of the nature of disease. It is unnecessary to enter at all fully into the speculations of Hippocrates, suffice it to say that to him is attributed the so-called

"Humoral Pathology," that is, that the essential seat of disease is in the fluids of the body. Disease, therefore, being an entity and seated in the blood, the practice of blood letting naturally followed, in the hope of thereby removing from the body the entity disease. He was a good observer and left voluminous works, many of which have been preserved to the present time. He recognized "the restorative power of nature."

The Greeks having entered enthusiastically into speculative philosophy and proceeding by deductive methods, there soon arose innumerable *schools* of philosophy; the various sects of the Ionian, Eleatic and Italian; the Cynic, Pythagorean, Epicurean, Sophistic, and this was inevitable from their methods of reasoning. Medical science likewise, having been founded on the philosophical speculations of Hyppocrates a deductive reasoner, necessarily presents a similar history down to our own century.

There were the Empirics neglecting anatomy and physiology and following only experience, without inquiring the *how* or the *why;* the Dogmatics claiming all authority for doctrine on theory; the Methodists who believed it unimportant to know the cause or nature of diseases, but only their common qualities, these being relaxation, contraction of minute passages, and a mixed state; the Eclectics who had no theory of their own, but tried to extract grains of truth from others; the Sceptics who were satisfied with asserting "That nothing could be known, nothing demonstrated."

Galen in the middle of the second century A. D. pursued the study of medicine in Alexandria, where he was a witness of and active participant in the controversies going on between the different sects in medicine, which were no less acrimonious than the conflicts between religious sects. He became the founder of a new sect or school based on the nature of medicines. He adopted the Hyppocratic ideas of the four elements earth, air, fire, water; the four humors blood, phlegma, bile and black bile; the four qualities dry, moist, hot, cold; applying the same qualities to drugs. He also endorsed the "Humoral Pathology." He exhibited wonderful ingenuity in explaining the numerous visible phenomena of disease, according to these principles. He was an industrious writer and an accurate observer of the symptoms of disease.

Celsus, although not the founder of any medical sect was the first Roman to make his influence felt in European medicine.

Until the fall of the Western Empire and the beginning of the Dark Ages, the Galenic school was dominant in Europe. During the Dark Ages what knowledge there was of medical science, together with nearly all scientific knowledge disappeared from Christendom; and was only saved from extinction by the Semitic Jews and Arabs.

While the Arabs occupied their own barren and dreary country they remained rude, barbarous, and ignorant, but Mahomet having arisen and established his religion among them, they embarked on a wonderful career of proselyting and conquest. They no sooner abandon the old scenes and subjected themselves to new environment, both as to scenery, people, soil and climate, whereby they were enabled to accumulate wealth, than they developed a capacity for civilization and intellectual advancement which will always excite wonder in the mind of the student of their history. Throughout the Moslem Empire great academies and universities sprung up.

At these institutions of learning medical science received its share of attention. The Arabs first raised pharmacy to the dignity of a science and produced the first pharmacopœia. They first applied chemistry to the practice of medicine. In surgery they made free and effective use of the knife and actual cautery. At this time, in Christian Europe, the sufferer from disease hastened to some Saint's shrine, expecting to be cured by miracle. Sancho, the Great, King of Castile, visited Cordova to receive treatment at the hands of Moorish physicians. Charlemagne employed for himself the services of the celebrated Jewish physician, Wintarius, and one at least of the Roman Popes employed a Jewish doctor. Ehazes, an Arab physician of Baghdad, 10th century, first described small pox and measles. Mesna, of Damascus, 11th century, produced the first work of any account on Materia Medica, a work which served in the time of James I, of England, as the basis of the first London Pharmacopœia, issued by the College of Physicians. The great names in Arabian medicine are Albucasis, Alkhendi, Axenzoar, Averrœs, Avicenna, Mesna, Ehazes, Serapin, besides a long list of lesser lights. For the amount of work done and the industry manifested by the Arabians, comparatively little actual advance was made in medical science, their chief merit being, that besides making important discoveries in pharmacy, Materia Medica, therapeutics and chemistry, they kept from oblivion what was already known.

In the 15th or 16th century, the chemical

school arose, of which Paracelsus was the most conspicuous representative. His name was Theophrast Bombast von Hohenheim, but regarding himself as a greater man than Celsus, he assumed the name Phillipus Aureolus Theophrastus Bombastus Paracelsus. The fundamental dogma of this school was that the human body contains within itself all the parts of visible nature "sun, moon, stars, and the poles of heaven" (whatever that may mean) and subject to the same chemical laws. Diseases were therefore to be treated by chemicals. Paracelsus believed that he could indefinitely prolong life by his mode of treatment, yet he himself died at the age of forty-eight years. He introduced into practice, antimony and calomel. His career produced but little effect upon medical science, and his followers degenerated into quacks and impositors.

Italy which was intellectually in advance of the rest of Europe early in the 16th century was no less so in medicine. Clinical lectures were first delivered in this century by DeMonte, at the Hospital of St. Francis, at Padua. Students of medicine from all parts of Europe flocked thither for instruction.

The 16th century having accomplished the reformation, probably the most momentous event in the history of mankind, and the human mind being in a measure released from the thralldom in which it had been held for a thousand years by religious intolerance and bigotry, rapid advances were made in all those things which go to make up civilization. Medical science participated in this movement.

The 17th century presents the names of Harvey, Bartholine, Hooke, Malpighi, Willis, all of whom made more or less important discoveries in anatomy and physiology. This was the century of Bacon and the Novum Organum, Des Cartes and the mechanical philosophy, von Helmont and his chemical explaination of morbid processess, Sylvius and Glisson, whose names have been given to certain anatomical structures.

Although Bacon in this century raised the inductive method to a working system, it did not produce any immediate result either upon philosophical speculation or medical science. The deductive methods of the preceding two thousand years had developed a corresponding characteristic in the mental processes of man, so that even men who appreciated the futility of the method, ably demonstrated it, nevertheless fell victims to hereditary tendencies, and the influences of environment. We see a notable instance of this in DeReed, one of the founders of the Scottish School of Philosophy. He ably demonstrated the weaknesses of the deductive method, announced his purpose to erect a system of philosophy by inductive methods, and then *deductively* laid the foundation of the "Common Sense School." The same thing is true of John Hunter, the great pathologist, who was never able wholly to emancipate himself from deductive methods.

The two principal schools of the 17th century were the Iatro-physical and the Iatro-chemical. Borelli, of Naples (1608-1679), who was the most celebrated exponent of the former, explained all the functions of the body on mechanical principles. The body was regarded as merely a system of tubes, and all the vital processes were explained by the principles of hydrostatics and hydraulics. This was a very popular and powerful school. Sylvius of Leyden (1614-1672), was the founder of the latter. The adherents of this school made extensive use of chemicals in the treatment of disease, and taught that every organ of the body had its own particular fermentation, and that abnormalities in the condition of these ferments is the cause of all disease. They denied the humoral pathology of Hippocrates.

The 18th century was one of great activity in medical science, as it was in every field of inquiry. But men not yet having abandoned the deductive methods of their predecessors, and laboring under the influence of that great obstacle to all advancement, exaggerated respect for the past and the great names of history, a great number of schools or systems had their origin in this century.

Bœrhaave (1668-1738), attempted to establish an electric school by selecting all things valuable from the writings of his predecessors.

Hoffman (1660-1742), attempted to reconcile the idealistic and materialistic schools of philosophy, and his medical theories from a part of his complete theory of the universe. According to him, health depends on a proper "tone," some diseases being produced by excess of tone or "spasm" and others by lack of tone or "atony."

Stahl (1660-1734) opposed the materialistic school of philosophy, carrying his views into medical speculation. The theory of Stahl "Animism" attributes to the soul the ordinary functions of animal life in man. The symptoms presented in sickness

were simply the efforts of the soul to rid itself of disease.

John Brown (1735-88), of Scotland, founded what was known as the Brunonian School, based on the principle "excitability." He taught that some external or internal excitant gives rise to all the vital phenomena, that diseases are all either sthenic, that is, dependent on too great excitability or asthenic, dependent on deficient excitability. This system did not exercise much influence outside of Scotland.

John Hunter (1728-93), the great Scotch patholigist promulgated the theory that diseases are seated in the solids of the body rather than in the fluids. This theory exerted a very salutary influence over the then prevalent practice of indiscriminate blood letting.

The last system builder whose name deserves mention is Hahneman, whose speculations have given rise to the Homeopathic School. This system requires a fuller notice than the others because it is the only *school* of medicine which even in name has survived the inductive methods of the 19th century.

Hahneman (1755-1843) in medicine, like Reed in philosophy, fully recognized the untrustworthiness of the prevalent deductive methods, and vigorously opposed them, but, like Reed, in attempting to improve upon medical science as it then existed, he built up another by the identical methods he had been engaged in opposing.

His system is based on the law of therapeutics known as "Similia similibus curantur," that is, in order to cure a disease a medicine must be administered which, if given to a person in health, would produce symptoms similar to those manifested by the disease. This theory was not, however, original with Hahneman, for Hippocrates speculated upon it, and still later, Paracelus entertained it, laying it down more specifically and almost in the very words afterwards used by him.

This was not, however, all of homœopathy. According to it the "vital process is neither mechanical, nor chemical, nor stoechiometric, nor electro-galvanic, but is a higher power which avails itself of these subordinate principles in the performance of its functions." And this being so it was theorized that drugs which act upon the vital processes do so by virtue of "some occult self-existing force"; the causes of disease were impalpable, immaterial and spiritual, and to be removed by drugs possessing "some occult *self*-existing force." Disease was in fact simply the "totality of the symptoms" and was a "spiritual dynamic derangement of our spiritual vital principle." From these speculations arose Hahnemann's doctrine of the dynamization or potentization of drugs by dilution. He carried this principle so far as to teach that when a drug was carried to a *high* dilution, olfaction was all that was necessary to produce its effect, and that if, in making the 30th attenuation of *drosera*, the mixture was shaken twenty times instead of ten, a dose of it might prove fatal to a child. He taught that seven-eighths of all chronic internal diseases were caused by *psora* or the itch driven in; that investigations in pathology were useless as "nothing can be known of disease with certainty except its perceptible phenomena," that is its symptoms; he denied the power of nature to heal, attributing to drugs alone the power to *cure* disease. "That state of the organism which we call disease cannot be converted into health but by the aid of another affection of the organism excited by means of medicines." It is almost needless to say that the disciples of Hahnemann have for a long time abandoned his theories with respect to the nature of disease, potentization of drugs by dilution, and psora or the itch. And moreover a very large proportion of them while they believe there is such *a* law as that of "similia" do not claim that it is *the* law. Homœopathy, therefore, being a deductive and theoretical *system* has never been able to produce one single great discovery in any branch of medical science, either preventative or curative, or in any of the collateral sciences, or one of sufficient importance to attract the attention of mankind, as to be recorded on the pages of medical history.

This brings us to the fourth epoch—Haller to the present time.

The dawn of a better day was about to break upon medical science. Inductive methods after a slow and painful struggle were forcing themselves more and more upon the attention of investigators in every department of science. The inductive method is the direct reverse of the deductive; it is reasoning from facts to principles; from the lesser to the greater; from particulars to generals; from the concrete to the abstract; the observation of a vast number of facts and the carrying on of multifarious experiments then, is the distinctive feature of the inductive method, and generalizations are only reached after the most exhaustive and elaborate experimentation and study. By this method nearly, if not quite, all the great discoveries in science have been made.

Albrecht von Haller (1708–1777) was born in the city of Bern, Switzerland, and became a professor in the medical department of the University of Göttingen. He saw the hopelessness of arriving at scientific truth by the current methods and casting theory entirely aside, expressed the opinion that the only way to develop *rational* medicine is by studying anatomy, physiology, pathology and the physiological effects of remedial agents; that for good diagnosis we need pathology, and for pathology, physiology is indispensable.

Rational medicine then began when Haller recognized the fact that "the laws of nature are not things which we can evolve by any speculative method. On the contrary we have to discover them in the facts; we have to test them by repeated observation and experiment. In proportion only as they hold good under constantly increasing change of conditions, in a constantly increasing nnmber of cases, and in the greater delicacy in the means of observation does our confidence in their trustworthiness rise."

Since the time of Haller the advancement of medical science has gone on with ever accelerating speed, so that the medicine of yesterday is not the medicine of to-day, and to-morrow that of to-day will represent the historic and dead past. Haller was professor of anatomy, botany, and the practice of medicine and surgery in the University of Göttingen. To-day a first-rate medical school requires from eight to fifteen professors to teach the same subjects. This is simply given as an illustration of the growth of these sciences during the past hundred years.

To merely mention the positive advances made by medical science in this fourth period would be a weary task, and would be tedious and uninteresting to the general reader, but I cannot close without adverting to certain men and certain discoveries which may almost be said to mark epochs in medical practice and thought.

Marie Francois Xavier Bichat (1771–1802) opened a new era in medicine by directing the attention of investigators to the study of *tissues* of the body. He only lived thirty-one years, but his indefatigable energy, profundity of knowledge and reach of thought, justly entitled him to the epithet of "father of general anatomy," His great work on "General Anatomy" appeared in 1801, one year before his death, and is now, of course, ancient literature, but the impulse it gave to the study of elementary *tissues* of the body has given rise to the present science of histology, that is, the minute anatomy of tissues. From this has been developed the science of pathological or morbid anatomy. Bichat by his plan of studying the tissues hoped to arrive at some knowledge of the causes and nature of life itself. In this grand object he of course failed, but his name will be handed down to posterity not only as one who made important additions to an old science but laid the foundation of a new one.

The discovery by Jenner of vaccination need only be mentioned,

Marshall Hall (1790–1857) discovered the reflex function of the spinal cord and the excito-motor system of nerves, made public in 1832 and 1837. Magendie and Bell about 1825 discovered the existence in nerve trunks of separate fibers for motion and sensation, thus rendering it possible to diagnosticate diseases of the spinal cord, and laying the foundation for the present science of neurology. These discoveries deserve to rank with that of the circulation.

Lænnec (1782--1826) studied the sounds produced in the chest in the act of breathing, both in health and disease, also the sounds produced by the heart's action. He made minute and voluminous notes of what he heard, supplementing these observations by a very large number of post-mortem examinations. By these studies he was able to identify the sounds heard over the thoracic walls with the pathological condition found after death.

These studies, with that of those who have been his followers in this field of investigation, have raised physical diagnosis by means of percussion and auscullation to a science. Prior to this time endocarditis had no place in the classification of diseases and pericarditis was only guessed at, while valvular diseases of the heart were only located after death, on the autopsy table.

The labors of Richard Bright culminated when in 1827 he published a rather modest essay entitled "A Report of Medical Cases." This essay elucidated the pathology of those affections of the kidneys now known as Bright's Disease.

The publication by Beaumont in 1833 of his studies on digestion by means of experiments and observations on the historical Alexis St. Martin threw a flood of light on the physiology of this procees. It was thus learned that digestion is not completed in the stomach; that the active agent in stomach digestion is an acid liquid secreted by the walls of the stomach, and that this secretion is not a constant one, but is only poured out under the stimulus of food.

Schönlein, in 1839, discovered that the contagious disease of the scalp known as "favus" is caused by a microscopic parasite, to which the name of "Achorion Schönleinii" has been given. This discovery proved to be the starting-point in wonderful developments in our knowledge of parasitic diseases.

The discovery of Anæsthesia need only be mentioned; also the recent discovery of the local anæsthetic properties of cocaine which are of great service in minor surgical operations.

In Materia Medica and Therapeutics the work of discovery has gone on so rapidly that we now have a long line of valuable remedies which were entirely unknown a few years ago.

The discovery by Koch within the past twenty years that the essential cause of tuberculosis is a bacillus, has led to a great activity in microscopic studies of contagious diseases, and there are now strong indications that many of them will be proven to be due to the presence of microscopic germs. This discovery may be said to be the starting point of Medical Bacteriology.

The discovery that a microbe, the "Streptococcus Pyogenes Albus" is the essential factor in pus formation and that certain substances in solution destroy them, led in the hands of Sir Joseph Lister to "Antiseptic Surgery" which has prolonged thousands of lives during the few years it has been practiced. It has rendered otherwise grave operations comparatively safe, and has opened the wide field of abdominal surgery.

Lastly, I will speak of Louis (1787-1872), not last however, because least. On the contrary, I believe his labors and that of his co-laborers have done more to advance the efficiency of medical practice than labor in any other one direction in medical science. His opportunities for studying disease in the hospitals of Paris were immense, and he made the best possible use of them. He here studied the natural history of disease entirely uninfluenced by medicines. He spent many years in this work, keeping the most minute notes of thousands of cases. The result of these observations, was the discovery that certain diseases are, to use a term first applied by Dr. Jacob Bigelow, of Boston, self-limited, notably typhoid fever and pneumonia; that many of them tend intrinsically to recovery; and moreover that certain events in the course of disease, for example, hemorrhage from the lungs in the early stages of tuberculosis, are conductive to recovery. These discoveries have had a wonderful influence over the practical part of medicine, rendering the physician less vigorous in "combating" the *disease*, and more solicitous to maintain the vital forces of the patient until the disease has had time to run its course.

But there are still 17th century ideas remaining in the world and they die a prolonged and hard death. Thus, so firmly fixed in the *popular* mind is the notion of the physician's *antagonism* to the supposed *entity disease*, that the term "Allopath" is not regarded as misapplied, inaccurate, and a libel on a great body of scientific workers, even by those who known full well the derivation and signification of the word.

The rational physician then of to-day denies that disease is an entity in the body to be driven out like a wolf from a sheep fold; denies that it is impalpable, immaterial and spiritual and only to be *cured* by medicine; but affirms that it is a "perversion of the material structure of the body or some of its parts." He believes in the "Vis Medicatrix Naturæ," the power of nature to heal; he in fact knows that it *alone* effects a *cure* and that he is simply the "gentlemanly hod-carrier" of nature, supplying it may be materials with which she can work on removing obstructions from her way.

THE TREATMENT OF ACUTE DYSENTERY.

BY ROBERT C. KENNER, A. M., M. D.,
LOUISVILLE, KY.

There is possibly no disease which will more greatly tax our resources, and which will require more skill and patience in its management than acute dysentery.

[1]Read before the Kentucky State Medical Society, May 28th, 1891.

The room which the patient occupies should be light and comfortable. While it should be properly ventilated, care should be exerted to prevent our patient from becoming chilled at any time. The bed covering should be adequate to prevent any draught of air from producing this effect. The patient should be directed to keep his bed. Any movement on his part will tend to increase the number of actions from the bowels, and at the same time make demand on his strength, and, in cases where there is much debility, of course, make possible a failure of the heart. Let us divide the cases of acute dysentery into two classes:

First—The Ephemeral: This embraces a class of cases all practitioners meet; it is the mildest form of catarrhal dysentery, and commonly lasts no longer than twenty-four hours to four days, even when no treatment whatever is employed. These cases are attended with slight inflammation, and are, in every way, ephemeral. It the *second* class I shall include those cases which persist, after four days, with increasing severity, or those which, from the beginning, show themselves essentially severer than the first-named variety from their incipiency, and which are denominated catarrhal and diphtheritic generally by the anthorities. Between these types, however, there is only a difference of degree of intensity of the disease, and this division of the subject into two categories has only for its object the convenience it affords in the discussion of the treatment. In the treatment of the first-named variety, rest is the essential curative factor. But this may be increased by producing its conditions. To insure perfect rest it is best to administer sulphate-magnesia and sulphate of morphine. We in this way remove all irritating matter from the bowel, and the opium brings about the desire to sleep. These supply the demands in those cases perfectly, and it is rare for another dysentric action to appear after the sulphate magnesia has acted. The *second* class of cases, however, yield not so kindly, and for its relief, the methods of treatment and various drugs used are very numerous. It shall be my aim in this paper to give consideration of only those which have been attended by results that would command respect or which have been advocated by gentlemen whose prominence and reputation as investigators in medicine inspire our confidence. A treatment which numbers among its advocates Bartholow and several good observers is one which advocates the administration, as a leading remedy, of the sulphite of magnesia. This remedy alone is one which, in my hands, has not proven satisfactory, but I depend on it rendering me assistance in connection with other remedies. A careful trial of the drng will not, I think, demonstrate its value at all as a curative remedy. It has failed to lessen the duration, in my cases, to the extent which I accomplished with other remedies. I am inclined to believe that the treatment by saline cathartics alone owe their place in medical literature to an illogical understanding of cures that appear to be accomplished by them.

First, there will be, in all epidemics of dysentery, cases belonging to the first-named class, and others not quite so mild which recover in a few days. These are, illogically, put down as cures brought about by sulphate magnesia, while all experienced physicians know that many cases would have recovered without any treatment. Again, the treatment by salines has gained strength by a comparison of statistics of cases treated by it with those treated by methods formerly in vogue. These statistics embrace those treated by mercury, blood-letting, etc., and are not of a character with which to compare any modern treatment. My own experience has been against the treatment, yet I find the sulphate magnesia a valuable adjuvant in the treatment of this affection. It evacuates the bowels well, and exerts a mild refrigerant influence. In the year 1859, Mr. E. Scott Docker, an English army surgeon stationed on the island of Mauritius, used ipecac in fifty cases, losing but one patient out of that number. To him belongs the credit of again bringing to the consideration of the medical profession a drug which for a long time had been buried in oblivion. This remedy had been introduced by Piso, who had seen the brilliant results which had been attained in the treatment of this disease by the natives of Brazil. It was used as a secret remedy for a long time, with much success, in France. Owing to a quarrel over the profits from its sale, the secret was made public. For a time the demand was very great. But it came, after a time, to be regarded as less valuable than was at first thought, and it soon fell into disuse. I have always thought the abandonment of this agent was due to its indiscriminate use, and to its application in cases of diarrhœa due to many causes. I believe it is not exaggeration to say that since the introduction of ipecac by Docker, thirty years ago, it has been the treatment most relied on by the greatest number of practitioners, and has obtained the greatest meed of praise at their

hands. In regard to its action, allow me to quote from Begbie: "The therapeutic action of the remedy has been variously ascribed to its nauseant, its diaphoretic, and its laxative or purgative effects." The latter was the view entertained by that distinguished writer, Sir John Pringle. Dr. Maclean thus expresses himself in regard to it: "It is probable ipecacuanha owes much of its usefulness in this disease to its action as an evacuant. It is also a blood depurant of an effective kind. It appears to increase the secretion of the whole alimentary canal, as well as the liver and pancreas; under its use tormina and tenesmus disappear, and feculent evacuations are more quickly restored than by any known remedy." Ewart and other great observers regard it as without a doubt, the most valuable remedy at our disposal. Shoemaker mentions that this drug has been used with the most striking results in the treatment of dysentery.

I have found, from my conversations with medical men, that they, to a large extent, fear the emetic qualities of this drug to such a degree that they hesitate to use it. This fear is ungrounded. It does not produce emesis at all in a large percentage of cases if the proper precautions are observed. But if it should produce emesis, this should not deter us from the use of so great a remedy. Emesis does not continue long, even when it occurs. It does not, except when there is great exhaustion, carry with it the slightest danger to life. But on the other hand, the production of emesis has been recommended as a curative agent by able observers like Pringle, before the ipecac treatment had any following in this country or England. Relative to its mode of administration, allow me to quote somewhat at length from Maclean. He says: "The patient should be at once ordered to bed, and as quickly as possible brought under the influence of ipecacuanha in large doses. Some insist on the propriety of first giving a full dose of Battley's sedative, tinct. opii, or a few drops of chloroform, with the intention of making the stomach tolerant of the remedy, and restraining nausea and vomiting. I believe that the sedative in some cases is useful, and acts in the manner just described. On the other hand, I have often seen ipecacuanha do its work well, and with little disturbance of the stomach, without opium. Should it be determined to premise opium, thirty drops of the tincture, and a half hour after followed by from twenty-five to thirty grains of ipecacuanha, which should be given in as small a quantity of fluid as possible; a little syrup of orange-peel covers the taste as well as anything else. As already advised, the patient should be kept perfectly still, and abstain from fluid for at least three hours. If thirsty, he may suck a little ice, or a teaspoonful of cold water at a time may be allowed. It is seldom that, under this management, nausea is excessive, and vomiting is rarely troublesome, seldom setting in for at least two hours after the medicine has been taken. The abdomen should be covered with a large sinapism, or a sheet of spongio-piline sprinkled with a little turpentine, after being wrung out of hot water. In from eight to ten hours, according to the urgency of the symptoms and the effect produced by the first dose, *ipecacuanha*, in a reduced dose, should be repeated, with the same precaution as before."

In my own practice the use of ipecac is, however, somewhat differently combined, though in the main I have followed the method just quoted from Maclean. It is my custom to give an hypodermic injection of from one-fourth to one-half grain of sulphate of morphine. I have also a piece of thapsia plaster applied over the epigastrium. My results with the ipecac treatment have been all that could be desired, and I have found that in ninety per cent of the cases treated with it as the principal agent, it brought about a cessation of the disease quicker, by from five to fifteen days, than other methods. The length of time which was consumed in bringing about the results will be considered later on.

It is my practice to give salol, in doses of five grains, every three hours, after six hours from the initial dose of ipecac. This has, I feel assured, rendered me substantial assistance in that it exerted an antiseptic action on the alimentary canal, relieved the gaseous distension and colic, which are often so annoying as to cause the patient the greatest discomfort and pain. Salol has, itself, some reputation as a remedy in dysentery. I am not prepared to speak of its powers when used alone, but I am sure when given along with ipecac its virtues will display themselves to the satisfaction of any candid observer.

It is important to say that I premise the treatment of all cases of acute dysentery to which I am called by a dose of sulphmag, and six hours thereafter, when there has been a thorough feculent evacuation, I administer the ipecac in the manner already outlined. Throughout these cases it

was necessary in many instances to employ as adjuvants many other agents, which will be considered under seperate heads.

The treatment by opium has the endorsement of Sydenham and others down to Prof. Flint, and several other able physicians have given it the most sweeping praise. It is usual for those who use it as the leading remedy to first clean out the bowels with castor-oil, or another laxative, and then give opium at such intervals as will secure quiet.

In regard to the use of opium in dysentery, Heubner says: "Especially is it impossible with opium or morphine to keep the bowels at rest all the time. The colic and tenesmus are, indeed, moderated for awhile, but they return after a time, even in spite of larger doses, and are then more violent than before. Besides this the state of stupefaction and heat into which the patient is brought by the use of opium is decidedly unfavorable in dysentery. I would, therefore, in common with the majority of writers of this century and the preceding one, not give my approval of the methodical use of opium in dysentery, and would only use this drug temporarily, and as a palliative remedy.

My experience bears out the correctness of these words of Heubner, and it is only when their is great pain, or persistent nausea, or, as has before been stated, we desire to prevent nausea, or sleeplessness, which no other drug can supply, that I administer opium. The reasons given by Heubner must be regarded as a valid and unanswerable argument in favor of the surrender of opium as a curative remedy of dysentery. At the same time its place could not be supplied well, and it will afford us assistance which we will not find easily in other palliative agents. The treatment by rectal injections of a solution of nit. of silver, or alum, or other astringents, is a practice which has had a following from the time of O'Beirne, in 1834, down, who have claimed results which were the most brilliant imaginable. Recently Prof. Whittaker has advocated this treatment, many able observers have given testimony as to the benefit derived from the treatment of dysentery in this way. I have not found it a treatment upon which I could place reliance, and have several times regretted having resorted to it. Just now there is not any generally agreed method of using these enemas. In children they are difficult of application, and several times I have found them very painful. It is possible at some future day the limitations of this treatment of dysentery may be outlined, and then it may be found that a certain class of cases will yield to them which before were intractable. Heubner, on this point, very justly says: "We must not expect too much from astringent enemas, for in the majority of severe cases much too small a surface is reached. In the dysenteries of 1870 I used the much-renowned nitrate of silver enemas almost without any evident good results; on the contrary, the pain was increased."

The treatment of blood-letting, or mercurials, have not at this time sufficient following to warrant a consideration here. Their place is only an historical one. The use of tannic acid, sulph. of copper, nit. silver, catechu, sub. nit. of bismuth and a long list of astringent medicines have been lauded by different writers at different times, but no one of these can be said to possess the power of abridging the duration of the disease. Yet when the disease is subacute, or when there seems to be a want of tone of the alimentary canal, these agents occasionally do good. The nitrate of silver sometimes is excellent in this demand. So will arsenite of copper, under circumstances like the one spoken of, yield us the happiest results. Recently the arsenite of copper has been lauded as a remedy of surpassing value, but in a limited experience with it I have not found it all that could be desired.

The question of diet is one of the greatest importance. Nearly all practitioners have seen the balance of life tip to the wrong side from improper indulgence in food. The diet should be fluid as nutritious as possible. Milk, fresh, and when necessary peptonized, is an important article. This should be given at frequent intervals throughout the disease. I most generally give some eligible preparation of pepsin immediately after taking the milk. This assists the weakened digestive forces, and prevents in that way the formation of milk curds, which would be as injurious to the diseased surface of the gut as the passing of feces. I alternate the milk with liquid beef peptonoids, and find the result to be good. The diet must be watched with considerable care until the convalescence has progressed unto a very considerable extent. Some authorities recommend allowing patients to eat ripe fruits when convalescence has set in fairly. This I have tried in ten cases, with the result of relapses in all of them. I was unable to attribute it to any other cause, and must, therefore,

charge it to the fruit. Since this unpleasant experience I have not allowed my patients to eat fruits—at least early in the convalescence. In fact, I charge them to make this one of the last articles to return to.

The question of the use of stimulants is one of the greatest importance in its bearings on the treatment of this disease. When the nature of dysentery is borne in mind, that it is an exhausting disease—one which soon brings stout people to be lean and strong ones weak—and in those who are delicate there is constant over exertion put on the heart—I think it will not be questioned that the proper administration of stimulants is a most proper and necessary course of action. In those who are strong it will not be necessary to give stimulants so often—every two or three hours, or oftener, if the patient is required to get up often. In delicate persons, brandy or some other stimulant should be given every hour or oftener, and in such quantities as will keep the volume of the pulse good. This will require an amount which the study of the parsicular case only reveals. Brandy, or milk-punch, or egg-nog, will be about our best remedy.

Another important consideration is fever. When the temperature does not attain a higher range than 103° F., it may correctly be regarded as a conservative process, and does not call for special medication. When there is a fever which we think is due to malaria, then it is our duty to prescribe quinine, but not without there is evidence of this fact. There are cases in which the fever will mount to 105° or 106°, and in those cases it is to be determined what measures shall be directed to the fever. I believe that if the fever is malarial nothing but quinine should be given; and, due to other causes, our reliance in reducing it should be put upon sponging the body with tepid water; and we should not fly to antipyretics until the last resort. These agents depress the heart, and make no substantial change for the better in the weak; yet it is occasionally right to resort to them, but it should not be done unless the fever attains a dangerous height.

There is probably no more distressing feature in this disease than tenesmus. For its relief several remedies have been offered, but none are all that we could desire. The application of bladders of cold water to the anus has been, in my hands, one of the best remedies. I employ occasionally leeches to the margin of anus, but find them no more beneficial than the cold bladders, and their application is often disagreeable to the patient. Carbolized vaseline smeared in and around the anus will afford a measure of relief and is worthy of trial. Prof. Loomis and several authors like warm applications to the abdomen. I have found poultices and all manner of applications which are laid upon the abdomen useless and awkward. They have to be removed when the patient arises, and are constantly falling off. This leaves the abdomen more exposed than if nothing was applied. I use in many cases turpentine liniment applied over the abdominal surface. This is especially valuable in cases where there is much gaseous distension of the bowels.

In conclusion, allow me to return to the ipecac treatment and say that out of sixty cases treated by this method ninety per cent. recovered in an average of twelve days. The remaining ten per cent. continued and became chronic or went beyond this time considerably. The test of the value of a given treatment is its ability to lessen the duration of the disease. In Flint's cases under the opium treatment the duration was from four to twenty-one days. This, of course, comprised cases of the ephemeral type. Heubner's cases are put down as light cases, eight to thirteen days; diptheritic, three to four weeks. When these facts are brought to mind it would seem that ipecac treatment is above all other methods at our disposal.

TUBERCULOSIS.[1]

BY R. W. STEWART, M. D.,
PITTSBURGH.

Tuberculosis may be truly said to be the pest of humanity. Few diseases are so insidious in their onset, and none so disastrous in their results. One-seventh of the human race is destroyed by it.

What tuberculosis is, the lesions it produces and the best means with which to combat it, will be my object to describe in this brief paper. Nine years ago Robert Koch proclaimed to the scientific world and conclusively proved, that tuberculosis was the result of the growth in the tissues of a micro-organism called the bacillus of tubercle. So conclusive has become the proof of Koch's assertions, so thoroughly has all opposition been swept away, that it would be reprehensible on my part to needlessly occupy your time with a history of the discovery of the bacillus of tubercle, and the steady ad-

[1]Read before the Allegheny County Medical Society, May 19, 1891.

vancement of the views originally promulgated by Koch until all opposition was silenced and antagonism turned to enthusiastic support.

The manner in which the tubercle bacilli gain entrance to the system are various, the respiratory and alimentary tracts being the most common seats of entrance, but there is abundant testimony to prove that abrasions in the skin may afford a vulnerable point for the entrance of the bacilli as is demonstrated in the production of lupus.

The bacilli may remain localized at the seat of entrance, or circulating in the blood current may fail to find a suitable location for their growth, and be ultimately destroyed or removed with the excretions. A less favorable termination, however, frequently takes place. The bacilli may find a nidus where the conditions are favorable for their growth in almost any of the tissues, but most frequently in the lungs, where they produce the disease called consumption; in the lymphatic glands, where they produce the disease called scrofula, a term now rendered obsolete; in the skin, where it produces lupus; in the bones, where they are said to produce twenty-five per cent. of all chronic inflammatory diseases. The joint structures, the tendons and tendon sheaths, the peritoneum and the brain are frequently affected. In fact, but few of the tissues are exempt from their inroads.

In acute miliary tuberculosis almost all the organs of the body become simultaneously affected. This seldom or never occurs from a primary infection, but nearly always from the absorption of some caseous material from some pre-existing tubercular focus, by which a quantity of the bacilli or their spores are liberated in the blood and attack the tissues, whose vitality is already impaired, and hence rendered less resisting by the presence of a pre-existing disease. So varied are the manifestations and treatment of tuberculosis, according to the tissues affected, that it would be impossible in a paper of this character to do the subject justice. I have therefore chosen to confine my remarks as closely as possible to the condition known as pulmonary tuberculosis, because it is the one with which as a body, we are most familiar and will, I hope, elicit a very free discussion. I will take it for granted that you are familiar with the histology and pathology of tubercle, subjects too well known to permit of discussion, and will pass at once to the consideration of the predisposing causes, the symptoms and treatment of pulmonary tuberculosis.

Prominent among the predisposing causes must be placed the hereditary tendency to the disease. It is not to be understood that the disease itself is inherited, but that the patient inherits from the parent, pulmonary tissue which has insufficient resisting power to repel the invasion of the bacilli. It may be well to remember that in a disease so prevalent as the one under consideration that the atmosphere under favorable conditions, is frequently contaminated with the tubercle bacilli or their spores, chiefly as the result of the drying of tubercular sputa, and it must happen that every individual, or at least those living in communities where tuberculosis exists, is frequently exposed to the contagium of the disease. If we also bear in remembrance that there is a standing declaration of war to the death between the bacilli and the tissues, and that in the conflict the weakest must succumb, we will readily realize why a parent with diseased lungs may bequeath to his posterity a legacy of tuberculosis. Another potent cause of pulmonary tuberculosis is prolonged contact with the contagium of the disease, as may be witnessed where the husband whose wife is tubercular contracts the disease, or *vice versa;* or in the melancholy but numerous instances where a member of a family without a tubercular ancestry contracts the disease, and the remaining members who have been in intimate contact with the patient are subsequently attacked.

Any condition or disease which lowers a patient's vitality is a predisposing cause of pulmonary tuberculosis, and it is the more powerful if the condition directly affects the respiratory apparatus. Among such may be mentioned imperfect development if the chest, occupations which hinder free and full respiratory movements, bronchitis, pleuritis and pneumonitis, the latter especially if the inflammatory exudate is slow in undergoing resolution.

It is unnecessary to pursue this part of the subject further, and I will only emphasize what my remarks must have indicated, that tuberculosis is a contagious disease, but in order that the contagium may thrive there must be conditions in the soil on which it is planted that are favorable to its growth.

When pulmonary tuberculosis has reached an advanced stage its manifestations are so plain, that he who runs may read; there is something so characteristic in the combination of symptoms that go to form the make-up of such a case, that a diagnosis is already made before the patient has been examined. The emaciated figure, the stooped

shoulders, the sunken chest, the rapid breathing, the hacking cough and the clubbed fingers, are so unmistakable and so familiar that even the laity are seldom in error in their conclusions. But of such cases I have little to say; they have probably passed the point where we can aid them; their fate is already sealed, and the utmost we can do is to ward off a little longer the impending doom, and ease the rugged pathway along which the victims of this cruel and relentless disease must tread until death, less merciless, stills the hacking cough and in eternal sleep throws the mantle of oblivion over the scene.

Of much greater importance to us and to the patient is the diagnosis of the disease in the early stages, important because the earlier the disease is recognized the easier is it to be contended with, and the more beneficent are our therapeutics.

Of such importance do I consider the early diagnosis of phthisis that I feel constrained, in order to emphasize its importance, to digress from the subject, and speak a few words on the curability of phthisis. Consumption is usually regarded, by the laity, as invariably a fatal disease, and I fancy, also, by some of our professional brethren, especially that class not yet extinct, who have a contemptuous disregard for physical diagnosis and microscopical achievements. And they have good reasons for such judgments, since the disease is seldom recognized by them until it has reached a stage where its progress cannot be retarded, nor a fatal termination averted. That consumption is necessarily a fatal disease is a false and grievous conception, and the sooner it is totally eradicated the better will it be for the profession and humanity.

Consumption is often cured when in the incipient stage. This fact was early impressed on me by numerous illustrations which I witnessed a few years ago among the river men while under treatment in the marine wards of Mercy Hospital. These men are notoriously careless of their physical welfare, and their occupations are of such a nature that pulmonary complaints are rife among them. At the time I referred to I was anxious to familiarize myself with the early symptoms of phthisis, and made the routine habit of examining every marine's lungs, regardless of the disease for which he was admitted. I was astonished at the number of cases of incipient phthisis that were discovered, often among those who did not complain of any pulmonary trouble, or, at the most, of a slight cough. It was even more astonishing to witness the frequency with which the physical signs of incipient phthisis would disappear under improved hygienic conditions and appropriate treatment. It is only fair to add that in these cases the diagnosis was based on the physical signs, as a microscopical examination of the sputa was not made. Since that time I have witnessed a number of similar cases, although such a happy termination does not always take place.

I do not put before you my own limited experience as conclusive proof, but will bring forward the cold facts as gleaned from a source into which mistakes in diagnosis and results are not liable to creep, namely: *post-mortem* examinations. The following is quoted from John Hughes Bennett's article on phthisis, in Reynold's System of Medicine (Vol. II., page 130): "The careful *post-mortem* examinations now made with such regularity in our large hospitals have demonstrated the frequent occurrence of old condensations, cicatrices, and calcareous concretions at the apices of the lungs in persons of advanced aged who have died of other diseases. In 1845 I pointed out that in the Royal Infirmary of Edinburgh they occurred in the proportion of from one-fourth to one-third of all the individuals who died after the age of forty. Roger and Boudet had previously shown that at the Salpetriere and Bicetre Hospitals in Paris, among individuals above the age of seventy, they occurred in one-half and in four-fifths of the cases respectively. There can be no doubt that these cicatrices and concretions indicate the healing and drying up of cavities and softened tubercular matter at some previous period in the life of the individual, and the consequent spontaneous cure of the disease in a considerable number of persons."

I return to the diagnosis of phthisis in its incipient stage, the importance of which I endeavored to impress upon you by pointing out that in this stage the disease, under proper hygienic and therapeutic treatment, was frequently curable.

Phthisis, in its incipient stage, is usually a very insidious disease. There is no line of demarcation to distinguish when health ended and disease began. Perhaps the very first indication is a condition of malaise—an indefinable feeling of not being well, without any concomitant symptoms to indicate pulmonary mischief. Often there is tenderness over one or both the apices of the lungs, or fleeting pains may attract the patient's attention to this region. A slight cough, associated with but little expectoration, is a

usual concomitant, although the cough may be severe and the expectoration profuse where a bronchitis has been an accompaniment or predisposing factor in the causation of the tuberculosis.

Another symptom of considerable significance is a slight elevation of temperature, which may not be over half a degree. If the temperature should be elevated on several successive examinations, and if there is no obvious cause for it, the presence of tuberculosis should be strongly suspected, and a careful examination of the lungs should be made. As regards the method of examining the lungs a few words may be said. The patient should be stripped, only the slightest covering to the chest, such as light under-clothing, is admissable. This rule should be rigorously observed, regardless of whether the patient be male or female, child or adult. If the patient, through false ideas of modesty, should object, it is the physician's duty to refuse to stake his reputation on a hazardous guess as to the condition of a patient's lungs, whose sounds are muffled from his ear by the interposition of a pair of corsets, and the various other paraphernalia which deck the female form.

The physician, who, under such circumtances, ventures to give an opinion as to the presence or absence of incipient phthisis, must either be gifted with an abnormal acuteness in hearing and discrimination in eliminating the extraneous sounds produced by the respiratory movements on the wearing apparel, or, what is more likely, he has a firm conviction that if he did hear the pulmonary sounds he would be unable to tell what they meant, and very considerately draws the line on his imposition at the point which necessitates the removal of the patient's garments.

To my mind the most characteristic of the physical signs of incipient phthisis is the broncho-vesicular breathing heard usually at the apex of the lung, and often best heard at the supraspinous fossa. The prolonged expiration heard in this region is significant, but care must be exercised that the blowing sound of the large air tubes be eliminated. With the broncho-vesicular breathing there is often associated a few crackling rales and a jerking inspiration, although the latter may be present when disease is absent. Percussion dulness and increased vocal fremitus are of very great weight as corroborative evidence of tuberculosis ; but the inability to detect either is of very little negative value.

Another very important element in the diagnosis is the microscopical examination of the sputa ; and here we come to the only pathognomonic symptom of incipient phthisis and that is in the demonstration in the sputa of the tubercle bacilli. The negative value of the absence of the bacilli is of but little weight, except on repeated examination of the sputa.

I will pass over the methods of staining and examination for bacilli ; also the symptoms of advanced pulmonary consolidation, and the stage of destruction of lung tissue with formation of cavities, and hasten to the no less important subject of treatment.

Prominent among the remedial agencies must be placed improved hygienic surroundings, a generous diet, and suitable climatic changes. A climate which permits of outdoor exercise the greatest number of days in the year is the one to which, in a general way, preference should be given. Where there is a tendency to hæmorrhages an elevated climate should be avoided, but under other circumstances an elevated climate, such as Colorodo affords, is preferable, inasmuch as the rarefication of the atmosphere necessitates a fuller expansion of the lungs, which, probably, tends to the reopening of the closed air cells. It may be well to sound a note of warning at this point on the folly of sending patients to another climate for the winter, in the hope that a permanent benefit will ensue. It seems to be a settled fact that patients who have been benefitted by such a change are under the necessity of remaining in the advantageous climate, as their return, except for a limited period, is fraught with the danger of a renewed outbreak of the disease.

Among the therapeutic agents may be mentioned cod liver oil, which may be said to be of value only in those comparatively few cases where it does not nauseate. The hypophosphites are doubtless of value, as are a score of other remedies. A favorite treatment of mine, and one which was chiefly used in the cases of the marines already mentioned, is the long-continued use of the following prescription :

℞

Hyd. chl. corr.	gr. j.
Ammon. chlorid.	ʒ ji.
Potas. iodidi.	ʒ jss.
Syr. pruni Virg.	ʒ iv.

M. Sig. One teaspoonful after meals and at bedtime.

The most remarkable remedy yet brought to light, and one which has made its already famous discoverer a household name in every home in the land, is Koch's lymph, or as it is more properly called, "tuberculin."

This remedy is the product of the tubercle bacilli. It is brownish colored liquid, is

exceedingly powerful, and is only used in the dilute form by hypodermatic injection, being inert if taken by the stomach. Now that the excitement following the announcement of the discovery has subsided and a considerable time has elapsed in which to test the value of the remedy, we may venture to give an opinion as to its merits and mode of action.

In order to understand the explanation given by Koch regarding the latter, it is necessary to speak a few words on the phenomena of coagulation necrosis, which is a peculiar change resembling coagulation caused by the action on the cells of a chemical product, or ptomaine produced by bacterial agencies. It is supposed that the casecation of a tubercular nodule is a condition of coagulation necrosis produced by the action on the tubercle cells of a ptomaine, the result of the growth of the tubercle bacilli. Koch reasoned that if he could add to the already ptomaine poisoned tubercular tissue sufficient of the same poison he could produce at will a coagulation necrosis of the living tubercular tissue, and thus place it in a condition to be either thrown off from the surface or removed by absorption. That this is the correct theory of the action of tuberculin I do not venture to express an opinion, but it explains in a satisfactory manner some of the phenomena observed in its use, such as the curious fact that the tubercle bacilli are not killed by the use of tuberculin, and that only living tubercular tissue is effected.

It is exceedingly difficult to give a satisfactory opinion as to the value of a remedy like this which has so many biased opponents and blindly enthusiastic advocates. What I have to say is the result of considerable attention to the voluminous literature of the subject, as well as personal observation of a great many cases under treatment in the hospitals of Berlin, and also about three months experience with the use of the remedy in this city.

In order to be brief, my opinions must necessarily be dogmatical.

Tuberculin is of considerable value as a diagnostic agent but is not always reliable, the reaction being often wanting in the surgical forms of tuberculosis and also occasionally in the pulmonary form.

As a rule the most marked benefits are obtained where the necrotic tubercular tissue can be thrown off from the surface as in lupus, tubercular laryngitis and tubercular ulcers.

Most cases of pulmonary tuberculosis in the early stages will be benefitted by the remedy, some to a very marked degree, so that a cure may be fairly claimed. Advanced cases of pulmonary tuberculosis where cavities have formed, and especially if the disease is rapid in its progress, are not likely to be benefitted, and will probably be injured by the treatment.

In the surgical forms of tuberculosis, tuberculin will be an aid to the operative treatment by assisting in the complete eradication of the tubercular tissue.

The nature of this paper restricts it within narrow limits. Many points upon which I would like to touch must be passed unnoticed, but I hope that this fact may, of itself, stimulate among the members a friendly criticism of the paper and a free discussion of tuberculosis.

C. S. Shaw, M. D., Vice President, in the Chair.

DISCUSSION ON TUBERCULOSIS.

THE TOPIC FOR DISCUSSION, "TUBERCULOSIS," WAS OPENED BY DR. R. W. STEWART. SEE PAGE 57.

Dr. T. C. Christy: I think the paper of Dr. Stewart concisely and accurately written. His experience is of value to all of us. I agree with him on his points on the physical diagnosis of tuberculosis. I believe that every physician is in duty bound to strip his patient and examine thoroughly; it is the only true way to examine a case. It seems to me that there is no better antibacillic material than pure blood; that is, there is nothing that will destroy bacilli so much as pure blood. Secondly, that the larger cells that we find in the blood vessels will destroy the germs, and keeping these two points in view, we have a basis of treatment which cannot be surpassed. We must follow the line of Dr. Stewart's plan of treatment, that it is pure air, hygienic surroundings and care that are most efficacious in treating this disease. Now going back to the idea that pure blood is the best germicide we have, anything that will induce the formation of pure blood will place these patients in their early years in a much safer condition than they would otherwise be; that is, in public school buildings and in

their daily exercise we can do much to prevent them from contracting disease. Another point which has lately been advanced by a French writer: He says that animals are more easily affected by bacillic injections where they have been deprived of food; or, in other words, that hunger will make persons more liable to contract this disease. Taking pigeons, which are not particularly susceptible to bacillic influence when deprived of food for several days, injections of the bacilli caused inoculation and death, whereas where they were well fed, they were free from the influence of the bacilli. I think if we are careful in the examination of patients, careful in the management of their case not to underfeed them and to look after their hygienic surroundings, we accomplish more than we can in any other direction.

Dr. Grube: One person in seven dies of tuberculosis, and I venture to say that one-half of the race have the germs of tuberculosis in their system. It is natural that a disease of such importance should command our careful attention. Our profession is exceedingly active in devising some means for the treatment of this disease. I think the greatest point, however, one which the speaker who has just preceded me brought up, is the early diagnosis and treatment of this disease. It is a disease of predisposition, and I believe that the ground work is laid in the embryo. I think here is the secret of the predisposition to tuberculosis. Dr. Trudeau, of New York, made some valuable experiments. He made an experiment with which doubtless many of you are familiar, and which will, I believe, become classic. He took fifteen rabbits and divided them into three lots. With the first five, he injected the pure solution of bacilli into their lungs, into the abdominal cavity, and under the skin of the neck. These five he placed in a dark cellar. The next five were inoculated in a like manner, and were turned loose on an island in the lake in the month of June, and they were fed with vegetables in addition to the vegetation upon the island which was accessible. The other five were not inoculated at all, but a hole was dug in the middle of a field; this hole was ten feet in depth and the remaining five rabbits, having been placed in a box, were lowered to the bottom of the pit. The box was covered with boards and dirt, a trap hole being left for the introduction of food. Of the first five rabbits, in the cellar, four died within a month, and all of general tubercular infection. This existed not only in the lungs but generally. The five in the pit were taken out perfectly well; they were emaciated, their coats were rough, but there were no signs of tuberculosis in any of them. Of the five which were liberated on the island, one died within a month; it had some tubercular affection of the lungs. The other four grew fat, and at the end of four months, were perfectly well and in fine condition; they were killed then, and not even the point of inoculation could be found; there was no sign of tuberculosis whatever. Now I think this is a lesson which can be made of practical use. Some one has said that the cause of consumption in London was that the poor were too poor to buy butter and fat, and the rich injured their digestion with too much pastry. What I want to bring out is the point that the rapid loss of weight in one who has this predisposition ought at once to call our attention to the fact that he is preparing the way for bacilli, and it is an open question whether in such cases the loss of weight is caused by bacilli or whether the ground is merely being prepared for them; I am inclined to believe that the latter is the case. Of course with a great many patients it is impossible to do very much. It is a matter of ability to bring the patient through the early stages of the disease safely. This means giving up a vocation which they cannot afford to give up. The question of occupation is one of the principal ones in this disease. Nearly one-half the printers die of consumption.

Dr. Buchanan: Dr. Grube's remarks call to my mind the theory proposed by that excellent pathologist, Dr. Formad, to the effect that tubercular individuals were such as had narrow lymph spaces, that it was the obstruction in the lymph spaces that caused tuberculosis, and he endeavored to prove this by microscopical measurements of the lymph spaces in different species of animals. I believe he made the same observations on human beings who were tuberculous, although I am not sure of that. I do not know whether Dr. Formad has endeavored to reconcile his theories with the modern views of tuberculosis as brought forward by Koch, but I believe that Dr. Formad's theory had its origin about the time that Prof. Koch discovered the bacilli of tuberculosis.

Dr. Bane: I have been in Colorado several weeks, and there met many people who had gone to that State on account of consumption, who went there expecting to die, but whose lives have been spared by reason of the climate, or you might say, by the air,

which is dry and light, especially when you go where it is so high as it is at Colorado Springs and Denver. As has been brought out by Dr. Stewart, in order to get sufficient oxygen more air is inhaled, the lungs are expanded and the cells which are not used in this district are employed there, and there is no doubt this is one of the reasons why those patients who have not a sufficient breathing space are so much better in that climate. It is a fact that many persons die in Colorado of consumption, but unfortunately they go there too late to be benefited; if they would go while in the incipient stages, certainly many of them would live to a good old age, but as a last resort many go there when they should stay at home, when they would live longer at home surrounded by home influences, than they do in the climate of Colorado, with all its advantages. There are many things to be said about sending a patient to Colorado. Persons suffering from heart disease fare badly in the climate on account of the rarity of the atmosphere; persons of a nervous temperament do not rest well there. I met there a friend, a neighbor of mine in the profession, who some six years ago went to Colorado Springs. He was told that it was not worth his while to go, that he would not live more than six months. However, he went, and began to improve from the time he reached Colorado. When he arrived there, his temperature dropped down to normal and there remained. He continued to cough for eighteen months. Then he thought he might come home to Philadelphia; he returned home, and after remaining some two weeks, his cough returned and he was obliged to once more go to Colorado, and on his reaching that place the second time it took him as long as before to become free from the cough and feel well again. He then learned he would have to remain in Colorado if he wished to live long. From Colorado Springs he went to Denver, where he has a good practice and good health. From his appearance I should think he weighs about 200 lbs. One physician who went there with consumption now weighs 300 lbs. Certainly we have patients here that we cannot expect to cure in this climate that we are not justified in keeping here if they have the means to take them to a climate such as exists in Colorado. This is the impression made upon me after visiting the State and meeting these people. True, they have to remain there, but it is no punishment to live in Colorado, where they have as fine a climate as I have ever seen, and where eastern people, with eastern business and social ideas, form the bulk of the population.

Dr. Rigg: I was much pleased with Dr. Stewart's paper. I think it deserves our careful consideration, and there are many points in it that would bear further investigation. The doctor's calling attention to early diagnosis is a very important thing, also, the natural tendency or the inherited condition. The doctor stated that tuberculosis is not an inherited disease, which fact is well established at this time. The predisposition, however, is inherited. We have it in the animal the same as in the human family. You take the rabbit and the guinea pig they are naturally tuberculous; the dog and cat are naturally non-tuberculous; the rat is not naturally tuberculous. Now, you take a family of children coming into the school-room, and it is a comparatively easy matter to see which are tuberculous children. The conditions under which they have been reared may have had much to do with developing the condition. I am not sure that nationality has not something to do with it. Six or seven years ago, I made some little investigation on that line. This investigation of mine was conducted through the southern part of Westmoreland county, and the northern part of Fayette, and covered a period of three years. I suppose in all I collected statistics from 150 different families. In regard to the investigation of Dr. Formad, it was my pleasure to be with him a part of the time he was making the investigation. He took the children in the hospital and held *post-mortems* there and examined some of the tissue from all children who were believed to be tuberculous yet had sickness and died of acute diseases, and also from children who had died of tuberculosis. He examined the connective tissue from other children that had died that we believed to be non-tuberculous. and there was a marked change, a marked difference in the lymph channels that fully convinced me that there was more in it than mere theory.

My recollection is that he had modified his views at that time greatly with reference to the cause of the bacilli. He admitted that the bacilli might be the carrier of tuberculosis, and that it might possibly be the specific poison.

The question not settled in my mind is this: are the bacilli, as a rule, one of the early evidences of tuberculosis? Take a subject that is predisposed to it, that has, if you please, the narrow lymph channels, and will you not have a certain amount of engorgement in the lungs before the bacilli? In other words, are the bacilli present before

there is inflammation, or are the bacilli formed subsequently to the inflammation? In regard to the influence of surroundings that has been referred to by both the gentlemen who have spoken. An experiment was made on rats, I do not recall the particular poison that was used, but it made an impression on my mind. A number of rats were caught and kept under favorable conditions; they were injected with specific poison and turned loose in comfortable circumstances under hygienic surroundings. Others were put in a treadmill, where they were obliged to work and kept at it until they were tired. They sickened and died with tuberculous disease. The first lot lived and thrived. But that is only one evidence of many that pure air, pure food and pure surroundings fortify the system against the attack of any disease; I do not care whether it is tuberculosis or something else; if there is a special tendency to tuberculosis, it will likely be that; if there is a tendency to something else, it will likely be that. In regard to the influence of a rarefied atmosphere; I think there is a good deal in that, and we might see why, if we bear in mind the fact, that the apex of the lungs is the portion usually involved first. It is, perhaps, the portion of the lung least used under ordinary circumstances; expansion is less there than at any other portion of the lung.

I have nothing to say as to treatment. In regard to the tuberculin it seems to me that the theory on which it is given will hardly bear us out in using it constantly. I think it is a step in the right direction, yet the question that comes up in my mind is whether or not you can generate a poison from the bacilli that will do what is claimed for the lymph, or that will aid nature in throwing off the diseased tissue. It seems to me we cannot expect much on that theory. As far as I am personally concerned, I want to see some more rational theory advanced or else more satisfactory experience. I have two cases on hand now, and for a month I have debated in my own mind whether or not to advise a trial, and I have not had the courage to do it. The patients are willing and ready to take the risks if so advised, and if there can be anything that will help me to decide, I would be very glad. One of them is a case of tubercular trouble, pulmonary tuberculosis, and the other is a case which Dr. Buchanan saw with me six weeks ago, tuberculosis of the lymphatic glands and the ankle joint.

Dr. Stewart: As to the doctor's remarks in regard to Colorado. A patient came to my office from Colorado recently; he had returned to this city and gone to work. I examined his lungs and found marked consolidation of the upper portion of both lungs. I told him to go back to Denver as soon as he could. I do not think I could have done him any good. With regard to Dr. Rigg's question as to whether the bacilli are present at the early stage. My understanding is that the presence of the bacilli is an essential factor at the initial stage of the disease, and that the tubercular products are the result of the growth of the bacilli.

I would speak a few words of my own results in the use of Koch's lymph. The first case was for diagnostic purposes on a patient in the Mercy Hospital, but he left before a result could be ascertained. The second and third cases were in St. Francis Hospital; both cases were confined to their rooms and the disease was progressing rapidly, both improved at once and have since left the hospital, although still continuing under treatment, and their improvement still continues. The remaining cases were treated in Mercy Hospital; one advanced consumptive did not improve and has since died. Another remained two weeks in the hospital with but slight improvement, but continues the treatment at his home, and is steadily improving. A case of destruction of the nose supposed to be lupus, did not give any reaction even to a dose of twenty-six milligrammes, and was not benefited. I considered the condition as that of an epithelioma. A case of lupus of eyelid at present under treatment gives promise of a cure.

HÆMORRHAGE AFTER LITHOTOMY.

Dr. J. W. Macfarlane: On the 15th of last April, assisted by Dr. Small and the residents of the Western Pennsylvania Hospital, I did a left lateral lithotomy upon Jas. Mehen, removing a mulberry calculus weighing six drachms.

The history of the case is as follows: The lad is sixteen years of age and undersized. His trouble dates back to last July, when he moved to, and secured employment, in Kittanning. The pain and vesical irritation that began to bother him soon after his advent in the place, he attributed to the drinking water, which, he thought, did not agree with him.

In spite of some treatment, his symptoms steadily grew worse during the fall and winter months, when he finally presented

himself to Dr. Thos. McCann, who sounded him and discovered a stone in the bladder. He was sent to the West Penn Hospital, and I operated upon him as before stated.

No trouble was experienced at the time of the operation; there was some bleeding, but no more than is usually seen; the stone was extracted slowly, and the bladder carefully washed out. I saw the patient about half an hour after the operation, and, though I did not examine the bed, I felt the boy's pulse, and left him thinking all was well. About fifteen minutes after this the nurse noticed that he was bleeding freely. Dr. C. B. King, who happened to be at hand, introduced an umbrella-shaped tent into the wound, a catheter forming the center of the tent, and oil silk the outer, the space between the silk and the catheter being packed with cotton. This seemed to arrest the hæmorrhage for a time, but the presence of the catheter and clot in the bladder produced irritation, constant straining, with expulsion of the tent, and a return of the hæmorrhage.

Between three and four o'clock, some three hours after the operation, Dr. King having gone home, I was summoned to the hospital, and on my arrival found my patient with head down and feet elevated; he was pale, sweating, vomiting, thirsty, with a rapid pulse, and in anything but a promising condition. I examined the wound, but was unable to find the source of hæmorrhoge. I removed some clots from the bladder, tried to introduce a fresh tent, but the attempt at introduction produced so much straining that I immediately abandoned it.

I then slipped a piece of gauze, well oiled, over my index finger, introduced it into the wound, and, withdrawing the finger, packed the space as well as possible with absorbent cotton; but this did not arrest the hæmorrhage, the oozing still continuing. The irritation of the bladder being so great as to preclude the introduction of anything within its walls, we concluded to flush the intestines with hot water, and see what effect that would have.

A flexible rectal tube was introduced well up to the sigmoid flexure of the colon, and a large quantity of hot water forced into the bowel. The rectal tube was withdrawn, a pad placed over the rectum and tent (which had been held in position) with a **T** bandage over all. I am happy to say that the effects of the hot water were soon made apparent, the pulse improved, and the hæmorrhage was arrested.

At eight o'clock that night the patient had reacted; there being odor of urine in the bed, the pads were not removed until the following morning, when they were discontinued. Dr. Todd, the resident in charge, kindly sat up with the boy the first night, giving him hypodermic injections of whisky or aromatic spirits of ammonia when required.

The patient, though weak for a time, made an uninterrupted recovery from this on, being absolutely free from pain. On the 28th of April he passed water through his urethra. On the 29th he passed a minute fragment of stone, evidently one of the small points which you will see is missing in the specimen.

The boy was discharged from the Hospital perfectly well on the 15th of May, one month after treatment.

It is probable that the vessel from whence the bleeding came was injured during the extraction of the stone, which is studded with sharp points, as you see, and that it gave way at the time or a short time after the patient was lifted into bed.

Dr. Buchanan: It was my fortune, six years ago, to assist Dr. Kersey in a similar case. At St. Francis Hospital he removed a very large stone through an incision which was probably of necessity insufficient. At all events, there was a great deal of trouble in removing the stone, and, although there was no hæmorrhage at the time, there must have been considerable contusion of the tissues. If I recollect aright, on the sixth day a very severe hæmorrhage came on. Dr. Kersey was sent for late in the afternoon, and I went with him to assist in checking the bleeding. We tried all the ordinary means to stop the hæmorrhage, endeavoring first, of course, to secure the bleeding vessel. The man seemed to be at the point of death, and we were not long in trying the umbrella catheter; but in this instance, at least, it was a dismal failure. A sufficient pressure could not be exerted. We then passed a catheter of considerable calibre as far as the bladder, and put two or three sponge-tents along side of it. The bleeding was instantly checked, and the man recovered.

Dr. Stewart: I have had two cases—one hæmorrhage from rupture of the urethra; there had been several attacks of hæmorrhage, the patient becoming very faint. When I saw him he was bleeding, and there was an opening in the perineum, which had been made to relieve the extravasation. The hæmorrhage was checked by plugging around a silver catheter placed in the perineal opening. The second case was similar to the

first, except that the hæmorrhage was caused by ulceration from prolonged pressure of a silver catheter against the margins of an exploratory perineal opening. The hæmorrhage was checked in similar manner to the preceding case.

SELECTED FORMULÆ.

HERPES ZOSTER.

INTERNALLY.

℞
Ext. gelsem. fl.....3i.
Sod. sulphocarbolat.....3i.
Aquæ q. s. ad.....3iij.

—Matthew Beattie, M. D., in New York Medical Record.

FLATULENT DYSPEPSIA.

℞
Magnesia.....
Calcium phosphate.....
Powdered charcoal.....
Sulphur. .....aa p. ac.
A teaspoonful to be taken in water when necessary.

—Provincial Med. Jour.

BALDNESS.

In falling of the hair, a writer in the *Lancet* recommends the following, a little to be rubbed on every night:

℞
Tinct. jaborandi.....3 iv.
Lanolin.....3 iij.
Glycerin.....3 ij.
Mix with the aid of a little soft soap.

TREATMENT OF GOUTY PAINS OF THE GREAT TOE.

The following application should be frequently painted over the painful toe:

℞
Collodion.....5 grammes.
Ether.....5 grammes.
Salicylic acid.....4 grammes.
Muriate of morphine.....1 gramme.
M.

—Journal de Médicine de Paris.

SUBNITRATE OF BISMUTH FOR INFANTILE ECZEMA.

The following is recommended by the *Journal de Méd. de Paris*, May 24, 1891, in the treatment of infantile eczema:

℞
Subnitrate of bismuth.....20 0 grammes.
Oxide of zinc..... 5.0 grammes.
Carbolic acid..... 2 0 grammes.
Vaseline.....30.0 grammes.
M. Sig. Salve, to be rubbed in over the affected parts.

If the itching is severe, the following application will be found of great value:

℞
Subnitrate of bismuth..... 5.0 grammes.
Glycerin.....20.0 grammes.
Carbolic acid..... ... xij gtt.
Rose water.....30.0 grammes.
M. Sig. Shake well, and apply to the affected parts with a soft brush.

TERPINE AND ANTIPYRIN IN THE TREATMENT OF WHOOPING COUGH.

Dr. M. Talamon, in a recent number of the *Medizina*, states that he has found terpine, associated with antipyrin, a most efficacious remedy in whooping cough. He uses the drug in the following formula:

℞
Hydrate of terpine.....1 to 1.50 gramme.
Antipyrin..... 1. gramme.
Syrup of orange-peel..... 50. grammes.
Tolu water..... 60. grammes.
M. Sig. One-half to one teaspoonful several times a day, for children from one to four years of age.

HYPODERMIC INJECTION FOR TUBERCULOSIS.

Pignol, in the *Journal de Méd. de Paris*, May 31, 1891, recommends the following hypodermic injection for the treatment of tuberculosis:

℞
Eucalyptol.....0.14 grammes.
Gaiacol..... .....0.05 grammes.
Iodoform.....0.01 grammes.
Sterilized olive oil, q. s., ad. 1 cubic centimetre.

The daily dose should vary from 3 to 10 or 12 centigrammes.

ECZEMA.

The following is highly recommended for eczema in children:

℞
Bismuth subnit.....3v.
Pulv. zinci oxid.....5j.
Acid carbolic.....gtt. xxx.
Vaseline.....3i.
M. S. Rub thoroughly into the affected parts.

When much irritation is present employ the following:

℞
Bismuth subnit.....3i. gr. xv.
Glycerin..... .....3v.
Acid carbolic.....xij gtt.
Aquæ rosæ.....f3i.
M. S. Shake well and apply with a soft brush.

—Nouveaux Remedes.

THE

MEDICAL AND SURGICAL

REPORTER.

ISSUED EVERY SATURDAY.

EDWARD T. REICHERT, M. D.,

PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF PENNA.,

EDITOR AND MANAGER.

N. E. Cor. 13th and Walnut Streets,

P. O. Box 843. Philadelphia, Pa.

THE MEDICAL AND SURGICAL REPORTER.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent 3 months on trial for $1.

At the termination of the period of subscription, we will promptly discontinue sending THE REPORTER unless directed to the contrary by the subscriber.

Remittances should be made by draft, check, postal note, or money order payable to Edward T. Reichert.

THE POCKET RECORD AND VISITING LIST.

Two sizes. Prices to subscribers of THE REPORTER: For 30 patients a week (with or without dates), $1.00. For 60 patients a week (without dates), . . $1.25. Prices to non-subscribers, $1.25 and $1.50 respectively.

THE MODEL LEDGER.

Physicians who keep their own books will find this of great value. Sample pages sent on application. Price, $5.00.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If THE REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS.

Write in ink.

Write on one side of paper only.

Write on foolscap or legalcap paper.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be pleased to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

LEADING ARTICLE.

ELECTRICAL INDUCTION AS A GERMICIDE.

In the experiments of various investigators of recent date, the attempt has been made to destroy micro-organisms by the application of some physical force. Foremost in this line are the experiments of Koch, and his pupils, with heat; who have made a most extended and exhaustive series of experiments.

D'Arsonval and Dubois have, in the meantime, turned their attention to magnetism, while Cohn and Mendelsohn have carefully tested the effect of the galvanic current upon the life of microbes. In galvanism, however, the results can very possibly be said to be due to chemical action, the current changing the nature of the fluids with which it comes in contact, and transforming them into germicides. According to the majority of investigators, a specific action of the galvanic current cannot be proven.

Recently, Drs. Spilker and Gottstein, of Berlin, have been experimenting with a method as yet untried by other investigators, and in which the simultaneous actions of other forces, either caloric or chemical, is absent, as are also the changes which might be produced by electrolysis.

The force used by Drs. Spilker and Gottstein, has an electrical induction current, the experiments being conducted in the following manner. The fluid containing the culture was placed in a glass test-tube wound about with a wire coil, through which an electrical current, either from a dynamo or from accumulators, was allowed to pass. Subsequently, vessels of clay were used in place of glass test-tubes. The electrial current did, indeed, produce some degree of warmth in the substance which was being tested. The increase of temperature thus produced never, however, exceeded 36.6° C.

Experiments were first made with the *micrococcus prodigiosus*, cultures of which were floated in water. This mixture was treated with a current of 2.5 amperes + 1.25

volts. The treatment lasted for twenty-four hours, during which time the temperature of the mixture never went above 30° C. The results showed that complete sterilization had been effected. However, the destruction of the micrococcus prodigious by induction could only be accomplished when the cultures were floated on or mixed with water. Gelatine or agar cultures were unaffected by the current. Various nourishing substances were added in other experiments to the watery mixture, but in this case, as in the first, the mixture was rendered sterile by the current. Other micro-organisms were tested with similar results.

The experiments, therefore, justified the conclusion that in mixtures of micro-organisms with water, the electrical current produced by induction was able to destroy the micro-organisms after a certain time.

The same results were, however, not obtainable with micrococci in milk, although the current seemed to delay the development of the bacteria in this medium for several days, and the number of colonies would also decrease. Beer (Weissbier) gave the same results as water.

Regarding the strength of the current, from 10 to 12 amperes were used in tubes of 3.5 centimetres in diameter. The duration of the current is a most important feature. In treatments lasting only one hour sterilization was never obtained, there being only a decrease of the number of germs, but no weakening of their activity.

Further experiments showed that when the water containing micro-organisms was agitated during the treatment the action of the current was quicker than when the mixture was undisturbed. The hopes expressed by the authors in their article in the *Centralblatt fur Parasiten-Kunde*, viz., that their method would find practical value in the sterilization of water supplies, were not realized, inasmuch as the application of a current for a continued time would involve too great a cost.

The action of the induction current upon micro-organisms in the blood, was more favorable even than that in water. In a comparatively short time pathogenic micro-organisms can be rendered innocuous by such a current. Blood and water, containing pathogenic germs, were rendered sterile by the induction current in from five minutes to a half an hour. Subsequent inoculation of mice with this mixture thus treated proved it to be absolutely innocuous. The authors were of the opinion that the iron in the blood played an important part in the results, since the induction current and magnetism are so closely related. Acting upon this thought, they added to the mixtures various salts of iron. While the sulphate, lactate and citrate, seemed to produce no change, the albuminate of iron exerted a most powerful influence.

If solutions of 1:1,000 of albuminate of iron were added to a watery mixture of micro-organisms, a current lasting only ten minutes would cause a sterilization which would last for eight days. After this time, however, colonies would slowly form.

Spilker and Gottstein believe that this action of the albuminate of iron is due to what Pfeffer and Buchner designated as a *chemotactic* property of certain micro-organisms.

At all events, their experiments show that with the addition of albuminate of iron to organic fluids or tissues, we have in electrical treatment by induction, a valuable agent, capable of suspending or checking the production of micro-organisms.

The therapeutic value of these experiments remain yet to be tested. Their hygienic value is, however, very evident, viz., the preparation of various foods or drinks; and it is with this subject that the authors are at present at work. Already they have shown white-beer (Weissbier) treated by electricity will keep much longer than beer not so treated. Butter also, after being treated, will preserve a fresh appearance and taste for weeks. The untreated butter, at the end of two weeks, was found to contain 30 per cent. more of free acid than that which had been subjected to the current.

The action of the current on fluids out of the body and on those in the living organism

are totally different. While in the former instance the current may be active, in the latter it is valueless. Inoculated mice were placed in clay tubes, but even a prolonged application of the current produced no result. Even when the wire was wrapped directly around the vessels of the animal the effect of the inoculation proceeded unchanged, and would finally cause the animals' death.

Perhaps the many fervent advocates of electrolysis in gynæology may find some food for thought in these experiments, which are surely of more than ordinary interest, and may very possibly result in a better understanding of the value of electricity in therapeutics, especially so in the treatment of tumors.

Book Reviews.

FEVER—ITS PATHOLOGY AND TREATMENT BY ANTIPYRETICS. By Hobart Amory Hare, M. D., B. Sc. Philadelphia and London. F. A. Davis, 1891.

This work has already attained some reputation, being the essay to which was awarded the Boylston Prize of Harvard University in 1890, its title at the time of presentation to the Committee being The Uses and Values of Antipyretics.

As the author says in his preface, "it would be difficult to find any theme about which so much has been written in the past ten years as the subject with which this essay deals," and yet we know of no one work in which the results and conclusions obtained by so many of the best observers are so concisely summed up as here. Not only has it been the author's aim and duty "to gather up the good grain from the tares rather than to bring before the readers for his examination the entire crop of communications as a garnered harvest," but he has added accounts of a number of his own experiments, which help to clear up doubtful points about the drugs under consideration. Points of especial interest to the practising physician will be the study of the pulse tracings, the tables showing the cases in which untoward effects have occurred from the use of the various antipyretics, and the chapter in which the author gives a comparative summary of the practical value of the different agents for the relief of different conditions or symptoms. It will surprise most reades, no doubt, to find how rarely fatal effects have occurred from the use of modern antipyretics, though often "the symptoms seemed to be severe."

The book is in Dr. Hare's best style and will be eagerly read by any one who begins its perusal.

THERAPEUTIC HANDY REFERENCE BOOK FOR PHYSICIANS—WM. R. WARNER & CO., PHILADELPHIA. 1890.

This little book, well termed "handy" and now in its third edition, with several additions and improvements over previous ones, contains much information useful to physicians. Commencing with a table of weights and measures, arranged in both English and French terms, it continues with a short talk upon prescription-writing, an extensive posological table which gives also the physiological action in brief of each drug. Succeeding this are a few generalizations intended to aid the memory for the doses of the various preparations, and then some directions regarding hypodermic medication, with formulæ. "Incompatibilities." "Poisons and their Antidotes." Marshall Hall's Method of Artificial Respiration," "Signs of Pregnancy," and a table of the digestibility of foods, as well as one for calculating the duration of pregnancy, follow in the order given. The book ends with "Directions for making post-mortem examinations," and numerous medical formulæ.

Thus, as has been said, the book is filled with useful information, and will doubtless be of value to many physicians, as a compact and ready reference pamphlet.

TREATMENT OF SYPHILITIC ULCERATIONS.

Plumert gives the following applications for ulcers of syphilitic origin:

℞ Mercury salicylate.....xv gr.
Potassium carbonate.....xv gr.
Distilled water.....℥vj. M.
Dissolve. Sig. Wet compresses with this solution and apply to the ulcerations.

If an ointment is preferred, recurrence may be had to the following:

℞ Mercury salicylate..... xv gr.
Vaseline.....℥ j.
M. and make a pomade.

PERISCOPE.

THERAPEUTICS.

A NEW TREATMENT OF HYSTERIA.

Of all diseases of the nervous system that which the physician meets most frequently is hysteria. It has been the custom to look upon this disease as something rather mental than physical in its character, to suppose that the victim was not diseased as much as shamming, so much so that the laity has come to regard the diagnosis of hysteria almost as an insult—an indication of a feeble mind. He would, nevertheless, earnestly protest against such a misconception. There can be no question that in hysteria we have to deal with a physical disease, and not an imaginary malady. Its symptoms may be divided into two distinct groups: (1) the mental; (2) the physical; and their severity may be entirely out of proportion to each other. In one case the mental signs may predominate; whereas in another almost none of the mental peculiarities we usually encounter may be present, and only a careful physical examination may lead to a proper diagnosis. Hysteria depends upon a condition of increased irritability of the entire nervous system, involving the brain, the spinal cord and the sympathetic. The result of this is that causes which under normal circumstances produce only a slight or transitory effect, lead to more or less permanent manifestations.

All the symptoms of hysteria are met with in a far less developed form in healthy individuals under certain conditions. It is evident that laughing and crying so often seen in the hysterical, is simply an exaggeration of that condition in the normal. The paralyses of hysteria even have their analogy in the inability of speech or to move, occurring under the influence of severe emotion, and the convulsion of hysteria is only an exaggeration of the tremor that we see ordinarily associated with fear and anger. The peculiarity of the hysterical subject lies in the excessiveness of the reaction. What causes this increased irritability is unknown, but it must be some anatomical change even if only a molecular one. Whether that alteration be seated in the entire nervous system, or whether it be located in the sympathetic, that unexplored accessory system, we do not know. That the sympathetic may play a more important role than has hitherto been proven is by no means improbable, and he leaned to that interpretation of the etiology of the disease. So many of the signs of hysteria are associated with secretory and vasomotor changes, and so many can be explained by unilateral vasomotor changes in the brain, that this theory is quite seductive.

It is one of the peculiarities of hysterical paralyses that they are unilateral, involving the upper and lower extremity, but leaving the facial nerve intact, that they are accompanied by anesthesia, but involving the head and face as well, not only of the skin, but also the special senses—hearing, sight, smell and taste. At the posterior portion of the internal capsule, between the lenticular body and the thalamus opticus, we have all the fibres collected that supply these parts, the facial nerve running more anteriorly. This region is supplied by the anterior choroid artery, a branch of the middle cerebral not anastomosing with other vessels. The anterior part of the internal capsule is supplied by the posterior communicating artery, drawing its blood supply from the carotid and basilar arteries through the posterior cerebral. A vacomotor disturbance which would cause a marked anæmia in the territory of the anterior choroid artery could not do so in that of the posterior communicating. Hence a paralysis due to anæmia arising from arterial spasms would not effect the latter region, and the facial nerve would not be disturbed. This was probably what occurred in hysteria, and was a very strong argument in favor of the speaker's opinion that hysteria is due to a lesion of the sympathetic nerve. [The speaker here domonstrated a brain in which the anterior choroid artery had been injected with carmine, showing the posterior portion only, of the internal capsule, red.] It has been rightly held that in this disease from alteration of the sympathetic nerve, a spasm of the arteries in certain parts first occurs, followed by a relaxation with œdema, the latter making the symptoms so permanent. We see the same œdema in hysteria in various parts, and a special form of it occurring in the hands and attended with cyanosis, has been lately described by Charcot as the blue œdema of hysteria.

The speaker desired to direct attention to some of the phenomena which may have escaped notice that are of great importance in making the diagnosis, and in determining whether or not the disease has been cured. These interesting symptoms are the sensory. If you examine a typical case of hysteria, you will find that the sensibility to pain, as the prick of a pin, is entirely lost on one side and that the disturbance is sharply cut off at

the median line, whereas, on the other side, the slightest prick is painful. This analgesia involves one-half of the head, neck and trunk, and the upper and lower extremity on that side, and you will also observe that the puncture on the analgesic side does not draw blood. You may find the sense of touch, pressure and temperature defective, and hearing, smell and taste may be entirely absent on the same side. In examining the eye, very peculiar symptoms are likely to be met. There is frequentiy a contraction of the field of vision in both eyes, but usually more marked upon the side upon which the sensory disturbances are found. The contraction is uniform in all parts of the field of vision. This contraction may become so great as to produce complete blindness. Another anomaly of the hysterical eye is the disturbance of color vision; the sensibility of the retina to various colors may become seriously involved, leading to complete color blindness.

A further peculiarity of hysteria is the presence of certain zones which are hyperesthetic, and pressure upon which brings forth either a complete hysterical attack, or some of its signs. The most frequent position of this hysteriogenic zone, as it is called, is the lower lateral abdomen, that termed the ovarian region. Pressure here is almost invariably sensitive in case of hysteria, and this is true of males as well as of females, proving that the ovaries have nothing to do with the symptom. For convenience it is called ovarian tenderness, but is probably produced by the sensibility of the sympathetic nerves, which are so generously distributed in that region.

Acting upon this fact, and influenced by his belief that the sympathetic is the seat of the hysterical lesion, the speaker has applied the constant current to that region in the treatment of that disease, and had met with most flattering success. Feeble currents had at first been used, but in this, as in other diseases of the nervous system, it was soon found that large doses are necessary. He had used currents from 20 to 60 milliamperes, applied for about five minutes. One pole high up the back, and the other, usually the negative, to the sensitive ovarion region. The electrodes were 6x12 cm. in size and thickly stuffed with compressed moss. In order to make it impossible to employ these strong currents, he used a very delicate rheostat, with resistances from 0 to 200,000 ohms, which enabled him to turn the current on and off so gradually that there was no shock, and permitted the use of strong currents without pain.

In nearly every case, the effect was an immediate improvement in all of the symptoms after very few applications, and, in the vast majority, complete cure, not followed by relapse. That the cure was due to the physical action of the electricity, and not to the imagination of the patient, he proved by the fact that in many instances he led the patients to believe they were taking electricity, whereas, no current was passing, and, in every such case, no benefit resulted from the imaginary treatment. He considered only those cases cured in which the subjective symptoms of despondency, *globus hystericus*, weight of the chest, numbness of the extremities and hysterical attacks had disappeared, and in which analgesia, loss or impairment of the special senses, and sensibility of the ovarian regions could not be found.—*Occidental Med. Times.*

TURPENTINE AS A GERMICIDE AND ANTISEPTIC.

Dr. W. Schleppegrell, in the *Medical News*, says, although the oil of turpentine (*Oleum Terebinthinæ*, U. S. P.) is not unknown as an antiseptic and germicide, its insolubility in water and its irritating properties have hitherto made its use impracticable. That it has its special uses, however, in this connection I have had abundant testimony.

It is a well-known fact among naturalists, that, if the air of a cabinet be impregnated with the vapor of turpentine, the specimens are safe from the ravages of moths and other intruders so long as this condition of the air of the cabinet remains.

Having learned the advantage of turpentine in preserving entomological specimens, I concluded to try its germicidal properties in the cases containing surgical instruments. A bacteriological examination of the cases, made four weeks afterward and compared with the examination of cases not provided with turpentine, convinced me of its efficiency, and I soon afterward applied the same principle to drawers containing towels, gauze, bandages, etc.

The method is simple. The turpentine is placed in flat, large-mouthed bottles at the bottom of each case or drawer, the volatility of the turpentine causing the vapor to impregnate the surrounding air.

Of late I have also placed my surgical instrument, the night preceding an opera-

tion, in a flat dish containing oil of turpentine. The instruments are completely sterilized, are not injured by the submersion, and are easily dried by a piece of sterilized gauze or towel. The characteristic odor of turpentine can be removed by ether.

The cheapness of turpentine and the ease with which it may always be obtained, added to its special adaptability in preserving the aseptic condition of instruments, bandages, etc., by its vapor, may make it a valuable addition to the list of our antiseptics and germicides.

I have also used benzole in the above manner. Its greater volatility gives it a more rapid germicidal action than turpentine, but its great inflammability admonishes caution in its use.

POISONING BY BELLADONNA PLASTER.

Mrs. W., aged 23 years, was confined four months ago. The baby was nursed till three months old, when it was thought advisable to "dry the breasts." The patient applied belladonna plasters to the breasts, and she was told not to interfere with them till they fell off themselves. Being on a visit to friends and not feeling well, she was brought to see me on February 28th. She was very pale and anæmic, complaining of frontal headache, dimness and haziness of sight, dryness of mouth and throat, thirst, and loss of appetite. She remarked that her breasts were sore, and that there was a disagreeable smell proceeding from them. On examination I found that she had two filthy sodden plasters on her breasts. When these were removed the skin presented a well-marked pustular eczematous condition over the area covered by the plasters, from which a very offensive odor of decomposing matter emanated. Over the arms and forearms on both extensor and flexor surfaces and over the front of the knee-joints, the lower fifth of the thighs, and the upper fifth of the legs there was a rash of a distinctly uticarial type, attended with considerable itching. The pupils were widely dilated. The breasts were ordered to be bathed with hot water, and then smeared over with vaseline. I saw the patient on March 3rd, and found all the symptoms quietly subsiding.

Amongst the frequenters of out-patient departments it is no unusual thing to see these offensive plasters on the breasts. Far more efficacious and cleanly applications are the liniment or the extract of belladonna rubbed up with glycerine, the breasts to be carefully bathed with hot water night and morning. In cases of pleurodynia and myalgia these applications, when rubbed into the skin, besides being cleaner, give more immediate and permanent relief than the plaster on account of the accompanying massage.

Dr. P. Rhys Griffiths, in *Brit. Med. Jour.*

BROMOL.

This is the name recently given to the well-known compound, tribromophenol, which is produced when phenol or carbolic acid is treated with an excess of bromine in aqueous solution. It has been found to possess strong antiseptic properties, and to be, at the same time, non-toxic.

Rademaker has recommended it for external use, either dissolved in olive oil (1 in 30) or mixed with vaseline (4 in 30). It may also be applied in form of powder, like iodoform, for sprinkling on wounds. In diphtheria or angina due to scarlatina, the throat may be touched with a solution of 1 part of bromol in 25 of glycerin.

The same author has used the substance internally in doses of $\frac{1}{12}$ to $\frac{1}{4}$ grain, in cholera infantum and typhoid fever with success.—*Chem. Centralbl.*, No. 21.

A CASE OF POISONING BY CAMPHOR.

Dr. Sydney E. Atkins, in the *Brit. Med. Jour.*, says, he called one day to see C. A——, aged five, who, he was informed, had swallowed some spirit of camphor. On arrival, he found the child lying on the sofa deeply convulsed, pupils widely dilated, pulse 120, very weak and small, extremities very cold and face livid. From what he could gather, about two and a half or three drachms of spirit of camphor had been taken, which would represent about fifteen or eighteen grains of the pure drug. He immediately gave an emetic of mustard-and-water, followed by, as soon as he could obtain it, half an ounce of ipecacuanha wine. This produced vomiting of lightish brown fluid, having a strong smell of camphor. Hot flannels were applied to the feet, and as soon as the vomiting ceased two teaspoonfuls of castor oil were administered. The patient made a rapid recovery, with the exception that for the next two or three days she complained of nausea and pain in the epigastrium, and was unable to retain anything in the stomach but a little beef-tea or soda-and-milk. This he attributed to a slight attack of gastritis.

MODERN DERMATOLOGICAL REMEDIES.

The following information respecting some of the newer forms of external remedies used in the clinic of Professor Hebra, Vienna, is published in the *Pharmaceutische Post:*

Spray Treatment.—Very frequently an ether spray is used as a vehicle for mercuric sublimate (1 to 2 per cent.) and chrysarobin (10 per cent). It is considered that the spray, besides its anodyne properties, presents the advantage of attacking affected parts otherwise difficult to reach, such as those covered with hair. Whilst the mercuric chloride spray does good service, principally in affections of the mucous membrane, the chrysarobin spray is used in mycosis of the skin. The apparatus used is one combined with a ball blower.

Medicated Soaps.—The superfatted medicated soaps introduced by Unna are used in a form as improved by Eichhoff. The basis consists preferably of beef tallow, together with Liquor sodæ two parts, Liquor potassæ one part, and some olive oil. The superfatted soaps employed are the resorcin-salicylic, resorcin-salicylic-sulphur, resorcin-salicylic-sulphur-tar soaps. In these forms the resorcin is claimed to develop advantageously its action antagonistic to inflammation; the salicylic acid is said to dissolve the horny layer of the epidermis and to act as a bactericide; the sulphur also lowers the inflammation; while the tar diminishes the itching and favorably influences the dilated vessels.

Glycerinum Saponatum.—This is an ointment basis, containing a large proportion of glycerin, in the preparation of which a small quantity of a neutral cocoanut-oil soda soap is used. Its composition varies from 80 to 92 per cent. of glycerin and 20 to 8 per cent. of soap. The glycerinum saponatum is soluble in cold and warm water, and is said to possess the advantageous property of dissolving a large number of substances, and of holding other insoluble pulverulent substances in suspension. To this class belong:

A. Ointments with an Acid Basis (80 per cent. glycerin).—(1) Glycerinum saponatum with salicylic acid (5 per cent,), employed especialiy for the removal of horny epidermal growths; (2) Glyc. sapon. with salicylic acid (5 per cent.) and resorcin (5 per cent.) combines the properties of the preceding with those of resorcin in diminishing the inflammation, acting as an antiseptic, and promoting the regeneration of the epidermis; (3) Glyc. sapon. with salicylic acid (5 per cent.) and creosote (5 per cent.) promotes healing without pain in lupus vulgaris, lepra, etc.; (4) Glyc. sapon. with salicylic acid (3 per cent.) and tar (10 per cent.), useful in scaly eczema with itching.

B. Ointments with a Neutral Basis (92 per cent. glycerin).—(1) Glyc. sapon. with zinc oxide (5 per cent.), used for cosmetic purposes and in slight cases of eczema; (2) Glyc. sapon. with sulphur (10 per cent.); (3) Glyc. sapon. with zinc oxide (10 per cent.), used in acne; (4) Glyc. sapon. with iodoform (5, 10, to 50 per cent.), said to be remarkably active, purifying and promoting granular action in wounds, ulcers, buboes, and carbuncles; (5) Glyc. sapon. with chrysarobin (10 per cent.), approved especially in psoriasis; (6) Glyc. sapon. with hydroxylamine (1 per cent.), used in psoriasis of the face and hairy scalp; (7) Glyc. sapon. with ichthyol (5 per cent.) renders good service in violent itching of skin affections and arthritic swelling of the joints; (8) Glyc. sapon. with ichthyol (10 per cent) and zinc oxide (10 per cent.), as in the preceding, and in incipient eczema; (9) Glyc. sapon. with carbolic acid (2 to 3 per cent.) is good for disinfecting the hands and also to relieve itching.

In other cases the vehicle represents a kind of dressing. Among the *Pastes*, the zinc-starch-vaseline paste, with corresponding medication, takes a high place. This paste is used with good result in combination with salicylic acid (acid. salicyl., 1–2; zinci oxidi et amyli, aa 25; vaselini, 50). The paste adheres to the face without any bandage; it is also dusted with starch. In the *Traumaticin* treatment, traumaticin (a solution of 1 part of gutta-percha in 10 to 15 parts of chloroform) is used as a medium for applying different remedies, such as chrysarobin, etc. It forms a pliant coating, and surpasses collodion by far in this respect.

Glycero-Gelatin is prepared in three forms: soft (5 per cent. gelatin added), hard (10 per cent. gelatin and water), and hard (10 per cent. gelatin without water). Before using, the preparation is liquefied by heat, and in this condition is spread on to the part affected, by means of a brush, and covered with mull.

In the preparation of ointment and plaster mulls, Unna's recommendation is followed to substitute lard by mutton fat, which renders unnecessary addition of paraffin or wax. The dressings are dipped into the melted mass, dried, and rolled up. The gutta-percha mull is considered to present many advantages.

A new kind of dermatological plaster has been introduced, the basis of which consists

of purified india-rubber and anhydrous lanolin worked up together to a remarkable adhesive mass. The mixture is medicated with various substances and spread upon linen, and it is then known as *Collemplastrum.* Among the advantages claimed for this kind of plaster are its low cost; that the mass does not separate from the linen; that, while possessing the adhesive properties of india-rubber plaster and lanolin, it favors the absorption of the added medicament; and that the plaster can be readily removed without leaving portions adherent to the skin. Besides the simple Collemplastrum adhæsivum, others are used, containing respectively 10 to 20 per cent. salicylic acid, 30 per cent. pyrogallic acid, 60 per cent. mercury and 5 per cent. carbolic acid, 50 per cent. thiol, 40 per cent. zinc oxide, 10 per cent. liquid pitch, etc., etc.—After *Pharm. Journ.*, May 23d.

MEDICINE.

THE RELATION OF CHOREA TO RHEUMATISM AND HEART DISEASE.

P. Meyer, in *Berliner Klin. Wochen*, gives an account of 121 cases of chorea treated in Hinoch's clinic during the past five years. In nine per cent. of the 121 cases there was a history of rheumatic symptoms, and in ten per cent. heart disease without any rheumatic symptoms was made out. In two per cent. of the cases both heart disease and rheumatism were present. From these statistics the author concludes that chorea is merely a symptom which can be induced by the most varied causes. This, however, is only a partial representation of this subject. Any hypothesis which does not take into consideration the functional predisposition to chorea cannot be accepted as adequate to explain its nature. This functional predisposition is necessarily always present. It essentially consists in the want of a due stability in certain motor areas. It is the element in chorea that is inherited, and without which the disease cannot be brought about. It is true that it is possible to have an acquired instability of certain cortical areas, as the result of many diverse injurious influences. Given this instability of the motor cortex, the causes that may induce choreic movements are very various. In one case it may be simple emotion, in another any internal or external poisonous agent. In the latter class may be included the poison of rheumatism. This poison then induces not only this disease, but the chorea and endocarditis. There are no grounds for entertaining the opinion sometimes expressed that chorea causes endocarditis. When the three diseases appear in the one case, it is more than probable that they are induced by some poison, either the rheumatic or allied poison, and in such cases the proper treatment is the treatment of the rheumatic state.—*Amn. Gyn. and Ped.*

VACCINATION AS A PREVENTIVE OF INFLUENZA.

Dr. Goldschmidt, of Madeira, hopes to conquer influenza by means of animal lymph, as re-vaccination against small-pox seems to confer almost perfect immunity from influenza. In consequence of the neglect of vaccination, small-pox prevails frequently in Madeira, and not long ago it carried off more than 1,000 victims. The doctor went in for re-vaccination, and now finds that not one patient out of 112 successful cases suffered from influenza, and out of 98 unsuccessfully vaccinated, only 15 persons were seized by the influenza, and these in each case but very slightly. Recently vaccinated infants did not catch the influenza. It therefore appears to follow that re-vaccination gives effective protection not only against small-pox, but also against influenza.—*British and Colonial Druggist.*

PHAGOCYTOSIS AND IMMUNITY.

The fact that one attack of a contagious malady, such as small-pox or scarlet fever, renders an individual immune against a second attack has never received adequate explanation. It is even more difficult to explain satisfactorily the immunity conferred on an animal by inoculating it with the attenuated virus of a disease which in its ordinary form is often, and in a few cases invariably, fatal, such, for instance, as protective inoculation for anthrax, chicken cholera, and the older method of vaccination to protect from or modify an attack of small-pox (*The British Medical Journal*). In a lecture recently delivered by Dr. Metchinikoff at the Pasteur Institute, an attempt is made to prove that the defending powers exercised by the amœboid cells of the organism are in a large measure concerned in conferring this immunity, The aggressive characters of these amœboid cells has earned for them the name of "phagocytes," and Metschnikoff points out that they are of difierent kinds, and originate in various ways. In connection with the subject of immunity, it is im-

portant to remember that these phagocytes can include and destroy micro-organisms; but the more malignant the micro-organisms the more rarely is it found within the phagocyte, and this is especially true of such diseases as chicken cholera, hog cholera given to pigeons and rabbits, and anthrax of mice. All these diseases have the character of general acute septicæmia and cause death within twenty or thirty-six hours. According to the views expressed in this lecture, we are to believe that when the micro-organisms are attacked by the phagocytes, an animal may recover from the disease. In the malignant forms, where the phagocytes do not intervene —that is, phagocytosis or amœbic warfare is not established—then the bacteria overrun the organism, and induce death. This partiality of the phagocytes is attributed to their sensitiveness to external influences, and especially to the chemical composition of their environment. These cells are powerfnlly attracted by many micro-organisms, and repelled by others. This attraction and repulsion are expressed by the terms "positive chemiotaxis" and "negative chemiotaxis." Now the basis of the theory appears to be that the chemiotaxis of the phagocytes of a given animal is mutable, and that cells may be gradually attracted to substances in a mild form from which they shrink when presented to them in a concentrated form. Hence by inoculating an animal with an attenuated virus the chemiotaxis, previously negative, will acquire positive characters, and at last be induced to attack the micro-organism of a malignant disease should occasion arise. Any attempt to explain immunity from infectious diseases on a rational basis will be very welcome. The theory propounded by Metschnikoff, is, like all the previous communications made by him on the subject of intracellular digestion, the outcome of patient and illustrious observation, and must command our attention. His views, formulated for the first time in a consecutive manner in this lecture, promise to revolutionize opinions as to inflammation and fever, and this attempt to explain the power of the cells to confer immunity from infectious diseases is sure to be hotly contested, for every important contribution to this confessedly obscure subject must necessarily be in a large measure hypothetical—*Med. Presse.*

THE DIAGNOSIS OF INCIPIENT MELANCHOLIA.

Dr. S. Grover Burnett, writes: Insomnia is present in some degree in all the forms of melancholia, being more marked in simple melancholia and melancholia agitata than it is in melancholia attonita, and melancholia with stupor; this would suggest again that the nuchalalgia was playing its part here in the role of production. I do not mean to assert that it is necessary at all times to have the nuchalalgia present in order that there may be insomnia, for I believe the delusions are often sufficient to keep patients awake. I have often, while making my rounds of the wards, at all hours of the night, had occasion to observe this condition, and it has not been uncommon to find these patients wide awake, with no indications of having been asleep.

Why are diagnostic symptoms important in incipient melancholia?

As I have said, it is in the early periods of the disease that it is so frequently improperly diagnosticated, and it is the inherent tendency of these very cases to become homicidal and suicidal. Such instances as these are the very ones that fill our daily newspapers with tragic sensationalism, and leave the general public wrapped in the mystic thought of some dastardly deed, which has simply been the outgrowth of a depressed and melancholy mind. Such an occurrence as this—which, I am sorry to say, is more common than you would imagine—is sufficient to point out to us the importance and usefulness of any symptom or group of symptoms that will lead to the recognition of a mental derangement which, sooner or later, will bring crime to the eyes of the public; humility, distress, and perhaps death in private life.

This propensity to take life may come upon them suddenly, or be gradual in its development. I recall the case of a large, heavy man, who was determined to take his life. In conversation he would reason quite well on many things, and when alone he would be seized with a fit of depression and a desire to kill himself. Notwithstanding he was closely watched, he evaded his attendant and threw himself head first down a stairway. He reasoned that the weight of his body, falling from a height on his head, would produce death. Unfortunately for him, he struck his head a glancing blow, as he jumped hurriedly and at an angle, rather than perpendicularly. He suffered from concussion of the brain, but survived his injury. All cutting and sharp-pointed instruments had to be taken from him. Shortly after being able to leave his bed he again evaded his nurse, and this time he jumped from the railing of a high piazza, head first, and, as he had reasoned, his weight was suf-

ficient to drive the cervical vertebræ into the base of the skull, producing instant death.

It is not uncommon to see melancholiacs whose real condition has not as yet been recognized awaiting some suggestion through which they may be able to carry out their morbid tendencies. A case of this kind was that of a gentleman who was noticed by his associates to be somewhat depressed. They thought to chide him a little and "drive away his blues," when he remarked he wished he was dead. One of the company carelessly remarked: "Go throw yourself over the stair railing." He deliberately carried out the suggestion before any of them had time to interfere. He fell through three floors on to a tile floor, killing himself, of course.

Suicidal and homicidal acts are frequent results of disappointed love affairs, and in these instances the real melancholia, which is undoubtedly secondary to the extreme disappointment and is responsible for the act, is often never recognized till it is too late.

Such occurrences are so common that it is useless to take up more time in illustrating this feature of melancholia, which is deserving of being considered an early diagnostic symptom, and is important both to the practitioner and to the neurologist. From a therapeutic and diagnostic standpoint it cannot be otherwse than recognized as of great efficacy. To arrive at a proper diagnosis. based upon various forms of depression, is not always an easy matter, for we find depression presenting itself in a variety of forms, each of which is dissimilar in its origin. Mental depression may be the initiative symptom of any form of mental disease, and, again, it may exist independent of any mental affection whatever. Gastric disorders often give rise to marked depression, also hysteria, hypochondria, and conditions of sadness. A differential diagnosis here is important, but not always easy to make. If the depression exists in connection with nuchalalgia and insomnia, the rest is easy.

Therapy, of course, should be based on the diagnosis made; hence, with a history which is in keeping with the presence of insomnia, the ache, and depression, we should feel quite positive as to what we have to deal with, and should institute precautions of safety and therapeutic measures at once. By this early interference I believe much mental aggravation and distress may be saved; but, in order to do this, it is essential for the physician to be conversant with the case and to have *entire* control, so that his instructions will be carried out in full.

As students about to enter into your new field of duties, I trust you may give this matter due consideration, for my clinical experience has taught me the value of these symptoms given you, and, since I have learned that they are ardently advocated as *clinical facts* by one so able as Dr. Gray, I am proud to have the privilege of presenting them to you for the first time.—*N. Y. Med. Jour.*

SURGERY.

WOUNDS OF THE INTRA-CRANIAL SINUSES.

Dr. W. T. Briggs in a paper upon this subject said that it is one which had not received from authors the attention its importance demanded, and that very little indeed had been written upon the subject. In many standard works upon surgery no reference whatever is made to it. He did not propose to shed additional light upon this neglected subject, but simply to give his impressions from the study of a number of cases of injuries of the sinuses which had fallen under his observation. The following is a summary of his paper.

The dural sinuses are so well protected by the tutamina cerebri that they are not often the subject of wounds. Occasionally an injury inflicted on the surface of the cranial walls without a lesion of the bones, or even of the scalp, may rupture a sinus and produce a fatal internal hæmorrhage.

A blow or fall may fracture the skull at one point and lacerate a sinus situated at a greater or less distance from the point of a fracture. More often a sinus is wounded by a sharp-pointed fragment of bone in comminuted depress fractures, or by the penetration of the skull by pointed or sharp-edged instruments, or by gun-shot wounds. Occasionally the sinuses are opened by the pointed teeth of the trephine.

The older writers upon surgery warned surgeons to avoid the situation of sinuses in the application of the trephine. Modern authors do not hesitate to advise the use of trephine directly over the sinuses if necessity demands. He had often removed sections of the skull an inch or more over sinuses with Galt's trephine, without injuring the vessels.

The result of such wounds depend on the character of the lesion. When a large opening is made in a sinus, the hæmorrhage, if not promptly restrained, may prove rapidly fatal. When the opening is direct and not large the hæmorrhage may be easily checked by appropriate means. When the blood does not escape through the external wound

but accumulates in the skull, compression of the brain ensues.

The entrance of air into sinuses, though they are calculated by their anatomical construction, is not of frequent occurrence.

The hæmorrhage arising from an open wound of a sinus may be easily controlled, and the opening permanently closed by prompt and appropriate treatment.

When the hæmorrhage is concealed and symptoms of compression arise in consequence, the trephine should be used for the removal of bone over the wounded sinus, that it may be properly treated.

The means that may be used in the treatment of wounded sinuses are, 1st, The encircling ligature; 2nd, The lateral ligature; 3rd, Suture; 4th, Acupressure; 5th, Forcipressure; 6th, Direct compression.

1st. The ligature might be used with success in arresting bleeding from sinuses, but the usually small opening in the skull and the consequent difficulty of placing it is an objection. Besides other means more easily used are equally effective.

2nd. The lateral ligature has proven effective in the hands of some surgeons but, in my opinion should not be restored to because its action is uncertain. It is very liable to slip and give rise to secondary hæmorrhage, besides it does not put the parts in the best condition for healing.

3rd. The edges of an opening in a wounded sinus may be closed and all bleeding stopped by saturing the edges of the wound with aseptic silk. When there is free space for work the suture is very effective, and may be practised with great confidence. In the application of the suture it is necessary that the intima should be brought in contact, which can be best accomplished by the continuous through and through stitch instead of the glover suture.

4th. The value of acupressure in controlling bleeding in these accidents is undoubted. The passage of a pin through the sides of the dural opening and the application of a thread thrown over the pin will effectually control the hæmorrhage. The compressing pin does not irritate and need not be retained very long.

5th. Forcipressure is also a valuable measure in the treatment of hæmorrhage from wounded sinuses. It is easy to grasp the mouth of a gaping sinus with hæmostatic forceps and leave it in situ until it produces permanent obliteration of the wound. It is complete and effective.

6th. The remedy to which I call attention last is by no means the least valuable means in our possession. Indeed, in my opinion, it is entirely sufficient to control any bleeding from wounded sinuses, and I have invariably depended on it in all the cases I have treated. I refer to direct compression. A small dossil of aseptic gauze or cotton is to be placed directly over the wound in the sinus, a small compress is then to be placed over the pledget, the flap of skin is then to be drawn over these, a compress over the flap so as to be retained by a well-adjusted bandage. The bandage and the external compress may be removed in a few days, but the internal compress is not to be disturbed until it is loosened by the discharges from the wound, or better still, until it can be washed away by a gentle stream of water. I do not think a better device can be utilized for the purpose. It is scarcely necessary to say that the treatment of wounds of the sinuses after hæmorrhage should be conducted upon strictly aseptic and antiseptic principles.

The author illustrated his paper by the report of a number of interesting cases which had occurred in his practice.—*Nashville Med. & Surg. Reporter.*

FOREIGN BODIES IN THE AIR PASSAGES.

Dr. Sprengel, of Dresden (*Centralblatt für Chirurgie*, April 4th), affirms that the question as to which of the bronchi is the seat of a foreign body impacted in the air passages can in many cases be readily and positively settled by the aid of auscultation. It is usually assumed that, if the air does not pass into one lung, the corresponding bronchus is completely closed by the foreign body, and that if the obstruction of the bronchus be incomplete, there will be a sibilant sound on inspiration at the seat of impaction, whilst the respiratory sounds on the opposite side will remain normal. Under certain circumstances, however, the determination of the precise situation of the foreign body may be attended with some difficulty. As a proof of this a case is recorded by Dr. Sprengel of a little girl who came under his care suffering from much dyspnœa in consequence of the presence of a foreign body in the air passage. There was a sibilant inspiratory sound over the right bronchus, while on the left side the respiratory sounds were almost inaudible. Tracheotomy was performed below the isthmus of the thyroid body, and the foreign body was seen occupying the whole lumen of the trachea, just above its bifurcation. The auscultatory signs in this case are to be explained, the author states,

by the nature of the foreign body, which was a large hollow bead, oval in form and open at each end. This, it is conjectured, was fixed at one end into the upper part of the right bronchus, and stretched across the lower end of the trachea, completely occluding by its distal portion the orifice of the bronchus on the left side. Thus the air was prevented from entering into the left lung, whilst it passed into the right lung through the tube formed by the large hollow bead, the narrowness of which, and perhaps an occasional occlusion by mucous, was the cause of the severe dyspnœa and of the sibilant sound during inspiration. This case, it is pointed out, shows that a hollow or tubular foreign body fixed at the lower part of the trachea may, by the signs which it produces, lead one to assume that it is fixed in one of the bronchi, since the air enters one lung and is excluded from the other. The absence of respiratory sounds on one side of the chest, or a sharp whistling sound heard over one bronchus, cannot be regarded as absolutely diagnostic of the presence of a foreign body in a bronchus unless we know that such body is a solid and not a tubular one.—*Brit. Med. Jour.*

GYNÆCOLOGY.

ON PERINEORRHAPHY BY DUKE'S OPERATION.

Dr. Thos. More Madden writes in the *Lancet:* The frequency of the occurrence of parturient lacerations of perineum, as well as the occasional gravity of their consequences, and the difficulties sometimes experienced in their reparation, may, I trust, be sufficient excuse for the following very brief communication on this subject. For many years I was in the habit of treating the injuries referred to by the older methods then in vogue. These procedures I have for some time, however, almost completely abandoned, having become familiar with the improved mode of treatment suggested for such cases by Mr. Duke, of Dublin, the advantages of which, I think, are such to ensure its general adoption in the treatment of the majority of instances of this kind. On first reading the author's account of his method of perineorrhaphy, it seemed to me as being probably a modification of Mr. Lawson Tait's ingenious operation for the same purpose; but on giving it a practical trial, however, I found that it was quite distinct. The differences in detail between the two operations which most impressed me were—(1) the absence of flaps, (2) the depth and shape of the incision, and (3) the introduction of the sutures from without in the operation recommended by Mr. Duke, whose procedure in the latter particular I have modified in my own practice by the adoption of a specially designed form of quill suture. The solidity of the union resulting from the healing of the deep incision is to my mind one of the great advantages of this operation, affording, as I have found, a means of reproducing the perineal body, which may be regarded as the keystone of the entire structure. The results of perineorrhaphy by Duke's method (with the technique of which I need not occupy space here, as it has been sufficiently described by the author) may be best exemplified by the results of the cases of perineal rupture, which within eighteen months were either sent up to me for operation or presented themselves at the out-patient department of the hospital, suffering from the usual consequences of this distressing accident. In only one of these cases did I fail to obtain primary union, and in that instance this was eventually secured by granulation; whilst in nine cases the operation resulted in complete restoration of the structural integrity of the injured parts. The average time occupied by the healing process was about ten days, and the patients then generally left the Hospital with a practically new perineal structure, the solidity of which was such that it would be difficult to imagine its disruption by any subsequent delivery however tedious or severe.—*Lancet.*

OBSTETRICS.

THE EXPRESSION OF THE PLACENTA,

By what is known as Credé's method, is sometimes followed by shock, supposed to be due to pressure upon an ovary or Fallopian tube. Three cases of this kind are reported in volume xiv of the "Transactions of the Edinburgh Obstetrical Society," and a correspondent of the *British Medical Journal* writes of another that occurred in his practice. In expressing the placenta, which seems to have been attended with difficulty, the operator felt something hard and round slip from between his thumb and the womb, the patient at the same time crying out in pain and becoming immediately unconscious. No great difficulty was experienced in bringing her to, but the accident is unpleasant and one that it should be easy to avoid. The patients to whom it has happened are all

spoken of as "nervous" subjects; but as it is well known that injury to the testicle produces shock altogether out of proportion to the apparent damage done, it is not surprising to find that pressure upon the ovary also causes great shock. Charpentier would no doubt find in this accident an argument in favor of his claim that traction upon the cord is preferable to abdominal pressure in the delivery of the placenta.—*N. W. Lancet.*

A SHORT REPORT OF THE USE OF ICHTHYOL IN DISEASES OF WOMEN.

Dr. Kotschau was led to use this drug in a case of painful pelvic peritonitis, with excellent results, after having observed that it acted well in relieving pain in cases of contusions or inflammations affecting joints, muscles, and bones. He then began to use it generally, and reports 127 cases, of which 28 were cases of endometritis cervicis; 16 were cases of endometritis corpus uteri; 52 perimetritis (pelveo-peritonitis, exudations, salpingitis, and oöphoritis); 4 pure metritis, the adnexa not being involved; 27 cases of parametritis.

The cases of cervical catarrh were treated by making applications of ichthyol to the portio vaginalis. In acute cases six to eight applications were made in all, each one at an interval of three to four days and in conjunction wlth warm injections and general massage. Of the 28 cases, 19 were cured, the other 9 showed no improvement.

Applied to the body of the uterus it has proven as effective as iodine or chloride of zinc, and never causes the colicky pains which these drugs produce at times.

In the 52 cases of perimetritis, with the exception of 6, a rapid cure was effected. A ten per cent. ichthyol-glycerin solution was applied on tampons, these applications being made twice a week by the writer and daily by the patients themselves, the patients also taking sitz baths daily. In the 6 cases no improvement took place.

Of the 27 cases of parametritis, 5 were not improved, except to slightly diminish the pains, 12 were completely cured, and the remaining 10 were markedly benefitted, though not entirely cured. In all of these cases ichthyol pills (0.1 t. d.) were given internally. The pills seemed to improve the patients' appetites and to hasten absorption of the exudation.

In the 4 cases of metritis no benefit was obtained by the use of the drug.

The author, therefore, recommends the use of ichthyol; for, even where it did not cure the disease, it frequently relieved the pains. —*Exchange.*

PÆDIATRICS.

HEADACHES OF CHILDHOOD.

Jules Simon (*Gaz. des hop.*, Nos. 36 and 37—*Revue des Malades de l'Enfance*, May, 1891) recognizes seven different groups of headaches:

1. The Headaches of Growth.—They are frontal, exaggerated by work, coincident with pains of the joints, periosteum and cardiac hypertrophy. Treatment, muscular rest, tonics, good food, phosphate of lime, beer and malt.

2. Headaches from Mental Strain.—The children are either very intelligent and excitable, working very hard; or, on the contrary, they are those of late mental development, who have difficulty in pursuing their studies. Treatment, in the first class of cases, cessation of mental work, physical exercise of all descriptions, without fatigue, and hydrotherapy. In the second class, a moderate amount of mental and physical exercise.

3. Headaches from Digestive Disturbances.—In children who eat too often, or too much, or too rapidly; appearing in from one to three hours after a meal. Treatment, strict regulation of diet; one of the bitter tonics before meals; warm drinks after meals; treat the constipation.

4. Nervous Headaches.—This form is easily recognized, it includes the headaches of those that are irritated by their surroundings, persons as well as circumstances, our future neurasthenics, epileptics or hysterics. Treatment: short douches, exercise, massage, valerian, aconite and antipyrin for the hysterical patients; belladonna and the bromides for the epileptics. Avoid colds.

5. Rheumatic or Gouty Headaches—Are sometimes accompanied by intense congestive phenomena simultating meningitis. They are recognized by their hereditary antecedents, by being associated with other pains; neuralgias, arthralgias, myalgias; the urine contains a great quantity of phosphates, oxalates and urates. Treatment, moderate feeding, exercise in the open air, Russian baths and rubbing; laxatives; alkalis; salicylate of soda in doses of from 0.25 to 0.30; tincture of colchicum, gtt. 10 to 15 daily.

6. Headaches of Anæmia and Intoxication.—In the first instance as the result

of lack of fresh air, bad hygiene; in the second, by malaria, carbon monoxide, excessive medication (iodine, opium, digitalis, belladonna). Treatment, remove the cause.

7. Headaches Produced by Lesions of the Nerves of Special Sense.—In the eyes, chronic conjunctivitis and keratitis, to be treated locally and with large doses of quinine; troubles of refraction like hypermetropia and astigmatism to be relieved by proper glasses. In the nose, polyps, hypertrophy of the turbinated bones to be treated locally. In the ear, adenoid vegetations, otitis, foreign bodies in the external auditory meatus.

HYGIENE.

ACCIDENTAL INOCULATIONS WITH TUBERCLE.

The presence of the tubercle bacillus affords a ready proof for the local development of a tubercular manifestation which has resulted from accidental inoculation. Jadassohn records two cases of lupus which had developed in this way. One patient was a butcher, upon whose finger tip an ulcer developed, and subsequently a typical lupus patch formed on the forearm, and another on the upper arm. The discovery of tubercle bacilli in the lesion proved it to be tubercular. In the second case, the lupus developed on the site of a tattoo, and coincided exactly with the lines of the tattooed design. The operator, it appeared, was phthisical, and had used his saliva in mixing the colors. —*Med. Press.*

THE NUTRITIVE VALUE OF RECTAL INJECTIONS OF EGG ALBUMEN.

The assertions of Voit and Bauer and Eichhorst to the effect that egg albumen is absorbed by the rectum only in the presence of a certain proportion of chloride of sodium, but is returned unaltered with the fæces if this reagent be absent, had led Huber to investigate this point anew, and to make his observations on man, and not on dogs, as his predecessors had done. The experiments were planned with great care, and the quantity of albumen removed from the body, both by the urine and the fæces, was estimated. As the outcome of several series of experiments, the results of which show a great agreement, the author gives as his conclusion that egg albumen simply beaten up is absorbed by the rectum, but only in very small quantities, and consequently a nutrient enema of this kind possesses hardly any value. When, however, a certain amount of common salt is added (15 grains to each egg in the present series of experiments,) the quantity of albumen absorbed is doubled. Peptonized egg albumen was absorbed in very slightly greater proportion than that treated with common salt, but of peptonized albumen with salt, between sixty and seventy per cent. was absorbed, and we, therefore, have in this mixture an extremely valuable material for nutrient enemata.

In no case of Huber's were the enemata expelled; nor was albuminuria ever found to occur after their use.

MEDICAL CHEMISTRY.

AN ALKALOID FRON TUBERCLE BACILLI.

By treating the contents of tubes containing agar-agar cultures of the tubercle bacillus with hot water acidulated with hydrochloric acid, filtering, evaporating, precipitating with platinum chloride, separating the double salt with hydrogen sulphide, filtering, and evaporating to dryness, Zuelzer (*Berliner klin. Wochenschrift*, 1891) was able to abtain a chloride of an alkaloid, 0.01 of which, injected into rabbits and guinea-pigs, caused, in from three to five minutes, increased frequency of respiration, elevation of temperature and protrusion of the eyeballs. The eyes were brilliant, the pupils slightly dilated and the conjunctiva injected. The protrusion was the more marked on the side on which the injection was made. The symptoms lasted for from fifteen to twenty minutes. Three rabbits died after injections of 0.02 or 0.03. The muscles into which the injections were made were reddened and the seat of hæmorrhages; there were also hæmorrhages in the mucous membrane of the stomach and of the upper portion of the duodenum. In two cases there was ascites. Similar results followed introduction of the substance into the conjunctival sac.—*Amer. Jour. Med. Science.*

NEWS AND MISCELLANY.

THE CROONIAN LECTURES.

Owing to the illness of Dr. Burdon Sanderson, who is now recovering from at attack of influenza, the Croonian Lectures have been postponed. Due notice will be given of the date fixed upon.

FEMALE PHARMACISTS IN FRANCE.

A bill is now before the French Legislature which provides for the admission of duly qualified females into pharmacy. This bill practically restores to women the rights they possessed five hundred years ago.

Clinical Lecture.

TUBERCULAR ADENITIS—ONYCHIA.

BY ERNEST LAPLACE, M. D.,

PROFESSOR OF PATHOLOGY AND CLINICAL SURGERY AT THE MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA—AND SUDGEON TO THE PHILADELPHIA HOSPITAL.

TUBERCULAR ADENITIS.

Gentlemen:—When we last met I brought before you a child with enlarged glands in the cervical region. At that time she was in poor condition to be operated upon, but having since had a tonic treatment, we find to-day that her temperature is lowered, her appearance is bright, and even the inflammatory condition of the glands has somewhat subsided, withal, we think we can now safely operate.

We will remove the tuberculous glands, pare the edges of the skin and approximate them so that the surface will scarcely bear a trace of the operation. Eventually the ulceration would heal up of itself, but would leave an ugly looking scar ; furthermore, instead of healing in a few days, it would run two or three months and drain the system to a much greater extent than we think wise to allow. Therefore, we will operate immediately.

The glands are tubercluous and have undergone fatty, or cheesy, degeneration. The ætiology and course of such affections having been made plain to the surgery of to-day, the indication to remove these glands is imperative. Here we have a tuberculous focus, in a part plentifully supplied with blood vessels. This blood traveling from the gland to other parts of the body, the lungs and brain, is bound more or less to infect the economy ; not necessarily to deposit the bacilli in these parts, and cause a tuberculosis or meningitis, but being laden with poisonous materials, it is not fitted to feed the other parts of the body, so that the sooner it is removed the better will it be for the child.

You will notice, towards the deeper portion of the gland, a grayish spot, which has undergone caseous degeneration. The surrounding structures have simply grown under the influence of the tubercle bacilli. They are still alive, but it may be that in a day or two they too will have died and undergone degeneration. Therefore, we will remove the whole mass.

We find that the sterno-cleido-mastoid muscle has formed adhesions with this mass ; has formed a sort of abscess wall, if you wish, from a chronic inflammation of its myolemma. Not daring any longer to use the knife, I now discard it, and, with the aid of my fingers, have exposed the internal jugular vein, pursuing the dissection further, I have come directly upon the carotid artery, the pulsations of which you can all see. Here the structures are so delicate that it is not wise to use even an ordinary curette.

Having removed all the infected glands, it is now our duty to get a surface wound that will not betray the fact that this child formerly had an ulcerative process here. The way to do this is simply to pare off the edges and approximate them carefully,, using two sets of sutures, a deep set to bear the strain caused by the tendency of the tissues to retract, and a superficial set to unite the surface and bring the edges into nice opposition.

Before closing the wound, we will inject into it a 10 per cent. solution of iodoform in ether. The ether evaporating, will leave a delicate covering of iodoform in every part of the wound.

As to a drainage tube it is not necessary in this case. The introduction of the drainage tube by Chassaignac was certainly one of the greatest steps in surgery since the time of the introduction of ligation of arteries, but you must remember *why* drainage was introduced. Its purpose was to remove foulness from the body, just as the filth is removed from our city by sewers. At that time, suppuration was looked upon

as necessary to the healing of a wound, and some means had to be provided for its removal, but to-day, knowing that we do not have suppuration if we are cleanly in our methods, it follows that we do not absolutely need the drainage tube. From the moment that we drain, we confess that we have fallen below our aim. Therefore, operating in an antiseptic way, we hope that whatever effusion takes place will be re-absorbed and will not accumulate, together with a mass of dead white blood corpuscles in the form of pus, thereby necessitating drainage.

Furthermore, in a wound like this, even if we were to use a thoroughly antiseptic drainage tube, acting as a foreign body it would of necessity irritate the parts promoting an effusion of serum, and it would be very hard for us to determine whether this effusion was natural or caused by irritation of the drainage tube. Of course if this wound were in a closed cavity, instead of in the neck, I would not run the risk of possible suppuration. Quite different would it be if we were operating in the peritoneal cavity. We would then have to put in a glass drainage tube, notwithstanding the irritation caused by it, as a small amount of pus might form and produce general peritonitis.

ONYCHIA.

The next case I wish to bring before you is one of onychia, an ingrowing toe nail. Onychia does not necessarily mean an ingrowing toe nail, but any inflammation of a nail. Apparently it is a slight affection to deal with. It is one which a physician will treat with mild methods for months, and the patient not get well. The idea of an operation for such a slight affection is revolting to the patient and even though the physician be firm in proposing an operation, if there is the slightest chance for the patient to get well in any other way, he will choose that way.

You know that a nail is simply a great amount of the same epithelium which is on the surface of the skin, all gathered into one spot, bound down by a cement substance which holds the cells together, bound together in a mass, so far away from the nourishing blood vessels that they become hardened, just as a corn becomes so hard that it begins to look like a nail. So also with the nail; it spreads from the mucous layer of malpighii about the matrix, exactly as the epithelium covering the rest of the skin spreads from that layer. But that particular layer in the matrix furnishes the epithelium born there with a chemical substance which is not found in epithelium elsewhere, a substance which gives these cells an adhesive property and binds them tightly one to the other, instead of letting them drop off one by one as they do from the skin in other parts of the body when they occupy such a remote seat from the blood vessels. That being the case, and the nail being hard, it may be considered a foreign body. If you take a piece of nail and insert it into a wound, it would act as an irritant, just as any foreign body would. So, imagine the irritation which takes place when you have a large nail, and a shoe which causes the edge of the nail to press into the skin. From the moment the skin has been destroyed by the pressure you have an ulceration and the nail pressing into wound is nothing more or less than a foreign body in the wound, and not until you remove the foreign body can you hope to cure the condition. The removal of the nail from the wound is the one object to be sought. There are several ways of reaching that end. There is a palliative way, which consists simply in depressing the skin around the nail and inserting a piece of cotton between the nail and the wound, thus removing the foreign body. In aggravated cases like this, however, not only is that measure painful, but the cotton gradually absorbs the secretions and itself becomes a foreign body, creating almost as much harm as the nail.

Again, here is a palliative treatment, which consists in putting on the toe some substance which will contract the tissues. Burnt alum is generally used for this purpose and its astringent action in contracting the blood vessels and tissues, removes the wound from the nail.

In some cases these palliative means may suffice, but in others operative treatment is necessary. There are several operations. One consists in removing the nail altogether, but this is not advisable, as it is only a small portion of the nail which does harm, and success may be gained without such disfigurement of the toe.

The best operation is that of Fehleisen, which is the removal of about one-third of the width of the nail in its whole length, including the matrix, together with the flesh beneath, removing it down to the bone. I have now done this, and place sutures, one above and one below, to draw together the edges of the wound I have made. The wound heals by first intention and in two

weeks you will not suspect that the patient had an ingrowing toe-nail.

MALIGNANT LYMPHOMA—CONSTIPATION—PERNICIOUS ANÆMIA—CHRONIC EXUDATIVE NEPHRITIS.

BY FRANCIS DELAFIELD, M. D.

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE, AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

MALIGNANT LYMPHOMA.

Gentlemen:—The first patient I present to you to-day, is a man 29 years of age, and a coachman by occupation. A year ago last January he noticed, for the first time, some pain at the inner aspect of the left arm and forearm, and extending to the tip of the little finger. This pain gradually began to manifest itself in all of the fingers of the left hand, together with loss of power of both the arm and forearm. In June 1890, that is about six months after the appearance of the first symptom, he noticed a swelling in the vicinity of the collar bone, and with this swelling came an exaggeration of the pain in the region of the shoulder joint. He came to this clinic at that time with a temperature of $100\frac{5}{10}$, and an examination of his blood and urine proved negative. He was put on the use of iodide of potassium, and has been taking as much of that drug as 90 grains three times a day, but with no appreciable benfit.

As you look at this man, you can readily notice an enlargement above the clavicle on the left side, and that this enlargement is made up of separate tumors as if they were lymphatic glands. These tumors can be also felt in the back of this man's neck. On making a physical examination of his chest I find on the right side an irregular loss of resonance immediately beneath the clavicle, and I get flatness on percussion. On the left side is a tumor projecting beneath the clavicle, as well as extending above it. I get flatness on percussion on this side, with some tenderness. The breathing on the right side can still be heard, but the breathing on the left side is altogether absent. Posteriorly, I get flatness over the upper part of both lungs, with absence of breathing over the left lung, though heard to some extent over the right.

From this view of the case, as it is presented to us, it is at once apparent that this man furnishes us an example of those tumors which originate in the lymphatic glands and which run a malignant course. These tumors continue throughout their entire course to have the same structure as that of the lymphatic glands themselves, though there may be some excess of cells, or some excess of connective tissue structure present, and although they may have this apparently, harmless structure, they still exhibit all the characteristic symptoms of malignant tumors. They not only increase in size, but the muscles, fascia, and the entire surrounding soft parts become infiltrated with the new growth, as do the true sarcomata and carcinomata. It is for this reason that these tumors are known by the name of malignant lymphomata, though they are sometimes called lympho-sarcoma and lympho-adenoma.

As a rule, these tumors behave very badly. The first symptom this man had was pain by reason of the pressure on the nerves going to the left arm. That pressure has continued till he has lost power completely in the arm, and this tumor will continue to grow until it will eventually press on the air passages and the blood vessels, in such a way as to destroy the life of the individual. He has so far escaped one of the most painful conditions of this growth and that is pressure on the descending vena-cava. When the growth in the thorax presses on the descending vena-cava, there is, as a result of this condition, a venous congestion of the head which is very distressing. This man suffers comparatively little pain yet, though he is running near to the end of his course.

These tumors are of such a malignant character that a good deal of attention has been directed towards their treatment. If they were within reach of the knife the indication would point to their removal, but inasmuch as they are intrathoracic, their removal is quite impracticable. A variety of medicinal agents have been adopted for the treatment of these growths, but they have all been generally speaking without any practical benefit. The only plan that has been of any use has been the employment of arsenic hypodermatically, and kept up to the point of tolerance. Keep the patient under its toxic influence for some days and allow him to come out of it, bringing him again under the influence of this drug. There have been cases of improvement reported by this plan of treatment, but so far

as this patient is concerned, I should not suppose any plan of treatment would afford him much relief.

CONSTIPATION.

Case 2. The next patient presents a well marked example of a rather numerous class of patients who have disturbances of sensation, without any organic lesion. This condition is more common in women than it is in men, though occasionally occurring in the latter.

The patient I now show you is a woman 45 years of age, who has suffered from an acute brochitis about a year and a half ago. And since that time has experienced a feeling of general malaise. She does not feel as strong as formerly and has lost some flesh and strength. She also complains of a feeling of pain referable to the right hypochondriac region and is troubled with constipation. She has no physical signs about the chest or abdomen, and is evidently suffering from no organic lesion.

You will find in practice, patients present themselves to you for treatment, who have disturbances of sensation, as this woman has, but with no organic or even functional disease. I have seen a great many cases of this character who date the beginning of their abnormal sensations from the attack of influenza, which has been epidemic here, and this particular affection seems to have brought out this disposition in patients in whom it has not been observed before. It does not follow that because these patients present no pathological lesion, they do not suffer. There is something the matter with them from their point of view, and it is always a question as to the particular way in which it is best to manage these patient while under your observation. It is always of great advantage in the treatment of these patients if you can find something wrong about them that you can regulate and correct. As you correct this condition, these patients gradually get better until finally the disturbance of sensation gradually passes away. In this woman the only thing that seems to be particularly wrong with her is her constipation, and with this constipation is a certain amount of flatulence. Her physician tells me that her bowels are easily moved by laxatives, so for that reason we will give her one of the least energetic of the laxative medicines and the one, at the same time, especially suited for her case. We will, therefore, recommend her to take every night on going to bed from eight to ten grains of asafœtida in capsules. This will help her to sleep, will act as a laxative, cure her disposition to flatulence, and, at the same time, exert a certain sedative eeffet on her general nervous system. In addition to this she should be warned against the use of tea or coffee, and should not be allowed to eat indigestible food, confining herself to the use of simple and nutritious elements of food. She should also be encouraged, despite her feeling of weakness and general malaise, to go out of doors and take moderate exercise daily in the open air. There is a still further advantage in the treatment of these cases in not paying more attention than you have to the particular disturbance of sensation of the patient. By managing this class of cases in this way you will find they will do very well indeed and you may in time rid them altogether of these disturbances of sensation which distressed them so much.

PERNICIOUS ANÆMIA.

The next patient I show you presents all the pathological symptoms typically characteristic of the form of disease from which she is suffering. She is a woman 46 years of age, and complains of irregular menstruation, headache, œdema of the feet and shortness of breath. Her temperature to-day is 100° F. and a week ago was 99$\frac{8}{10}$° F. She has a systolic murmur at the apex, and her urine has a specific gravity of 1,010, but contains no albumen. An examination of her blood shows diminution in red blood cells and hemoglobin.

This trouble began in this case about a year ago, as she states, but it is very likely it has lasted for a longer period and reached its development at this time. If you look at this woman you can readily notice that expression of languor and feebleness, as well as an extreme palor of the skin and mucous membrane. She is already far advanced in the disease, though there is no reason why she should not improve for a time. You can have no difficulty at arriving at a diagnosis of pernicious anæmia in this woman's case.

The treatment of this woman resolves itself into the use of proper food and medicine. Her diet should consist largely of milk, and she would do better in bed than going about. The medicines best suited for her case would be the use of iron and arsenic. Iron alone is not of as much service to this class of patients as it is in simple anæmia; nor does arsenic alone answer very well. The combination of iron and arsenic is the most efficient treatment, and of these they have to take considerable quantities. The best way to give iron is in the form of Blaud's pills, and

the best form of arsenic is the arsenious acid. I should commence treatment in this case with $\frac{1}{60}$ of a grain of arsenious acid and two Blaud's pills three times a day after meals. Then I would gradually run these up till she was able to take $\frac{1}{30}$ of a grain of arsenious acid and twelve Blaud's pills three times a day. As regards the iron there is no trouble experienced on the part of the patient in running it up, but in the use of the arsenic, of course, she will have to be watched, for the first evidence of arsenical poisoning, œdema of the eye-lids, pains in the stomach, vomiting, etc., and the moment you find you are giving too much arsenic, then diminish the dose to the point of tolerance. By these means it is possible for this woman to improve considerably for a time. The more you see of these cases of pernicious anæmia, the more you will recognize the fact that they are bad cases to treat. Some of them do not improve under treatment, while others that look bad when they apply for treatment, improve a good deal and they begin to think they are well. They lose their bad color, and their shortness of breath, their appetite again comes back and they are able to work and attend to their daily avocations as usual, but they have to take some iron for a very large part of the time to keep them from running down and relapsing into their former condition.

CHRONIC EXUDATIVE NEPHRITIS.

The next patient presents certain clinical characteristics somewhat similar to the woman you have just seen. She had, as you saw, an extreme palor of the countenance, and that palor, I told you, was characteristic of essential anæmia. This man's face is almost as pale, his lips, you will notice, are exceedingly anæmic, and yet although the palor in both cases is almost the same, you would expect to find in the case of this man some organic lesion to account for his trouble. This man's urine contains large quantities of albumen, his pulse is rapid and full, but without increased tension, the pulsation at the large arteries of the neck is considerably exaggerated, and his heart is increased in size, the apex being further to the left than it should be. He has also a double aortic murmur and his abdomen is somewhat distended.

We have then a man 37 years of age who tells us he was in ordinary health up to a period of about ten months ago. He took at that time, he states, medicine for the expulsion of a tapeworm, and has been sick ever since. Neither the medicine, nor the tapeworm, has had anything to do with his present condition. During these ten months he has been suffering from dyspnœa which keeps him from lying down comfortably at night, and he has to sleep propped up with pillows. He has not had much of a headache till lately, but he has a neuro-retinitis and some swelling of the feet and ankle joints. He does not notice any change in the quantity of urine passed, although he says that it is sometimes higher in color than at other times.

When you look at this man you notice the anæmia to which I have already referred, and though this anæmia shows itself very plainly in his face and mucous membrane, we would not find the same diminution in the hemiglobin and the number of red blood globules as in the case of the patient with essential anæmia. This patient, then, illustrates a straightforward case of one suffering from chronic endarteritis affecting the aortic valve and a nephritis, of an exudative type, which you can call either chronic or subacute, but which, judging from the specific gravity of the urine, has already affected the structure of the kidney to a very considerable extent. These are the two important lesions from which this man is suffering and he presents an exceedingly unfavorable example of a patient of this class. He is a man, judging from his present condition, whom you might expect to get worse and very rapidly too, and the way in which he seems likely to get worse rapidly is in the further development of dropsy, in the continuance of the anæmia, and the progressive loss of flesh and strength.

Now as to the best way of managing this patient. This man is a great deal too sick to be up and about. He ought, therefore, to be in bed or in a reclining chair at home. The trouble about keeping these men in bed is that they cannot lie down with comfort. His food for the present should be confined exclusively to the use of milk, and bye and bye we might add some solid food to this. Then when you try to get any further than this treatment with this class of patients, viz: rest and milk diet, you will find it difficult to get hold of anything that will benefit them to any great extent. His anæmic condition we may try to help by iron and inhalations of oxygen, and we may be able to get rid of the dropsy by the use of purgatives, by sweating and by diuretics. On the other hand, you may find none of these things will be of any use, and that the dropsy instead of improving, will get worse.

Then as regards the character of his cir-

culation. There is nothing there calling for interference, for though the heart is diseased, it is doing its work fairly well. The inflammation that is going on in the kidneys is an inflammation of some activity and one that we feel we ought to do something for, but yet it is a condition very difficult indeed to control. In such a case as this it is possible that sweating the patient may help the nephritis. Hot air baths may be of some service in this direction, though counter-iritation, hot applications, or cups over the lumbar region are not apparently of any use in in this class of cases.

As to the use of drugs in this condition we are very much in doubt. In some of these patients opium seems to be followed by improvement, while others with the same pathological condition are dangerously poisoned by small doses of this drug. I recently saw an old lady with nephritis in whom a single dose of an eighth of a grain of morphia came near destroying her life. Then of the other drugs which we use for this condition most frequently are the iodide of potassium and the bichloride of mercury. Sometimes, we use them separately, and sometimes in combination. As a rule we get better results from the use of these drugs in combination than otherwise. It is not necessary to use them in very large doses. One-thirty-second of a grain of the bichloride and from five to ten grains of the iodide of potassium three or four times a day will be sufficient.

When speaking thus discouragingly of this class of patients, I have in my mind those cases that when you first see them are just as bad physically as this man is. When you come across a case like this, with so bad clinical features as this man presents and with such a short history of getting steadily worse, you know very well that whatever you do in the way of treatment will not prove very satisfactory to you or your patient.

COMMUNICATIONS.

CONDITIONS FOLLOWING PARTURITION REQUIRING ABDOMINAL SECTION.[1]

BY E. E. MONTGOMERY.

PHILADELPHIA.

The developments of abdominal surgery, in the last twenty-five years have, in many directions, revolutionized the practice of both medicine and surgery. The field of surgery under its influence has been widely extended. Operative procedures that would have been thought homocidal, for diseased conditions, that were then believed to be beyond relief, are now daily practiced and recognized as correct and scientific methods of treatment. While medicine and surgery have been so ready to accept the aid afforded by the abdominal surgeon, but little, until very recently, has been done in the field of obstetrics. It is true that the earliest abdominal operation was probably for the relief of the woman who could not otherwise deliver herself, but beyond this, there had been but slight interference with the knife with ordinary processes. The similarity of inflammatory processes following parturition to those of ordinary surgical infectious diseases had been early recognized, but it has been only recently that the methods of procedure which would be considered as proper in surgery, have been instituted in obstetrics. Women have been permitted to die from puerperal peritonitis or puerperal metritis, with large collections of pus in the pelvis, abdomen, or walls of the uterus without the obstetrician apparently being able to appreciate the surgical maxim "Ubi pus, ibi evacua."

As a resident physician in the Phila. Hospital I remember a number of cases in which these septic cases following parturition were permitted to die and subsequent autopsy disclosed large pus collections,—collections which could have been readily washed out and the cavities drained without increasing the danger to the patients,—indeed the danger would have been very greatly lessened.

In late years the importance of decreasing the opportunity for the entrance and multiplication of septic germs has been very generally recognized. With this in view we find the freguent use of vaginal and intra-uterine antiseptic injections. While it is recognized that these injections are not desirable in non-septic cases, there are but few obstetricians of the present day who do not practice them where there is indication of sepsis. The necessarily infrequent use of injections, even in those cases receiving the best of care, the inability to bring the antiseptic material sufficiently in contact with the entire mucous surface to destroy the multiplying germs and render the surface sterile, have led to the institution of plans of procedure by which the decomposing material, affording origin and nutrition to

[1] Read before the Pennsylvania State Medical Society, June 4th, 1891.

these organisms, should be itself removed. To this end late writers upon obstetrics, almost without exception, highly recommend the use of the curette in every case of evident sepsis. By it the decomposing material is thoroughly removed, the cavity subsequently irrigated, and rendered practically sterile. This procedure has been effective in greatly reducing the mortality of such cases, but there are many cases in which the diseased conditions have extended beyond the uterine mucosa, before the obstetrician has had an opportunity to institute measures to limit its action. In such cases the disease may be in the form of peritonitis, metritis, salpingitis, or ovaritis.

In a case of septic trouble following parturition, when the uterine cavity has been curetted, and subsequently irrigated with reduction of the temperature or amelioration of the other unpleasant symptoms, or in cases where physical examination determines the presence of inflammatory exudation about the uterus, in the broad ligaments, or the uterine surfaces, shall we sit tamely by and devote ourselves simply to the administration of remedies which at best can have but a remote influence, and permit the life of a patient to be sacrificed? Such cases are just as amenable to treatment by proper surgical procedure as are those in which inflammatory pelvic trouble arises from other causes and at other periods. That this has been recognized, is evident from the increasing number of cases found in the literature of the day, where women have been subjected to abdominal operations following parturition,—cases attended with the most gratifying results.

It is my purpose to consider to-day, some of the conditions that may render abdominal operation not only justifiable but absolutely necessary, in order to save the life of the patient; and would promise by saying in any cases in which there is a development of septic symptoms following parturition, the obstetrician should be on the alert to discover the avenue through which the poison has entered the system and prepare to have measures instituted to bring about its arrest.

Small Ovarian Tumors.—The presence of small ovarian tumors, frequently of a dermoid character, occur sufficiently often in women who have given birth to children, to lead to the consideration of their possible presence and injury in the process of parturition, and are worthy of our attention. A number of cases have been reported of death from septic conditions following parturition where subsequent autopsy has disclosed that small growths of this character have been situated in the pelvis, have undergone rupture or bruising by the head of the child, and have consequently led to the subsequent fatal symptoms with the advent of the septic condition. Were such patients subjected to abdominal section, the diseased mass removed, the abdominal cavity irrigated and possibly drained, an entirely different termination would have been the result.

Tubal Disease.—The presence of pus collections in one or the other tube does not necessarily interfere with conception and subsequent pregnancy. The presence of such a collection, however, is a source of the greatest danger to the patient during the following parturition.

H. J. Boldt, in Proceedings of the Obstetrical Society, 1888, page 59, reports the case of a woman twenty-two years of age, who had been married five years, she had had three children, the last child born four weeks before she came under his observation. The labor was long, followed two hours subsequently by high temperature and profuse sweating, temperature varied from 102 to 105, with constant pain over the lower portion of the abdomen. The uterus was large and flabby; on either side a large, fluctuating, movable mass, which was supposed to be a distended fallopian tube. The case was diagnosed to be one of septic salpingitis and was strengthened by the facies of the patient. She died in collapse a few hours subsequent to abdominal section. In the operation there was great difficulty on account of adhesions. On the right side the tumor preved to be a distended fallopian tube, which ruptured during the separation of the adhesions, discharging its contents into the abdomen. On the left side the tumor was an encapsulated intra-peritoneal abscess, which also burst during the operation. The Fallopian tube was not abnormal, ovary very intimately connected by adhesions to the uterus, so that its removal would have been impossible without injury to the uterus itself. At the autopsy, an abscess was found in the substance of the muscular structure of the uterine wall, which contained about two drachms of pus. The cavity of the uterus measured about three and a half inches.

Large Fibroids.—The presence of large fibroid tumors in the walls of the uterus of a paturient woman is always a source of danger. In such cases the uterine sinuses about the tumors are quite large; the presence of the growth interferes with the proper contraction of the uterine muscular fibre, so that

the avenues for the entrance of septic material are rather increased. In my experience in the Philadelphia Hospital, I saw two cases of this character, in which the presence of a tumor was the cause of the development of septic trouble, leading to the termination of the lives of the patients. The development of sepsis in such cases should direct the mind of the obstetrician to the importance of at once removing the cause of the development of the trouble ; delay is attended with danger.

Retention of Placenta.—The incomplete removal from the uterus of the placenta, membranes, or clots, is a prolific source for the development of sepsis during the subsequent convalescence. It is needless to urge upon members of this society the importance of thoroughly emptying the uterus of fætal vestiges or envelopes, and the securing of firm contractions of the organ, with its cavity free from clots, but it is an unfortunate fact that neglect of these precautions frequently results in the development of sepsis. In any such case the first indication would be, of course, the thorough clearing out of the cavity of the uterus by means of the curette or finger —which is, perhaps, the best curette—and the subsequent irrigation of the uterine canal with a disinfectant solution. This method of treatment will, in many cases, be sufficient to bring the disease to a happy termination, but in cases where the presence of foreign material has not been recognized sufficiently early, we may find that the infection is no longer confined to the cavity of the uterus but has travelled into the tubes or through lymphatics or uterine sinuses, has involved the uterine walls and peri-uterine tissues. When a patient suffering from sepsis following parturition comes under observation, we should carefully examine to determine, if possible the existence of inflammatory trouble about the uterus, and where it is found, should not only resort to thorough emptying of the cavity of the uterus, but also to the removal of the inflammatory collection. The importance of this will be well illustrated by the history of the following patient: A woman about thirty-five years of age, who had had two or three children, and had gained quite a reputation by the successful performance of abortion upon herself, was seen in consultation with my friend Dr. Nock, March 6, of the present year. The woman had accomplished the discharge of the fœtus in a two and one-half months pregnancy, by the use of the handle of a tooth-brush, a week before. This was followed by chills, elevation of temperature, pain and tenderness over the abomen, and an offensive discharge. I was called with a view to advise as to the wisdom of dilating the uterus and removing the evidently decomposing placenta. Upon examination of the patient a mass of exudation and a sensation of fluctuation was felt posterior to the uterus, pushing the uterus well forward. I urged the importance of not only dilating the uterus and removing its contents, but of opening the abdomen and securing the thorough evacuation of the pus contents of the pelvis. The afternoon of the same day the patient was placed under the influence of an anæsthetic, the vagina thoroughly irrigated, the uterus dilated, and the offensive decomposing mass removed, the uterine cavity thoroughly irrigated with an acid sublimate solution, 1 to 2,000, and the abdomen then opened and a pint of pus evacuated from the pelvis. Both ovaries and tubes were removed, the abdomen thoroughly irrigated aud a drainage tube inserted. This patient recovered without an unpleasant symptom. Had either procedure been neglected, it would have resulted in the death of the patient.

In cases in which there is no apparent infiltration or extension of the disease to the surrounding structures, we may be content temporarily, with the curetting and disinfection of the cavity of the uterus, but should this treatment not be followed by subsidence of the symptoms of sepsis, thorough examination should be made, and even when failing to find evidence of intra-abdominal trouble, an exploratory incision should be made to make certain the presence or absence of such extension.

The writer has recently had an apportunity of saving a patient by this procedure, who would otherwise have died from septic accumulation which was not apparent by superficial examination.

The case of a young woman seen in consultation with my friend Dr. H. G. McCormick, of Williamsport, Pa. She had been confined Feb. 6th, in a very easy labor. On the 8th the temperature arose to 103, this subsequently subsided, but remained above normal, and on the 13th, it reached 106⅘, when I was called to see her. I examined the patient carefully, palpating the abdomen but found nothing within the peritoneal cavity to indicate a cause for the serious symptoms. The patient was placed under an anæsthetic and the finger introduced into the cavity of the uterus and this organ thoroughly dilated, when there arose at once an extremely disagreeable odor, this was found to be due to acute endometritis with decomposing decidua.

The cavity of the uterus was thoroughly curetted with the finger and with the instrument, subsequently irrigated and an iodoform gauze drain introduced up to the fundus. The drain was removed at the end of forty-eight hours. The temperature subsided in a few days to normal, at which it remained for some fifty-four hours, when it again began gradually to rise, remaining for some days at 100 to 101, once going up to 103. On the 8th of March, twenty-three days after the curretting her temperature again reached $106\frac{2}{5}$, and I was summoned to see her. I again palpated carefully the abdomen to determine whether there was any extension of inflammatory trouble from the uterus. I found no involvement of the tubes of broad ligaments, uterus freely movable, no fixation of either uterus, tubes or ovaries. I again dilated the cavity of the uterus with the finger and explored the entire cavity or internal surface of the uterus, to determine, if possible any collection of pus within its walls. There was an indication on the right side of there having been loss of tissue of the uterine cavity by the probable formation of an abscess, this was still further confirmed by the history of pus having been discharged from the uterus within the previous three weeks. A hard rubber drainage tube was inserted into the cavity of the uterus with the hope that it would promote drainage still further, and that the elevation of temperature would subside. The temperature was reduced under the influence of large doses of acetanlide, but there would be chilly stages occurring about every five or six hours, followed by an exaggerated temperature. On the morning of the 10th, I again returned in answer to a summons, determined to open the abdomen, with a view of ascertaining whether there was any obscure cause for the septic symptoms. The abdomen was opened, in this I was assisted by Drs. H. G. McCormick, Nutt, and Conley, of Williamsport, Pa., and Dr. T. B. Early of Philadelphia. The right ovary and tube were raised up, without finding any disease in the tube, the ovary was probably twice its normal size, apparently cystic. The left ovary and tube were then raised up, the tube showing in its abdominal end a small piece of lymph, the ovary upon its anterior surface showed also a piece of adherant lymph, the ovary was four times its normal size and was also apparently cystic. The condition did not offer what I thought sufficient cause for the serious condition of the patient. I then carefully went around the entire surface of the uterus to determine the presence of any pus collections within its walls, examined carefully the broad ligament but with a negative result. At a loss for something better to do, I ligated the pedicles, removed the ovaries and tubes, washed out the abdomen, closed the wound and replaced the patient in bed. The operation had been begun with the patient in a chill, and with a temperature of $104\frac{3}{5}$. The ovaries were examined, the right presenting nothing more than a serious collection without any well established cysts. Opening the left ovary, a teaspoonful of thick greenish, offensive pus was disclosed, and this we concluded to have been the cause of the profound symptoms, from which the patient had lately suffered. Her subsequent convalescence was normal, temperature subsiding and reaching normal within two days. She is now in excellent health, and is nursing her child. The milk supply having been lost for a time during the most profound symptoms.

Another case illustrating the importance and absolute necessity of abdominal section, was one seen in consultation with Dr. Hollopeter. The patient was a woman, 26 years of age, who had been confined the latter part of the last year, and owing to the fact that she was living in an adjoining room to her husband who was dying with phthisis, her physician was particularly careful in the exercise of antiseptic precautions, both during parturition and its subsequent convalescence. She did well until the end of the second week, when there was an elevation of temperature which continued at 102 to 105. She had profuse night sweats, became very greatly emaciated, suffered from continuous pain in the pelvis, a frequent desire to void her urine, and a steady decline in strength. Upon examination a mass of exudation was found apparently in front of the uterus, pressing upon the bladder, which gave the sensation of the presence of fluid. The operation was done, both ovaries were found to form abscess cavities the size of small oranges. The omentum was glued down to the tissues in front of the uterus, and it was with considerable difficulty that it could be separated, as it was folded up into a large inflammatory mass. It was ligated and this portion removed. The evening following the operation the patient had a temperature of 103, this lasted, however, but two hours, after which it subsided and did not subsequently reach 101. The patient rapidly increased in strength and appetite, with a discontinuance of sweating, and, at present, is in the enjoyment of excellent health.

To these cases I might add a number of

others illustrating the importance of abdominal section for diseased tubes and ovaries, which have given rise to profound septic symptoms following parturition. There are other cases in which the ovaries and tubes appear apparently healthy, but in which there has been an absorption of septic material from the uterine mucosa, giving rise to abscesses in the walls of the uterus.

During my term of service as a resident physician in the Philadelphia Hospital, I remember having seen a woman who had had an attack of puerperal metritis, from which she was apparently convalescing, her temperature, however, varied from 99 to 101, and her pulse continued rapid. She had been about, able to sit up part of the day, when she was suddenly taken with symptoms of collapse and died at the end of twenty-four hours. At the autopsy it was found that the fundus of the uterus had been the seat of an abscess or of multiple abscesses, from which it had entirely sloughed off, leaving the fundus open, giving the remainder of the uterus the appearance of a funnel.

In cases of abscesses in the uterine walls a late writer has advocated supra-vaginal hysterectomy; as the cervix forming the stump in such cases would be exceedingly short and difficult to bring up into angle of the wound, it has seemed to me that it would be a more preferable procedure to extirpate the uterus. This may be done through the vagina, or by Kraske's method, behind the anus, by enucleating the coccyx and resecting the sacrum, or by the abdominal method. Of the three different procedures, the vaginal or the Kraske method would be preferable.

In what I have said in advocacy of abdominal operations following parturition, I would not have it understood that I urge such procedures in every case of sepsis, on the contrary, I would urge first, that the patient should be subjected to a careful and thorough examination to determine the avenues by which the poison is entering the system, and ascertain measures to arrest its further progress.

Thus, in September of the past year, I saw in consultation with three other physicians, a case in which the question of abdominal incision had been considered and I was asked to decide as to its wisdom or necessity. The patient was very sensitive, had undergone an exceedingly difficult labor, and was at the time, suffering with a temperature of 103. I suggested that as it would be necessary to place the patient under the influence of an anesthetic to determine accurately the condition of the abdominal cavity, it would be better to make preparation for an abdominal operation should the examination disclose its necessity. The patient was etherized, when the examination disclosed that laceration had taken place through the peritoneum into the rectal septum, and a profuse offensive lochia was being discharged. Introducing the finger into the vagina it was found that the vaginal walls were lacerated laterally to the tuberosities of the ischia, and upon the left side the laceration had extended into the broad ligament, so that the finger could be projected against the peritoneum. With such an extensive laceration of the tissues, affording a large surface for the absorbtion of septic material, I at once concluded—in which conclusion my colleagues concurred—that there was here sufficient cause for the phenomena present, and the symptoms of abdominal complications were negative, consequently no incision was required. The sutures were removed from the perineum, the cavity of the vagina and uterus thoroughly washed out and the wound treated as an open one, by frequent irrigation. The temperature subsided, but two days following ran up to 106. She was at once placed upon a blanket and wrapped in a sheet wrung out of ice water, bathed in ice water, and acetanalide gr. x, given every hour until she had had three doses. Her temperature that evening was 100, the following day 99, and never rose above 100 during her subsequent convalescence.

In cases of sepsis, then, we would advise the following method of treatment.

1. Careful examination as to the avenues of entrance of septic material, and prompt measures to secure its elimination.

2. Where there is no vaginal or vulvar laceration to afford an entrance, the dilatations of the uterus and the thorough curetting of its cavity, followed by intra-uterine irrigation.

3. Where the presence of septic absorption has led to evident accumulation within the pelvis, or to the presence of fluctuating masses therein; prompt opening of the abdominal cavity, with the removal of the diseased organs, irrigation of the cavity and drainage.

4. Where no cause for septic disease is found in the pelvis, where curetting and irrigation of the uterus has had no influence upon the progress of the disease, an exploratory incision should be made to determine whether there are not small pus collections within the internal organs, serving as centers for the distribution of the poison. If the ovaries are somewhat enlarged without

giving rise to other symptoms to indicate the presence of pus within them, it should be determined if necessary, by puncture. In the healthy organ, puncture with an aseptic knife or needle will not injure it. If it contains pus as in our patient, such a plan would lead to its disclosure.

5. Where the uterine walls are the seat of abscesses, the uterus itself should be removed.

6. Where fibroid tumors within the walls of the uterus are associated with septic symptoms, operation should be done promptly and these growths with the fundus of the uterus removed.

7. If there has been any reason to suspect the presence of small dermoid or other ovarian cysts, and their injury during parturition, abdominal operation is urgently indicated, and where they have not been suspected and are the cause of the septic symptoms the course of procedure directed in this paper, would lead to their disclosure and removal.

CANCER OF THE PANCREAS.

BY J. L. MASTERS, M. D.,
PADDY'S RUN, OHIO.

I desire to report two cases of primary cancer of the pancreas, which it has been my privilege to see.

I was first called to see T. W. aged 43, May 7, 1888. He was tall, sparely built, and a farmer by occupation. He went on an occasional drinking spree. Nothing of interest in the family history.

He had had pneumonia, pleurisy and intermittent fever a number of years before. He had been kicked in the abdomen by a horse, but the injury had never given him any trouble.

When I first saw him he had what I thought to be remittent fever. He had elevated temperature and a rapid pulse following a chill, an acute headache, bilious vomiting, constipation, coated tongue and general malaise. The symptoms continued eight days under the influence of a calomel purge followed by quinine.

In ten days the symptoms returned followed by same treatment with cessation of symptoms in six days.

At the time of the second attack he told me he had been losing flesh rapidly, became easily tired, had palpitation of the heart, grew short of breath and had a great deal of pain in the top of his head.

I examined him very carefully at this time in a vain search for something upon which to base a diagnosis.

He remained under my care until Oct. 27, when he sought other advice. He passed into the hands of two different physicians before I again treated him, one doctor stating that he had consumption and the other attributing his trouble to the liver.

Feb. 2, 1889, I saw him again at which time he was complaining of pain over the spleen. His respirations were rapid, pulse, 110, temperature 101°. The abdomen was tympanitic and greatly distended. Bowels constipated; some frontal headache. The spleen was much enlarged, extending down to within two inches of the symphysis pubis and one inch to the right of the umbilicus. It was very firm and not tender. This enlargement had all taken place in four months, between Oct. 27th and Feb. 2nd, of the following year.

Another careful examination failed to discover any lesion except the enlarged spleen.

The skin was sallow or earthy. Jaundice was never present. The fever was intermittent at first but became remittent; the intermissions occurring in the morning. Sometime between Oct. and Feb. he commenced coughing, the cough being of an irritable kind with little or no expectoration.

Examination of the lungs negative. At times the skin was bathed in sweat.

The appetite continued good most of the time until the last two months, when he complained of getting tired of everything so soon. There was no dislike for any special article of food; but he vomited every time after taking cod liver oil which I tried to give him.

Nausea and vomiting were early symptoms, coming on usually with a coughing spell. He vomited only four times within the last six months.

One of the very disagreeable symptoms of which he complained was an intensely salty taste always present in the mouth.

Pyrosis, acid eructations and burning in the stomach were annoying symptoms. Bowels constipated and stools dark colored throughout the illness.

The urine was abundant, high colored and deposited a milky sediment. Examination never showed the presence of anything but the phosphates, but I have since wondered if there was not some fat present. The countenance was always anxious and pinched.

When in the upright position he had more pain and leaned forward to relax the abdominal muscles. The last few months

the tongue was clean. The pulse was weak and thready from 100 to 120. Temperature 100° to 103½°.

Pain was never a distressing symptom, often being entirely absent for days. When present it was always referred to the region of the spleen or liver. It was never lancinating but often dull and heavy. A tumor was never made out on account of the extreme abdominal distension and enlarged spleen.

Emaciation was progressive and he died April 15, 1890, a little more than eleven months after I first saw him. Death was due to exhaustion, the immediate cause being œdema of the lungs and hydrothorax, commencing about four days before death.

Diagnosis leucothythæmia. Treatment was symptomatic and supportive.

Autopsy 24 hours after death, Drs. Hoover, Hancock, Scott and Butterfield being present.

Rigor mortis well marked. Body greatly emaciated. Abdomen greatly distended. Heart very small and pale. Blood vessels stood out prominently on the surface (of heart). Pericardium full of fluid. Left lung completely adherent to chest wall and œdematous.

Right lung œdematous, partly adherent, non-adherent space filled with fluid. On the anterior surface of the middle lobe of the right lung was a small nodule, firm, reddish-brown, and the size of a cherry. In the abdominal cavity was about two pints of fluid. Intestines distended with gas, otherwise normal. The spleen was very much enlarged being about 10 in. by 8 in. by 5 in. It was very hard and a reddish blue in color.

The liver was slightly enlarged. A mass the shape of an egg was found on the anterior surface of the right lobe the size of a hulled walnut. The mucous coat of the stomach was injected. The duodenum and kidneys were normal.

The head of the pancreas was a nodular tumor with a rounded outline, composed of nodules varying in size from a pea to a small hickory nut. The tumor was about 2½ by 3 inches in diameter. The remainder of the pancreas was normal.

The lumbar glands were much enlarged, and some were nodular. They varied in size from ½ to 1½ inches in diameter. Microscopical examination was not obtained, because the specimen was permitted to spoil by the pathologist before an examination was made.

The opinion of all present was that the disease was primary cancer of the pancreas.

Case 2, occurred in Dr. Hoover's practice, of Ross, O., and to him I am indebted for notes on the case and the privilege of visiting the case and of attending and holding the autopsy.

Case 2. Mr. C. W. æt. 65, widower, occupation farmer. Among his children is an imbecile daughter and a son with tuberculous hip joint disease. His wife's death preceded his two or three years, she having died of cancer of the breast. Had never had any severe illness, nor had he ever received an injury.

The onset of his troubles was some digestive trouble in Jan. or Feb. 1890 with general malaise and loss of flesh. The loss of flesh was rapid and continuous, the whole amount lost being about 50 pounds.

There was more or less dull pain in the epigastrium, radiating to the thorax, the loin or the umbilical region. It was never severe enough to call for an anodyne except once or twice. The pain was not increased by motion or erect posture. He was free from pain the last month.

The qantity of urine was about normal, brownish yellow, staining the chamber an orange color. The sp. gr. 1028. It showed the presence of bile under the tinct. iodine test. It was not examined for fat.

The bowels were obstinately constipated. The stools were at first hard but later were soft. They were of an ashy color.

The skin was dry and very much jaundiced, being of a deep yellow. It (the jaundice) appeared five or six weeks before death and persisted.

The expression was not unnatural, the temperature about normal; pulse good and 76 to 90. He had pyrosis, acid eructations and burning in the stomach after meals.

The appetite was fair but capricious, there also being many things he could not eat.

He had occasional nausæ but never vomited. He had hiccough a few times.

Physical examination revealed a tumor in the epigastric region, firm and not painful to gentle pressure. On percussion it gave a dull note; on auscultation there was a distinct bruit. On palpation, pulsation was plainly felt, suggesting the possibility of the growth being an aneurism.

Through the kindness of Dr. H., I was permitted to see Mr. W. about Oct. 1, and was asked for a diagnosis. At a future date I gave it as my opinion that he had cancer of the pancreas. He died Oct. 27, after an illness of about 10 months.

An autopsy held 20 hours after death. The body was much emaciated, skin a deep yellow. A tumor plainly visible in the

epigastric region. Upon examining the abdominal contents it was found that the head of the pancreas was a somewhat flattened oval tumor 2½ in. diameter by 1½ in. thick of a yellowish red color. It was very firm and resisting. In the liver were numerous fatty patches. The borders of the liver were rounded but the size was about normal. The common duct was obstructed by compression, but I could easily pass a probe through it when the pressure was removed.

The duodenum was congested. There were neither adhesions nor peritonitis. The stomach was apparently healthy. Sections were examined microscopically and the pathologist pronounced the disease schirrus of the pancreas.

After looking over the clinical history of these two cases one could scarcely conclude they were the same disease had not an autopsy been held in each case and the pathological condition found to be the same. It is true the first case lacks the positive evidence of a microscopical examination, but microscopical examination placed it with the second case.

In the first place the spleen was enormously enlarged. This was due I think to the pressure from the tumor in the head of the pancreas upon the splenic vein, producing a long continued hyperæmia and consequent growth in the spleen. In case two the spleen was of natural size.

The first case was attended by fever. In case two there was none. The fever must have been due to either the local peritonitis about the tumor or was of a septic nature. Some of the nodules were breaking down in the center, and it is possible that the absorbents took up a certain amount of septic matter and produced septic fever.

In one case there was a cough, in the other none. The cough may have been produced by pressure on the cœliac plexus, initiating the pneumogastric and producing a reflex cough.

I cannot explain the abdominal distention unless it was due to fermentation from the want of the action of the pancreatic fluid upon the ailment.

These cases both occurred in males over forty years of age. They were both very difficult to diagnose, for among other reasons it was not thought the pancreas was apt to be the source of trouble. I am led to believe that pancreatic troubles are more common than we suspect. Within the last three years these two cases have come under my notice.

Out of 11,492 autopsies from all causes .011 were cancer of the pancreas. Of 622 internal cancers, more than .20 were of the pancreas. Of 460 cases of cancer in all parts of the body 6.3 per cent. were of the pancreas. Since cancer of the pancreas is of such frequent occurrence and presents such varied symptoms it behooves us to be on the lookout for it.

Among the symptoms usally found in cancer of the pancreas are to me digestive disturbance, pain of a neuralgic character in the epigastrium, jaundice appearing late in the disease but persistent; fat in the stools and urine, early and continued loss of flesh and strength, and the presence of a tumor in about one half the cases. It occurs much more frequently in males than females and usually after the age of forty.

Nausea and vomiting are usually present late in the disease; acid eructations, pyrosis, burning in the stomach, thirst, are the results of pressure on the pyloric end of the stomach. Hiccough is sometimes present.

Some of the diseases from which it must be differential are carcinoma of the stomach, diseases of the liver, aneurism of the aorta or cœliac axis, disease of the transverse colon, chronic pancreatis, and in my case, leukæmia.

By carefully excluding these diseases one can often arrive at a diagnosis when the positive symptoms of the disease are absent. In my case I was led to believe I had a case of leukæmia by the long continued fever, the very much enlarged spleen, the anæmia, the progresssive emaciation, by failing to find the tumor in the epigastric region and by the absence of pain of a severe type.

The treatment in these cases is only symptomatic and supportive for we have not yet found a medicine for the cure of cancer.

STRANGULATED HERNIA. WITH FECAL VOMITING 3½ DAYS—OPERATION—RECOVERY.

BY WM. K. SHEA, L. R. C. P.,

PHILADELPHIA.

Thursday evening, January 8, 1891, I was called to see Mrs. R. Her history was as follows: Age, 62 years; mother of a large family, delicate for a number of years, has a mitral regurgitant murmur, and suffered for the past 13 years with a femoral hernia, for which she never wore a truss, it would often come down, and as she described, form a large lump, but was easily reduced without the aid of a physician. On Sunday, 4th of January, without any extra effort being made by her, the rupture came down and could not be re-

duced. She sent for her physician (homœopath). On his arrival he made an examination, and tried to reduce it, but found it impossible to do so, he gave her some medicine and returned each day and made ineffectual efforts to reduce the hernia. Up to the day on which I was called her suffering was very great all the time, and she vomited incessantly. Her physician told her she should be operated on, but she would be obliged to go to a Hospital, to this she and her family strongly objected. As I was her son's family physician he suggested calling me in, first having discharged the homœopath. I found the woman in a very weak state, suffering intense pain, and a large tender tumor at right saphenous opening. After placing the woman on her back and flexing the legs on the abdomen I used ordinary taxis for about 5 or 10 minutes, and felt the tumor gradually give under my fingers, and then suddenly slip away, all pain ceased and the woman was quite comfortable. I left, naturally thinking I had been successful in reducing her hernia. Next day when I called she told me that she vomited all night and that the matter was very foul-smelling. I was shown the vomit and, of course, saw that it was of a fecal nature, and told her the only chance of life was to operate at once. She objected to operation, in fact would not listen to me. Next day, Saturday, the same objection, and on Sunday I asked for consultation, or said I should leave the case. They consented, and I called my friend, Dr. M. Price, who, of course, agreed with me, and we both used our best efforts to have her consent to operation, but all to no effect. Monday morning she still held out and not until the evening of Monday did she give her consent. I at once sent for Dr. Price and Dr. Hewish, and with their kind assistance began operation.

At 9 P. M. Monday, 12th January, I made an incision in the abdomen, median line, about two inches long, passed in my two fingers and found a small knuckle of intestine tightly bound down under the femoral arch. I was obliged to make an incission to relieve it, and not a moment too soon, as it was quite black and almost gangrenous. I brought the part up to the abdominal opening, washed it by pouring some warm water over it and returned all to the abdomen, sewed it up, put on a bandage and left the rest to nature. Half an hour after the operation the bowels were naturally moved, vomiting, of course, all ceased, and she made a splendid recovery. Only once after the operation was there any cause for alarm, on the third day the temperature went down to 95°, but with stimulants and warm jars it at once came up again. Stitches were removed nine days after operation, when the wound was nicely healed up, and now she is going around feeling better than she has felt for years. Here is a case vomiting fecal matter for over 3½ days, refusing all operative interference until the very last moment, and yet she makes a splendid recovery.

Society Reports.

MEDICAL SOCIETY OF NEW JERSEY.

125TH ANNUAL MEETING, HELD AT LONG BRANCH, JUNE 23 AND 24, 1891.

The meetings were presided over by Dr. James S. Green, of Elizabeth. Three sessions were held on Tuesday, the first day, and a final one on Wednesday. The first session was opened by prayer by Rev. C. J. Young, of Elberon. The society then listened to the reading of reports of committees and the transaction of certain business. Dr. H. Mitchell, Chairman of the Committee of Arrangements, read an address of welcome, and later in the day a representative from the Mayor and City Officials, and one from the Board of Trade, addressed the body and welcomed the members to the city.

The subject for general discussion at the next meeting, named by the Business Committee, is "The true pathology of sudden death in acute pneumonia, and the best means of averting it."

Dr. Andrew H. Smith, of New York, Dr. Charles Allen, Dr. John B. Roberts and some other gentlemen, were invited to seats in the body and to participate in the proceedings.

MEDICAL HISTORY OF THE STATE FOR THE YEAR.

Dr. D. C. English, chairman of the standing committee, read the report on the medical history of the State, during the year as it had been obtained from members in different counties.

The report opens with reference to the services and resignation of the former Chairman, Dr. T. J. Smith, of Bridgeton, and of the great importance of securing fuller and more reliable data on which to base a report that will be moderately satisfactory of the Committee and worthy the perusal and study of the profession, and a plan is suggested with that aim in view.

The report then gives an outline of the epidemic of "La Grippe," giving an account of its prevalence, type and fatality in the different Counties:

Atlantic Co.—Less in extent, but as severe in type as the year before, fatality light, mainly among the aged and infirm. Many cases in their onset resembling Typhoid fever. Cases prone to relapse.

Burlington Co.—General throughout County, but varying much in its manifestations. Severe frontal headache, less severe. Mental disturbance less frequent, physical prostration not so marked and recovery more rapid than last year.

Camden Co.—Very prevalent, many cases very severe; prostration extreme, in some cases following cephalgia or acute diarrhœa, others with no appreciable prodroma.

Cape May Co.—Epidemic prevalent and severe with rheumatism and neuralgia as sequelæ. Two fatal cases among aged reported.

Cumberland Co.—Prevalent in many localities, with pneumonia as a frequent complication or sequelæ.

Essex Co.—Generally prevalent, many severe cases, many who had been affected the year before were severely prostrated. In some sections from its manifestations it had been designated "pseudo-grippe," with symptoms not so precise and clinically definite, but enough of characteristic symptoms, signs and clinical aspects to show a cognate origin and course.

Gloucester Co.—No report.

Hudson Co.—Epidemic generally prevalent, worse in some localities than the year before.

Hunterdon Co.—Epidemic in severe form; very generally complicated with diseases of air passages especially pneumonia.

Mercer Co.—Prevalent, but mild in type.

Middlesex Co.—Ditto. Two cases reported complicated with diarrhœa and intestinal hæmorrhage, with slow convalescence.

Monmouth Co.—General throughout the County, milder in type than last year. Complications, bronchial or pulmonary nature instead of the nervous disorders of last year.

Morris Co.—Prevailed throughout County in varying degrees of extent, severity and fatality. More catarrhal complications and less general aching and soreness than last year. Another contrast was the frequency with which young children and infants were attacked.

Ocean Co.—Very prevalent with heart and lung complications. Fatality light.

Passaic Co.—Epidemic with greater severity in type than the year before. No deaths from it, but many from pneumonia which attacked persons who had been debilitated by it.

Salem and Somerset Counties.—No report.

Sussex Co.—Not extensive, but many cases in several localities with pneumonia and pleurisy as complications.

Union Co.—Very prevalent throughout the County, but varied much as to extent and severity of type. Pneumonia was a frequent complication, prostration was marked from the beginning of illness, nervous symptoms were prominent. Several cases with inflamed varicose veins as a sequelæ were reported.

Several cases were also reported with double pneumonia with a lack of the usual physical and rational signs of pulmonary disease.

Warren Co.—Prevalent, a few cases very severe and several deaths in complicated cases. Three waves of the epidemic were observed, one in February, another in April and the third in June.

DIPHTHERIA.

In Camden, Morris, Monmouth and Sussex Counties but few cases reported. In Camden City, several malignant cases are reported, which were fatal.

In Cape May and Union Counties it prevailed to a slight extent in some localities.

In Burlington Co.—But few cases are reported. Four fatal cases reported in a locality where night soil was freely used on the lands occupied by the families of those attacked.

In Cumberland Co.—But few cases except in Bridgeton, which reports 191 cases of mild type, with but few deaths.

Essex Co.—Several cases occurred in certain localities, but not prevalent or attended with much fatality. Newark reports 509 cases with 190 deaths, a decided decrease over the year before (1348 cases, with 366 deaths).

Middlesex Co.—Not prevalent. New Brunswick reports only 19 cases.

Passaic Co.—Not prevalent, except in Paterson, where it prevailed of a malignant type, and 35⅛ per cent. of deaths.

SCARLATINA.

Burlington Co.—Epidemics in different localities of mild type.

Cumberland, Hunterdon, Mercer and Union Counties.—But few cases, sporadic, several localities in each County, generally of mild type, sequelæ rare, and but few deaths.

Cape May Co.—Reports epidemics in two localities, and a few cases in others.

Essex Co.—Reports a decided decrease in number of cases.

Middlesex Co.—Many cases; but hardly epidemic anywhere, mild type and but few deaths.

Passaic Co.—It prevailed in parts of the County, in Paterson to a considerable extent where the mortality was 6¼ per cent.

RUBEOLA.

Burlington, Camden, Cumberland and Ocean Counties—Report a few cases in different localities, generally of mild type.

Cape May and Warren Counties.—Epidemics in certain localities, a few cases in other sections. One case: a child 11 years old with measles of severe type, which disappeared in three days, followed by Scarlatina of severe type which ran its course when Measles again appeared and the child died. In Phillipsburg it was malignant, in one section of city where the sanitary conditions were imperfect. Several deaths occurred from lung and cerebro-spinal disease complicating.

Atlantic, Hunterdon, Mercer, Morris, Passaic, Middlesex and Union Counties—Report epidemics, mostly of mild type, but in Southern part of Hunterdon Co. many of the cases were of a severe form.

An unusual tendency to affect adults and even very old people was observed in Middlesex Co.

Essex Co.—It has prevailed to a considerable extent, but generally of a mild type.

ROTHELN.

Atlantic and Camden Counties—Report many cases, but no general prevalence.

Burlington Co.—Reports epidemics, one noteworthy feature noticed, was enlargement of the superficial lymphatics of the head and neck, accompanied by much tenderness on pressure, but exhibiting no tendency to suppuration.

Mercer Co.—Reports epidemics. Many cases difficult to distinguish from Rubeola, but the two occurring at the same time it was noted that neither afforded protection from the other, nor did roseola offer immunity from scarlatina, which seemed to show that roseola is a distinct eruptive fever and not a hybrid.

Warren Co.—It prevailed extensively in some parts of County. Many children affected with Rubeolo had an attack of Rötheln within a month of the time of their recovery from measles.

PERTUSSIS.

Camden and Hunterdon Counties—Reports a few cases, but no general prevalence.

Cumberland, Mercer, Middlesex and Monmouth Counties—Report epidemics in various localities.

MALARIAL FEVERS.

Only three Reporters make references thereto.

Essex and Hunterdon Counties—Report less prevalence of milder form and more amenable to treatment than for many years.

Middlesex Co.—Reports malaria prevalent in sections where it is usually found.

TYPHOID FEVERS.

Burlington, Camden, Cumberland, Mercer, Middlesex and Union Counties—Report but few cases, mostly of a mild type.

Burlington—51 cases reported, with 4 deaths.

Essex Co.—Newark City reports 359 cases, with 115 deaths, as against 508 cases, with 172 deaths last year.

Warren Co.—A few cases of mild type.

Hunterdon Co.—A few cases in some localities of a low and dangerous form with maximum death rate.

BOWEL DISEASES AMONG CHILDREN.

Atlantic Co.—In the interior many cases of Enteric disease in children.

Cumberland Co.—Cholera Infantum rarely seen.

Middlesex Co.—That Cholera Infantum has been much less than in former years, attributed in New Brunswick to thorough and constant disinfection (with Bromine) of the streets and foul places.

Union Co.—Usual amount, but very mild in type, yielding to simple remedies. Very few fatal cases.

RHEUMATISM.

Prevailed to an unusual extent during the Winter and Early Spring throughout *Atlantic, Cape May and Middlesex Counties;* it was of average frequency in *Hunterdon Co.*, with more complication than usual. It was one of the principal complications and sequelæ of La Grippe.

PNEUMONIA.

Camden Co.—Reports a large number of cases, but not many fatal.

Cumberland Co.—In one locality more extensive than for many years.

Essex Co.—Prevailed to a limited extent, but not of dangerous type.

Hunterdon Co.—Prevalent, and of severe form throughout the County, some fatal in early stages.

Middlesex Co.—A larger number of cases than usual, and several deaths.

Passaic Co.—In Paterson 109 deaths from it during April and May. Last year, same months, 17. The high death rate is attributed to the extreme debility and premature exposure following the grippe.

Warren Co.—In Belvidere it was prevalent. Some of the other Counties report a few cases.

OTHER DISEASES NOTED.

Laryngitis as prevalent in *Camden and Union Counties.*

Follicular Tonsillitis very prevalent in *Cape May Co.*

Conjunctivitis with a tendency to corneal ulceration, a large number of cases in some localities in *Middlesex Co.*

Dysentery as epidemic in Hamburg, *Sussex Co.*, 50 cases with 10 deaths; also in some parts of *Middlesex Co.*

Apoplexy frequent among the aged in *Hunterdon Co.*

Tuberculosis, a slight increase in *Essex Co.* and a decided decrease in *Warren Co.*

Atlantic, Passaic and Hunterdon Counties only report an unusual amount of sickness.

Basing our conclusions on the reports received and on correspondence with the Reporters in relation thereto, Intermittent, Remittent and Typhoid Fevers, Cholera Infantum and Diphtheria, have been far less prevalent in the State during the year than usual; while Pneumonia and Catarrhal affections generally, Rheumatism and Rubeola have shown a decided increase. Scarlatina has not exceeded the average of the past few years.

The Zymotic diseases were generally of a mild type, and their fatality very light. Of the epidemic "La Grippe," we believe it has been considerably less in extent, and as a rule, less severe in type than the year before, while the percentage of mortality has probably been increased by the prevalence of pneumonia as one of its principal complications.

The improvement of the Sanitary condition of the towns and cities by construction of sewers, and introduction of a pure water supply is referred to as a hopeful sign for the future healthfulness of the State.

Reference is then made to some observations on therapeutic treatment of disease.

Large doses of calomel in the beginning of treatment in Diphtheria.

Infusion of Digitalis in Scarlatina.

Veratrum viridi in full doses to abort suppuration in acute Tonsillitis; also in the first stage of pneumonia to lessen its severity and mortality.

Hypodermic injections of strychnia and nitro-glycerin in cardiac weakness in pneumonia, and especially when cardiac failure is feared in the course of pneumonia or of pleurisy.

Salol, in catarrhal and croupous pneumonia; also in Typhoid Fever to reduce temperature, modify the course of the disease, and assist digestion and assimilation; also in cases of partial retention of urine that accompanies enlarged prostate or the more common venous urethral stenosis of old men.

Peroxide of Hydrogen as a germicide in purulent surfaces and sinuses containing or discharging pus; also internally in gastralgia accompanying indigestion with flatulent eructations.

A case of Hepatic Tumor is then referred to.

Also a case resembling in many respects, one of Arsenical poisoning; persistent vomiting and purging for 24 to 36 hours; intense spasmodic pains in stomach, bowels, throat, back and extremities, loss of voice, weakness, prostration and feeble pulse; suppression of urine for 72 hours, brain continuously clear. It was a case of "La Grippe," which recovered.

The rapid strides and new successes in the field of Surgery is referred to, and the remarks of one of the Reporters in reference to Koch's discovery and the distribution and sale of his fluid or lymph.

Also the use of Anæsthetics in Midwifery, and the use of the forceps for facilitating labor.

Attention is called to the 71 diplomas and certificates filed with the County Clerk of Essex Co. during the year.

To the enlargement of the Paterson General Hospital.

To the 11 deaths of members of the Medical Society of New Jersey during the year:

Dr. Henry H. Longstreet, of Bordentown.

Dr. Denman Bevis Ingersoll, of May's Landing.

Dr. Theodore Crane, of Hackettstown.

Dr. Joseph Parrish, of Burlington.

Dr. W. H. O. Taylor, of Union Hill.

Dr. Smith H. Lewis, of Pennington.

Dr. Rodolph E. Gerlach, of Trenton.

Dr. Henry A. Kennedy, of Cape May City.

Dr. Sylvester H. Hunt, of Long Branch.

Dr. J. O. Pumeo, of Elizabeth.
Dr. Abraham Coles, of Newark.

The Report closes with an appropriate allusion to the death of the last elected Honorary Member of the State Society, Dr. Joseph Leidy, of Philadelphia, Pa.

NOMINATIONS FOR HONORARY MEMBERSHIP.

The following nominations for honorary membership were made: Drs. F. R. S. Dennis, V. P. Gibney and John H. Ripley, of New York. Referred to the Committee on Nominations.

PERMANENT DELEGATES.

The last two or three annual meetings the question had been discussed as to establishing a permanent membership. Dr. H. Mitchell, chairman of the committee "On Permanent Membership," appointed at the last annual meeting, read the report of the committee, which favored the election of permanent delegates by the different district societies, said delegates to forfeit their membership should they absent themselves from two successive annual meetings of the state society. The report and resolution were adopted.

A PLETHORIC TREASURY.

Dr. Charles Kipp, of Newark, acted in the absence of the treasurer. It appeared there was considerable surplus in the treasury, and consequently a motion to reduce the annual assessment to one dollar for the ensuing year prevailed without opposition.

THE PRESIDENT'S ANNUAL ADDRESS.

Dr. James S. Green, president of the Society, chose for the title of his address, "A View of Modern Surgery from the Standpoint of a General Practitioner." The era of modern surgery, he said, commenced with the discovery and practical use of anæsthetics. In October, 1846, Dr. Morton of Boston, demonstrated that sulphuric ether could be used in capital operations with the entire prevention of pain. In 1847, Simpson, of Edinburg, introduced chloroform, but owing to the greater danger of this agent, ether was still commonly used in this country. Speaking of cocaine and local anæsthesia, he said the possibilities of cocaine had not yet been fully appreciated by the profession at large.

PROPER CARE AND DRESSING OF WOUNDS.

More or less varied ideas had prevailed regarding the proper care and dressing of wounds previous to the modern era of surgery, but the advantages of present methods over the former might be inferred from the statement that formerly surgeons sought to produce suppuration and prevent primary union, while now they aim to prevent suppuration and obtain union by first intention. One superiority of modern surgery was related to our ability to conquer hæmorrhage during operations by means of the Esmarch bandage. Modern surgery had given special attention to the region of the abdomen, and lately a great deal of study had been given appendicitis, a condition which was now known to be of frequent occurrence, and responsible for a large number of deaths. It had been shown that early laparotomy in recurring appendicitis was not only justifiable, but was demanded.

The reader also referred to the revival of the operation of suprapubic cystotomy, the application of aseptic and antiseptic surgery in the treatment of phlegmon, to tenotomy for deformities, and emphasized the need of more general application of the principles of modern surgery to the treatment of burns. The custom still prevailed unduly of wrapping the burn in cotton and oil, and exposing it to dirt, as well as of favoring sepsis by leaving dead tissue to slough instead of scraping it away. Brain surgery, and the moral obligations of surgeons, also received attention.

Mr. Morris, representing the Long Branch Commissioners, and Mr. McFadden, of the Board of Trade, were introduced, and in well chosen words welcomed the society to Long Branch, and invited the members to visit the different points of interest.

INTUBATION OF THE LARYNX.

Dr. Walter B. Johnson, of Paterson, read an exhaustive paper on the subject of intubation of the larynx in diphtheria, including a report of eighteen cases. To be successful, intubation depended upon: 1, The use of a properly constructed instrument; 2, The skill and judgment of the operator; 3, The delicacy of the operation; 4, Knowledge of the requisite medical treatment; 5, Proper feeding and care; 6, The variety of the disease; 7, The severity of the epidemic; 8, The extent of the complications; 9, Careful examination of the patient at frequent intervals and preparation for combatting complications or obstructions to the tube.

Regarding the construction of the tube, the author quoted from Dr. Dillon Brown's paper which contained an account of the steps in the perfection of the tube as it had been invented by Dr. O'Dwyer. Instruments were exhibited. Of the eighteen cases

reported in the paper, only three recovered. In all the operation was performed during the night of the fatal epidemic of diphtheria in Paterson between July 1890, and February, 1891. In seven months during this epidemic 259 cases of diptheria were reported, with 103 deaths. The eighteen cases undoubtedly would have shown a more favorable result had the epidemic not been of so severe a form. The tube was a source of relief and comfort in nearly every case. Even if the mortality had not been lessened, the relief from dyspnœa and the comfort afforded would justify the operation.

Delegates from other states were present, as follows: Dr. Crothers, of Connecticut, Dr. Swing, of Pennsylvania, Drs. Furbeck and Willy Meyer, of New York; also two members from the Pharmaceutical Association, New Jersey.

DISCUSSION ON TUBERCULOSIS.

The discussion upon the subject presented at the last annual meeting, "Tuberculosis—the Potential Factors in its Spread, Whether Hereditary Capacity, Inherited Bacillus, or Transmission from Inferior Animals," was opened with a paper by Dr. Edgar Holden, of Newark. Comparatively few doubted at present the ætiological relation between tuberculosis and the tubercle bacillus of Koch. The two prime factors in discussing the subject under consideration were, the bacillus, and man's vulnerability. The tubercle bacillus could be shown to be propagated by inhalation, by inoculation, by ingestion, and by inheritance, although the proof of some of these modes of propagation were not altogether convincing. The author reviewed the nature of this proof, and gave considerable credit to Philadelphia, Boston, and Baltimore. The chief method of acquiring tuberculosis was through inhalation of dried particles in the air containing the bacillus tuberculosis. The much greater danger from this source was clearly shown to exist in rooms where those suffering from tuberculosis lived, and especially where no attention was given the proper disposal of the sputa. The possibility of spreading the disease by inoculation was worthy of thought by butchers and by physicians in making autopsies and performing operations. As to propagation by ingestion of food, it might be stated that Shurely and Gibbs, of Detroit, denied that the tubercle bacillus of animals and that of man were identical. But the author thought there was satisfactory evidence of the danger of tuberculosis in the meat of all animals, however limited might be the disease. Nor was it necessary that the udder itself be diseased to make the milk of a tubercular cow unsafe. In this country three to twelve out of every hundred cows were said to have tuberculosis. The need of legislative action was manifest.

Regarding the question of transmission of tuberculosis by inheritance, there had been much dispute. The author did not doubt the inheritance of a vulnerability or tendency to the disease, but could only review the literature regarding the possibility of the tubercle bacillus being transmitted from the mother to the offspring. Positive evidence on this subject was hardly to be found, although a few authors had claimed to have found the bacillus in the fœtus before birth.

Elsewhere Dr. Holden had shown by statistics of life insurance that few persons lived to seventy-five years among whose near relatives there had been consumption, while it was not at all difficult from the same statistics to find over one hundred persons over seventy-five years of age among whose relatives there was no history of consumption. In concluding his paper the author expressed his conviction that the spread of tuberculosis was in proportion to exposure to the bacillus and the vulnerability of the individual.

Dr. J. W. Stickler, of Orange, held essentially the views expressed by the author, in proof of which views he analysed some statistics given by the late Prof. Austin Flint, and reviewed some facts stated in literature. Some cases had been reported of tuberculosis in the fœtus, or in the infant dying soon after birth; but the reporter had not stated that he had found the bacillus. The author thought that if the bacillus itself was inherited it must be limited to cases of tuberculosis of the testes, of the ovaries, of the placenta, or general infection.

DIET AND CARE OF NEW JERSEY COWS.

Dr. Henry L. Coit, of Newark, chairman of the committee "To investigate the subject of the influence of diet and care of cows upon the constitution of their milk, and the action of this milk upon the human subject when it proves injurious: Further, to determine what current practices in their feeding and care are prejudicial to this probuct." Read the report, which was only a provisional one. The committee was to consist of forty members, different counties to be represented, and Dr. Coit had found the work of organizing the committee and carrying on the investigation a slow one because a great one. The paper pointed out some reasons for making this investigation, all based on the import-

ance of obtaining pure milk for food, especially as food for infants. That the diet had a marked influence on the constitution of the milk had often been shown, and he had no hesitation in saying that a large proportion of the dairymen of his own state used unhealthful products, such as were obtained from breweries, &c. In his opinion there ought to be a constant relation between the price of milk and its quality. The dairy people got only two cents a quart for their milk while the average cost of good milk had been shown to be one and eight-tenths cent. The temptation to use unhealthful food products was evident.

The committee's request to be continued was granted.

SOME RECENT VIEWS ON PERITONITIS.

Dr. John G. Ryerson, third vice-president, read a paper with this title. The interest in the appendix, he said, was so widespread at the present time, and disease here so frequent, that the consideration of peritonitis in general would excite little interest. He would, therefore, speak only of a few points in the history of peritonitis of which the appendix might be the cause.

McBurney and other surgeons of to-day advocated early surgical interference in appendicitis and removal of the appendix. They taught that the surgeon should be called in early by the attending physician; that, if possible, he should make frequent visits before operating in order to become familiar with the case by personal observation. Now, we know that septic peritonitis begins early; that from the beginning the conditions necessary for its septic character occur, and that when once this form of peritonitis sets in even surgical interference will not save the patient. In this form of the disease, therefore, there lay little hope of diminishing the mortality rate. But under the older method of treatment, according to Noyes, the percentage of deaths was only fifteen, and even those who favored modern surgical treatment admitted that one-half, or at least two-fifths, of this percentage could be placed to the credit of septic peritonitis. Reasoning in this way, and taking the figures of those who favored surgical interference, the author arrived at the conclusion that modern surgery had left only five per cent. of all cases on which to improve of existing modes of treatment. While, therefore, the surgeon to-day was most active and zealous, he thought the physician should not give up the field. There were two methods of medical treatment in vogue, the opium and the saline. For his own part, he favored the old fashioned method introduced by Alonzo Clark, of quieting pain and stopping peristaltic action by the administration of a sufficient amount of opium to accomplish this purpose. He believed the general adoption of this method would be more likely to reduce the mortality rate than more frequent resort to surgical interference.

In the ætiology of appendicitis, the possibility of its being of epidemic character had scarcely received mention, yet its history pointed pretty strongly in that direction. This suggested the possibility of the blood being at fault, or a microbe being the cause, and of grounds for using drugs which had not yet been appreciated.

AN ATTEMPT TO SHOW WHAT NEW JERSEY SURGEONS HAVE DONE IN ABDOMINAL SURGERY.

Dr. Edward J. Ill, gave statistics in this paper based on more or less limited reports of operations in abdominal surgery sent him by different physicians and surgeons of the state, including a brief account of nearly one hundred cases in his own practice. It seemed that, in spite of the fact that New Jersey lay between two great surgical centers, Philadelphia and New York, a large number of operations in abdominal surgery had been performed by her own medical profession.

OFFICERS FOR THE ENSUING YEAR.

For President, Dr. E. J. Marsh, of Paterson; First Vice-President, Dr. George T. Welch, of Passaic; Second Vice-President, Dr. John G. Ryerson, of Boonton; Third Vice-President, Dr. Sproull; Corresponding Secretary, Dr. William Elmer, Jr.; Recording Secretary, Dr. William Pierson; Treasurer, Dr. Archibald Mercer. Place of meeting, Atlantic City.

SELECTED FORMULÆ.

THE EMPLOYMENT OF KOLA NUT.

Huchard gives the following prescription in the *Revue Général de Clinique et de Thérapeutique* for the administration of kola nut:

℞

Tincture of kola	1	ounce.
Tincture of coca	1	ounce.
Tincture of squills	½	ounce.
Tincture of digitalis	2	drachms.
Simple syrup	2½	ounces.
Red wine	1	pint.—M.

Allow the sediment to settle, and then decant and filter. Two or three teaspoonfuls

of this mixture may be given each day for eight or ten days in cases of cardiac disease requiring tonics. In other cases the following may be employed:

℞ Fluid extract of kola } of each 6 drachms. M.
Fluid extract of coca }

A small teaspoonful should be taken after luncheon, with a little simple syrup or Malaga wine. This mixture should not be given at night, because the kola produces insomnia in some patients. The dose of it should be from 20 to 30 drops three times a day: as, for example, at 8 o'clock in the morning, at midday, and at 4 o'clock in the afternoon.—*Med. News.*

PRURITIS ANI.

Kelsey prescribes acetate of potassium, ten grains three times a day internally, and a ten per cent. solution of nitrate of silver locally, to be followed by the following ointment:

℞ Menthol.....1 drachm.
Simple cerate.....2 ounces.
Oil sweet almonds.....1 ounce.
Carbolic acid.....1 drachm.
Powdered oxida of zinc.....2 drachms.
M. Sig. Apply morning, noon, and night, after cleansing the parts.

TREATMENT OF TYPHOID FEVER.

The *Revue Général de Clinqiue et de Thérapeutique* gives the following method used by Tessier in the treatment of typhoid fever: Morning and night a powder composed of 5 grains of alpha-napthol and 3 grains of salicylate of bismuth is given. In addition four injections are used, at intervals of twenty-four hours, with the object of increasing diuresis. After the midday injection he prescribes the following tonic and antipyretic mixture:

℞ Extract of chinchona..... ..... 1 drachm.
Sulphate of quinine.....15 grains.
Tincture of valerian..... 1 ounce. M.
Teaspoonful at a dose.

Tessier also applies cold compresses to the head and abdomen, and the patient is allowed 10 ounces of Bordeaux wine and one and a half pints of milk or broth in the twenty-four hours. He employs alpha-naphthol in preference to beta-naphthol because the latter is very much more poisonous; thus, to produce poisoning in a man of ordinary weight it is necessary that twice as much alpha-naphthol be given as of beta-naphthol. In consequence it is possible to give larger doses of alpha-naphthol without danger, and obtain thereby a greater degree of intestinal antisepsis. The cold baths which he recommends augment, in his opinion, the elimination of toxic substances in the urine, and the naphthol stops their production in the intestine.—*Med. News.*

GONORRHŒA.

Thomas R. Neilson states that the plan of internal treatment which he has pursued for so many years past, consists, first, during the earlier stages of the disease, in the administration of an alkaline sedative mixture, with the purpose of alleviating the scalding caused by urination, the tendency to frequent micturition and to chordee. The standard formula in his dispensary practice has been:

℞ Potass. acetat.....℥iij--℥ss.
Potass. bromid.....℥jss.
Acid. boric.....℥ij ℈ij.
Tinct. belladon.....ℳxxx.
Liq. potass. citrat... ....℥viij. M.
Sig. A teaspoonful in water every three or four hours.

Secondly, as soon as the symptoms are in a measure relieved, the administration of either oleoresin of cubebs and balsam copaiba in capsule, or of cubebs alone in powder, in teaspoonful doses, or finally, where chordee is troublesome, a combination of two parts by weight of powdered cubebs and one part of bromide of potassium, given in the same doses, and from three to four times daily.
—*Univ. Med. Magazine.*

TREATMENT OF DYSENTERY AND OXYURIS WITH NAPHTHALIN.

Dr. M. C. Minerbi, in the *Journal de Méd. de Paris*, May 31, 1891, speaks highly of the value of naphthalin in the treatment of both dysentery and oxyuris.

In the former instance the drug is used either in the form of suppositories or oily injections. The suppositories are prepared by the following formula:

℞ Cocoa butter
Naphthalin, aa.....10.0 grammes.
M.

If the ulcerations are seated so high up in the intestine that the suppositories cannot affect them, the author resorts to the following enemata:

℞ Olive oil.....20.0 grammes.
Naphthalin..... 5.0 grammes.
M.

In dysentery very frequently, owing to the existing tenesmus, these injections cannot be retained for more than half an hour. In such cases the injection should be repeated three or four times in twenty-four hours. Ultimately, however, the patient will be able

to retain the injection until it is absorbed. One great advantage of the treatment is that it does not produce constipation.

Rosbach employs naphthalin in dysentery in the following formula, which, however, Minerbi considers inferior to that advocated by himself.

℞
Boiling water.....100.0 grammes.
Naphthalin..... 5.0 grammes.
Decoction of marshmallow...500.0 grammes.
M. Sig. For one injection.

The mixture should be heated to 37° C. at the time of using.

The treatment is contraindicated in cases where the ulcerations extend to the small intestine, which is, however, rare.

Dr. Minerbi has also used naphthalin with considerable success in the treatment of oxyuris vermicularis. Eleven children, troubled with this parasite, were completely cured within eight days.

The formula employed was the following:

℞
Naphthalin.....1.0--1.5 grammes.
Olive oil..... 40--60 grammes.
M. Sig For one injection.

In treating the same trouble in adults a stronger formula may be advantageously employed, as follows:

℞
Naphthalin..... 5--6 grammes.
Olive oil.....60--80 grammes.
M. Sig. For one injection.

TREATMENT OF SYPHILIS DURING PREGNANCY.

Dr. E. Besnier, in the *Journal de Méd. de Paris*, May 31, 1891, claims to have found the following treatment for syphilis during pregnancy, both safe and efficacious.

I. *Tonic treatment.*—This consists of a good nourishing diet, syrup of iodide of iron and preparations of cinchona internally.

II. *Specific treatment.*—One pill of the following formula should be administered daily:

℞
Bichloride of mercury.....0.01 gramme.
Extract of opium.....0.005 gramme.
Extract of gentian..... .0.005 gramme.
Glycerin, q. s.
For one pill.

III. Simultaneously iodide of potassium should be exhibited in doses of gramme 0.5 to gramme 1.0.

This treatment should be continued during the entire course of pregnancy. An increase of the patient's weight is a sign of its success.

PYRIDINE IN GONORRHŒA.

℞
Pyridine..... .ɱv
Aq. distillat.....ʒiij
Sig. One injection daily.

—*Rademacker.*

TREATMENT OF OTALGIA.

℞
Chlorinated camphor..... 5.0 grammes.
Glycerin.....30.0 grammes.
Oil of sweet almonds.....10.0 grammes.
M. Sig. For the ear.

Place a small tampon of cotton, wet with this mixture, in the ear.—*Allg. Wiener Med. Zeitung.*

PURGATIVE PILL.

The following formula is recommended by Dr. Ball, in the *Journal de Méd. de Paris*, May 31, 1891, as constituting a pleasant and efficient purgative pill.

℞
Socotrine aloes..... 1.0 gramme.
Resin of scammony.....0.50 gramme.
Resin of jalap.....0.50 gramme.
Calomel.....0.50 gramme.
Extract of belladonna.....0.23 gramme.
Extract of hyoscyamus.....0.25 gramme.
Castile soap, q. s.
To make 40 pill. Dose, 3 to 5 pills a day.

FOR ECZEMA.

According to the *Centralb. für die gesammile Therapie*, the following formula will be found very useful in the treatment of eczema not of a chronic nature.

℞
Thymol..... 2.0 grammes.
Oxide of zinc
Starch aa.....25.0 grammes.
Lanolin.....50.0 grammes.
M. fiat unguentum, et Sig. Salve, to be applied to the affected parts.

SOLVENT FOR DIPHTHERITIC MEMBRANE.

℞
Pepsin.....ʒiss.
Acid. hydrochloric. dilut.....ɱj.
Aquæ destillat
Glycerini, aa.....ʒss. M.
Apply to the surface.

—*Canada Lancet.*

SALICYLATE OF SODIUM FOR CORYZA.

The *Journal de Médecine de Paris* gives the following:

℞
Salicylate of sodium
Syrup of orange } aa.....ʒss.
Peppermint water.....ʒvi. M.

At the onset of the attack a teaspoonful to a dessertspoonful should be given every three or four hours.

COCAINE IN ASTHMA.

C. R. D. Sylva (*Indian Med. Gaz.*, March, 1891) reports a case in which very severe attacks of asthma were in a few minutes entirely relieved by the following subcutaneous injection:

℞
Cocaine hydrochlor.
Morph. sulph., aa.....¼ gr.
Aquæ distil., q. s. M.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

EDWARD T. REICHERT, M. D.,

PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF PENNA.,

EDITOR AND MANAGER.

N. E. Cor. 13th and Walnut Streets,

P. O. Box 843. Philadelphia, Pa.

THE MEDICAL AND SURGICAL REPORTER.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent 3 months on trial for $1.

At the termination of the period of subscription, we will promptly discontinue sending THE REPORTER unless directed to the contrary by the subscriber.

Remittances should be made by draft, check, postal note, or money order payable to Edward T. Reichert.

THE POCKET RECORD AND VISITING LIST.

Two sizes. Prices to subscribers of THE REPORTER: For 30 patients a week (with or without dates), $1.00. For 60 patients a week (without dates), . . $1.25. Prices to non-subscribers, $1.25 and $1.50 respectively.

THE MODEL LEDGER.

Physicians who keep their own books will find this of great value. Sample pages sent on application. Price, $5.00.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If THE REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS.

Write in ink.

Write on one side of paper only.

Write on foolscap or legalcap paper.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be pleased to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

LEADING ARTICLE.

ANTISEPTICS IN THE TREATMENT OF TYFHOID FEVER.

Since the germ theory of disease has become established upon a firm scientific basis, the idea of treatment directed towards the neutralization of these specific organic poisons has naturally arisen. Although much progress has been already made in this direction in the treatment of many medical affections, it must be admitted that the results obtained in surgical practice are of far more practical importance than those arising from the use of antiseptics in non-surgical practice. To appreciate this we have only to glance over Hospital statistics, and find that whereas the mortality of all grave surgical procedures is immensely less, the same cannot be proven of those medical cases in which a living organism has been shown to be the essential cause. The cause of this difference in statistics is obviously the comparative ease of application of antiseptic treatment in surgical practice, and the insurmountable difficulties which at present prevent its use in cases where the seat of infection is the intestinal canal, and the blood itself.

While the ideal antiseptic has yet to be discovered, much good work has been done in this direction by many prominent clinicians, and perhaps no disease has been more vigorously attacked by antiseptic remedies, than typhoid fever. Indeed, it may be affirmed with some truth, that the idea of maintaining, as well as possible, intestinal antisepsis in this disease, occurs to almost every practitioner of the present day, and in the opinion of some, it is the method by which the best results can be obtained. No agent has yet been discovered which can affect the poison of typhoid fever in the circulating blood without being equally poisonous to the patient, so that, at present the questions are: Can we disinfect the intestinal canal, and thus favorably influence the course of the disease, does this method of treatment give better results than when other measures are adopted?

With the numerous modes of treating typhoid fever now in vogue, the answers to these questions cannot be authoritively made at present, but it is generally admitted that we possess certain antiseptic remedies which are capable of making the stools less offensive, of limiting somewhat the duration of the fever, and of lessening the abdominal tenderness and meteorism. Such agents are very commonly employed as adjuncts to other methods of treatment. But the effect of a *purely* antiseptic treatment upon the mortality needs further observation.

The maintainence of intestinal antisepsis depends largely upon the diet, which should be of such character as to be readily absorbed, and so contribute as little as possible to fermentation. The quantity of food is also most important, and no more should be given than can be readily assimilated, for, unless this is done, the food collects in the intestines, rapidly undergoes fermentation with the production of noxious solids and gases, and painful tympanites results. For this reason milk, diluted with lime-water, light watery soups, and proper amounts of pure water would seem the rational diet, since they are readily assimilated, and furnish plenty of liquid to carry away the waste products of tissue changes. Such a diet leaves a minimum of residue in the intestines, and hence is more suitable when intestinal antisepsis is aimed at.

The cheap drugs which have been lately used to promote antisepsis in the intestinal tract, are: naphthol, thymol, salicylate of bismuth, mercury in some form, carbinate of bismuth, chlorine, hydrochloric acid, turpentine, sulphide of carbon, boric acid, benzoic acid, carbolic acid, quinine, hydro-naphthol, and a number of others. The reported accounts of the use of any of these agents as an exclusive mode of treatment are too meagre to admit of any intelligent comparison of their relative values. They are all used for the same purpose, and none of them has proved entirely acceptable. Dr. J. Burney Yeo, Professor of Clinical Therapeutics, at King's College, London, has had very marked success with a mixture of chlorine and quinine, and in a late lecture (*The Lancet*, April 18, 1891) he highly recommends it, and strongly urges the expediency of some means being always adopted to secure as perfect an antisepsis as possible in the intestinal tract. To those interested in this subject, this lecture is well worth careful reading, as it details the history of the application of antiseptics in typhoid fever, as well as gives his own experience. Dr. J. Mitchell Clarke, has experimented favorably (*The Practioner*, Dec., 1888 and July, 1890) with *B*-naphthol and hydro-naphthol. His results were 1, "Reduction of the average duration of the fever; 2, Less offensive stools; 3, Less abdominal distention; 4, Early cleansing of the tongue and less dryness of mouth and lips; 5, Abscence of albuminuria; 6, Convalescence more rapid and strength less reduced; 7, Less risk of propagation of the disease; 8, Diminished tendency to secondary complications." Dr. Yeo states, in his lecture above mentioned, that M. Maximovitch prefers *A*-naphthol to *B*-naphthol, because it is three times less tonic, yet prevents the development of the typhoid bacillus when used in the proportion of 1 part in 10,000; and also that Dr. Moncorvo (*Satilliti*, Feb. 1890) has given *B*-naphthol to children in doses of gr. xv to gr. xxx, and that such doses were tolerated perfectly.

Liebermeister (Von Ziemssen's Cyclopædia of Practical Med.) urges the claims of mercury and iodine, giving the latter dissolved in a solution of the iodide potassium. Mercury he employs in the form of calomel. He found the mortality less in two hundred cases treated by calomel, than in a large number treated without it.

Experiences of leading physicians might be multiplied, but as they are too widely different as regards the conditions surrounding their cases, and the drug employed, to secure intestinal antisepsis, it is impossible to more than gain a general idea of the value of this treatment. That the idea of intestinal antisepsis is rational all admit, and it also may safely be said, that the experience already obtained from the use of antiseptics is highly encouraging. The end to be ob-

tained is most desirable, for by influencing the local conditian of the gut, the general toxæmia seems apparently proportionately lessened. Only time and an experience long enough to permit of the comparrison of reliable statistics of the use of the several remedies lately brought forward, can settle the question as to the best mode of securing the minimum amount of septic fermentation in the intestine, and, as has already been said, the kind and quantity of the food will prove an important factor towards this result. In this connection, the use of pepsin suggests itself, to complete the imperfect gastric digestion, and it is routinely given by Dr. W. H. Thomson, at the Roosevelt Hospital, New York, in conjunction with dilute mineral acids.

Since it has been proven beyond doubt that antiseptics play a most important role in the modern treatment of typhoid fever, it becomes every practitioner of medicine to consider carefully the means he shall employ to fulfill the indication which always is present in this disease. No one drug or mixture can be solely recommended for this purpose, and further, in many cases certain remedies are contra-indicated by the existing conditions of the stomach, but in all cases where no such contra-indication is present, an antiseptic of known value should constitute a part of the treatment, for its *specific effect* upon the bacillus. The favorable experience of chlorine and quinine by Dr. Yeo, of calomel aud iodine by Liebermeister and others, and the naphthol and hydro-naphthol by Clarke, (as well as the reported value of many other antiseptic remedies) allows of considerable latitude in the choice of the drug to be employed. It is to be hoped that these antiseptics will be given a larger trial in the Hospitals of this country, side by side with other modes of treatment, including the treatment by cold water baths, as introduced by Brand, and it is needless to say, these statistics obtained in this way, from single large Hospitals, will be most valuable in determining which drug, of those already employed, will most adequately fulfill the purpose of limiting to a minimum the production of toxic ptomaines, or similar substances, and thus prevent their introdution into the already poisoned blood.

All our knowlege of the pathological conditions which exist in typhoid fever, suggests persistent effort towards this line of treatment, as being the most rational and direct method of combating the disease, and although the remedies as at present used may fall far short of perfection, still, as has been said, the experience of acute observers proves how much room there is for hope in this direction.

Enough proof of the efficacy of the antiseptic treatment of typhoid fever is forthcoming to warrant the assertion that it should be given a high place among the measures usually employed.

Book Reviews.

DIGESTION AND DIET.—By Sir William Roberts, M. D., F. R. S., Philadelphia. Lea Brothers & Co., 1891.

This book embraces, in one volume, all the contributions made by the author, at various times, to the subjects relating to Digestion, Dietetics and Dyspepsia. It is arranged in four groups or sections.

Section I., is occupied in the consideration of *digestion and the digestive ferments.*

Under the head of "The Preparation of Artificial Digestive Juices," the author records the results of a series of experiments made, with the object of ascertaining the best preservative of artificial degestive juices, which either had little taste and smell, or one which was volatile and could be got rid of by vaporisation. The investigations were begun with the ultimate view of obtaining a solution of these ferments which could be administered as a medicine by the mouth, or which could be employed in the preparation of artificially digested food.

After a number of trials, these solutions were adopted: Dilute Spirit; Boracic Solution, and Chloroform Water. Preferance being given to the first.

Section II., deals with the subject of *dietetics*, and it contains much useful information of undoubted value to the busy practitioner.

Section III., treats of the *preparation of food for invalids.* As this is a matter of no little importance to the general medical man,

and has considerable bearing upon the success of any treatment, the author has justly seen fit to occupy considerable space to the consideration of such topics as the preparation of ordinary food for invalids; the preparation and use of artificially digested food, the use of malt, and especially of malt infusion, for the free digestion of starch food, etc.

SECTION IV. on *dyspepsia*, relates to the so-called acid dyspepsia of otherwise healthy persons.

The entire work is well worthy of the efforts of its distinguished author, and not only will amply repay the time spent in a careful perusal of its contents, but it often will be found a very convenient book to have in the library for ready reference.

MEMORIAL SKETCHES OF DR. MOSES GUNN. By his wife.

A book of 380 pages, with the above title, is filled with a well-written description of the personal attributes, and scholarly attainments and professional success of a man who rose to the first of American surgeons.

Born in East Bloomfield, N. Y., April 20, 1822, of good parentage, he was liberally educated, graduating in medicine in 1846, and the same year commencing lectures upon Anatomy at Ann Arbor, which he continued until the founding of the medical department of the University of Ann Arbor, Michigan. He was then elected Professor of Surgery, and held the chair until 1867, when he resigned to accept a similar position in the Rush Medical College, Chicage. Since then his reputation has extended to every part of the country as an eminent teacher.

These sketches, by his wife, will undoubtedly come to his many personal friends as a delightful reminder of the man, containing, as they do, many little stories which cannot fail to perpetuate the memory of his many virtues. To others, also, who have never viewed a doctor's life from the standpoint of his wife, the book will be worth reading. None can fail to gather some lesson in its pages, regarding the successive periods in medical life, and over all the pages is the pathos of a wife's description.

EUCALYPTUS DISINFECTANT.

The oil may be dissolved in alcohol, 1 in 20; it may be used in powder, 2 parts oil, 10 borax, 60 infusorial earth or other cheap absorbent material; even sawdust would answer readily and effectively.

PERISCOPE.

THERAPEUTICS.

THE PLACE OF MERCURY IN THERAPEUTICS.

Dr. E. P. Hurd, in the *N. C. Med. Jour.* reaches the following conclusions:

1. Mercury must still take the palm over all other remedies in the treatment of secondary syphilis. Here the choice is between two evils; but the syphilitic poison is a greater blood-spoiler than mercury when judiciously administered; and, in antagonizing and destroying the virus of syphilis and preventing its ravages on the blood, mercury becomes a genuine reconstituent tonic. The mercurial treatment is not to be commenced *until the syphilis has declared itself*, and is to be instituted only in the secondary stage.

2. Mercury (under the form of calomel) has no place in medicine as an antiphlogistic or alterative, and its employment in fractional doses in combating inflammations, whether acute or chronic, should be absolutely discarded.

3. Calomel has a limited usefulness in infantile therapeutics, but principally as a gastric sedative and as a thorough antiseptic cathartic.

4. Calomel is an efficient purgative, stimulating the secretions of the intestines and liver and promoting intestinal peristalsis; it remains so long unchanged in the alimentary canal that it exercises a local antiseptic and sedative effect, and hence proves valuable in many morbid states of that canal. As a cathartic it is good to clear the *primæ viæ*, especially when no other cathartic can be borne, owing to irritability of the stomach; in the onset of some inflammatory or febrile diseases it may have a useful depurative and even derivative effect.

5. In the ordinary "bilious" complaints calomel has a place which is entirely subordinate to other more rational and hygienic modes of treatment.

ANTIPYRIN IN PLEURITIC EFFUSIONS.

At a meeting of the Société Nationale de Médecine de Lyon, on April 20th (*Lyon Médical*, May 10th, 1891,) M. Clement presented a communication on the effect of antipyrin in pleuritic effusions. He said his attention had been called to the subject three years before, and his conclusions were based on observations made in some twenty cases.

When a patient comes under his care with signs of pleural effusion he marks the upper limit of dullness with lunar caustic, and can thus note the slightest variation in the amount of the fluid. Whether fever be present or not, he at once administers antipyrin without any other medication whatever. In all cases there was, on the following or at latest the day after, a marked reduction in the height to which the dulness reached. In some cases the dullness disappeared after forty-eight hours' treatment, and in two or three the fluid was completely absorbed in twenty-four hours. In no case was the effect delayed beyond four days. The dose given was, as a rule, 6 grammes a day, 1 gramme being given every four hours. After absorption of the fluid the treatment should be continued for some days longer, in order to prevent relapse, the daily dose being, however, reduced to 4 grammes. The cases treated by M. Clement included examples of acute pleurisy *a frigore* and latent pleurisy; both forms yielded readily to treatment, the effect being rather more rapid in the latter than in the former. The treatment failed when the effusion was purulent or bloody. In cases in which the whole pleural cavity was filled with fluid, M. Clement did not feel himself justified in trying the antipyrin treatment, but performed thoracocentesis without delay. With regard to the *modus operandi* of the remedy, he says that even when resolution was almost immediate, nothing like diuresis took place, the amount of urine being increased only from 100 to 200 grammes in the twenty-four hours. In some patients no diaphoresis was observed; in others it occurred after resolution had taken place. Resolution occurred as rapidly in the non-febrile as in the febrile cases. M. Clement thinks antipyrin has a specific action on nearly all inflammatory processes, and it is to this that he attributes its beneficial effect in pleural effusions.—*Brit. Med. Jour.*

SALOL IN TYPHOID FEVER.

Dr. Frank P. Wilson, writing in the *Southern Clinic* for March, 1891, says that he has found salol to be a very satifactory remedy in rheumatism, but that in infantile diarrhœa he has also found its administratin attended with good results. The use of one grain of the drug every four hours promptly checked the diarrhœa, and the continued administration of the remedy two or three times a day for a few days effectually prevented a relapse. In typhoid fever he had had very favorable results, and in all cases in which he had given it from the onset of the disease there was no tympanites, no diarrhœa, no dry tongue, nor sordes on the teeth. Even when the treatment was begun late in the course of the disease, when the symptoms were already grave, the whole condition was changed for the better within two days by two or three grain doses of salol every four hours. He did not believe that the duration of the fever was shortened at all, but all the symptoms were ameliorated, delirium was kept away, and the patient preserved a desire for food, usually waiting anxiously for the milk hour to come around. One grain of salol was given every four to six hours, except when there was severe diarrhœa, when the dose was doubled for a short time.

CACTINA: A NEW AND VALUABLE CARDIAC STIMULANT.

Dr. O. M. Myers, has contributed to the *N. Y. Med. Jour.*, a very suggestive article on cactina, which is the proximate principle of the plant *Cereus grandiflora* (the night-blooming cereus; Ger., *Königin der Nacht*), natural order *Cactaceæ*, which is indigenous to tropical America. The active principle has been successfully isolated by Frederick W. Sultan, Ph. G., the well-known pharmaceutical chemist of St. Louis. For this purpose he employs the young flowers and stems of the Mexican variety, in which the yield is greater and more constant than in other species. It is thus described: "The stem is branching, fleshy, green, and five or six angled. The angles are beset with clusters of five or six short radiating spines. The numerous imbricated calyx lobes are linear, acute, brownish, the inner ones yellow. The flowers, which open in the night, are very fragrant and produce an orange-colored, internally white berry the size of an egg. The flower of this species is decidedly the richer in active principle and yields 0.021 to the 1,000, or over two per cent."

Physiological Action.—Locally, cactina is absolutely non-irritant, a ten-per-cent. solution applied to the conjunctiva producing no noticeable effect.

Therapeutic doses. in man and animals, produce an acceleration of the pulse and a rise in the arterial pressure.

Toxic doses, in animals, produce primarily an acceleration of the pulse-rate and a rise in the arterial pressure, but, secondarily, notably diminish both. The cardiac pulsations become arrhythmical and finally cease,

the heart being arrested in systole. The systoles, just before death, become very incomplete, probably due, as will be shown below, to a condition of superirritability of the cardiac ganglia. Death is preceded by tetanic and clonic convulsions, due to overstimulation of the motor side of the spinal cord. That the convulsions are not of cerebral origin is evident, as they occur after section of the cord in the upper cervical region. The motor nerves remain unaffected, for, after the death of the animal, galvanization produces contraction of the muscle. Cactina is therefore a powerful *motor spinal stimulant.*

SUMMARY.—Cactina in therapeutic doses—

1. *Increases the musculo-motor energy* of the heart, probably through its influence upon the intracardiac motor and accelerator ganglia, in consequence of which the cardiac impulses become regular and much stronger.

2. *Elevates the arterial tension,* increasing correspondingly the height and force of the pulse wave. This is produced by—*a*, increased cardiac action; *b*, stimulation of the vaso-motor center at the base of the brain.

3. *Influences the nervous system* by its direct action upon the motor centers of the spinal cord, thus increasing the reflexes and elevating the general nervous tone. Herein cactina resembles strychnine, and other points of similarity are evinced by clinical observation.

Therapeutics.—It logically follows, if conclusions as to its physiological action are correct, that in cactina we have a powerful cardiac tonic-stimulant. Clinical observation teaches that its greatest value is manifest in functional disturbances of the heart, as simple dilatation and cardio-muscular atony (resulting from deficient innervation and nutrition) without organic lesions. If valvular disease exists, accompanied with dilatation. In conditions of cardiac and general muscular relaxation with impaired nerve energy, and in case of "irritable heart," "tobacco heart," etc., the drug accomplishes excellent results; probably by, *a*, stimulation of the spinal motor-nerve centers; *b*, constantly stimulating the heart muscle to action and thereby increasing its nutrition and development.

A special indication for its use is during the critical periods of adynamic fevers, as it combines the elements of a heart and spinal motor stimulant.

Unlike digitalis, cactina may be administered continuously without fear of exciting gastric disturbance, and the objectionable cumulative action of the former drug is entirely absent. In short, cactina may be employed with benefit in all varities of functional cardiac and circulatory disturbances and in organic heart disease, except in cases of *mitral stenosis,* where digitalis is to be preferred on account of its power of prolonging the diastolic period, thus affording the ventricle power and time to entirely empty itself. *Per contra* in *aortic insufficiency,* the short diastole produced by cactina allows no time for regurgitation of blood into the ventricle, whereas digitalis, by prolonging the diastolic period, favors just what we should seek to prevent.

Preparations of *Cereus grandiflora, C. Bonplandii, C. McDonaldii,* and other allied varieties, have long since been employed in medicine, but the results have been uncertain. This is accounted for by the fact that the yield of active principle varies greatly in the different species of the plant and in the same species in different habitats. Under such circumstances the strength of preparations would necessarily be so inconstant as to make them unreliable for use. The same may be said of many other valuable drugs, such as cannabis indica, ergot, etc., of which two preparations of the same strength can hardly be found. The difficulty has been entirely obviated in the case of *Cereus grandiflora,* for, by the isolation of its active principle, we have the means of employing it in constant and definite quantities.

THE TREATMENT OF CHRONIC ATROPHIC RHINITIS (OZÆNA).

As Dr. De Havilland Hall, writes in the *Med. Press*:

Though local treatment is all important in atrophic rhinitis, it is well before commencing it to see if there be any underlying general condition of ill-health which needs correction. If anæmia be present the combination of ten grains of the ammonio-citrate of iron with three minims of arsenical solution given thrice daily exercises a beneficial effect. If there be any tendency to phthisis cod-liver oil should be administered. The iodides do not seem to have any good effect in the ozæna due to atrophic rhinitis. The essential point in the local treatment is the thorough cleansing of the nasal cavities. This may be effected in three ways:—(1) By means of the douche. (2) By the use of the anterior and posterior syringe. (3) By spraying. At one time I used the douche almost exclusively, but of late years I have entirely given it up. Several cases of otitis media due to the fluid passing up the Eustachian

while the douche was in operation have been recorded, and though I had had no personal experience of this accident it was one of the reasons which induced me to discontinue this form of treatment. Pins' modification of the douche to which Dr. Ball has recently directed attention seems to obviate this objection. The anterior and posterior syringe answers fairly well in the less severe forms of the disease, but where crusts have collected on the sides and roof of the nasal passages the only effectual method of washing them away is by means of a spray emitted with considerable force from the apparatus. For those who prefer the douche or the syringe the following solution may be employed.

℞

Sodii bicarb., Boracis, aa.....ʒj;
Glycerini acidi carbol.....ʒij;
Aquam, ad.....Oss.

This is known as Dobell's solution.

Bayer, however, states that carbolic acid is not to be recommended locally because it often completely destroys the power of smelling in those cases in which it has been preserved. Chlorate of potassium, or liquor potass. permanganatis may be substituted for the borax, great care should be taken that the solution used should be of a suitable temperature.

I have found "Listerine," an American preparation containing thyme, eucalyptus, and other essential oils, together with benzoboracic acid, a most serviceable and pleasant disinfectant. It may be conveniently employed in Dobell's solution instead of the glycerine and carbolic acid in proportion of one or two of listerine to ten of the lotion. As on account of the chronicity of the disease the employment of expensive drugs, or any drugs at all for the matter of that, is a matter of serious consideration to persons of limited means, it is often necessary to use the cheapest preparations. For this purpose common salt, two drachms in half a pint of water, or chlorate of potassium one drachm, or liq. potass. perm. one drachm in same amount of water will be found very useful.

My mode of treatment is first to soften and loosen the crusts as much as possible with a simple saline spray. For this purpose I usually employ bicarbonate of sodium, chloride of sodium borax, of each thirty grains, white sugar, forty-fives grains in half a pint of warm water. This is practically the formula introduced by Morell Mackenzie. If on rhinoscopic examination hardened masses still adhere to the mucuos membrane they may be cautiously removed by means of the nasal forceps, or by the use of the anterior or posterior nasal syringe. The patient should be told to use the spray at least night and morning, sometimes three times a day may be necessary, and to come again in a week's time. If on the second interview the nostrils are found to be free from crusts and fairly sweet, the patient is to be directed to continue the same treatment. If crusts are again met with they should be removed as on the first occassion. The simple saline spray may be continued for some weeks, and if there is no evidence of distinct improvement it will be well to make a change. I have found the addition of listerine to the alkaline spray useful in diminishing the fœtor from the nose and acting as a mild stimulant. If a more powerful disinfectant is required Dobell's solution may be used, and the amount of carbolic acid increased if necessary, also weak solutions 2 to 5 grains of sulphate of zinc, alum, or nitrate of silver will at times be found useful. The permanganate of potassium formula or creolin 1 to 500 up to 1 to 100 is useful as a change. After thorough cleansing of the nostrils insufflation may be employed. For this purpose I have used iodoform, idol. or boric acid. Recently aristol (the iodide of thymol) has been highly recommend. Many other combinations have been advised, but whatever is used it must be distinctly understood that it is not so much the particular solution employed as the thoroughness with which the process of cleansing the nostrils is carried out which conduces to the cure. Again, it is very desirable to ring the changes on the solutions employed. After thoroughly spraying out the nasal cavities I have found smearing the interior with oil of eucalyptus and vaseline (a drachm to the ounce) servicable, as it as it appears to prevent the mucous membrane from becoming dry. The vaseline should be warmed and applied by means of a camel's hair brush. Another plan is to spray out the nostrils with one of the liquid paraffins, *e. g.*, paroleine.

In intractable cases Gottstein's tampon is very useful. To obtain the best effect the plug of cotton wool should be in contact with the whole of the interior of the nostril. The plug acts as a stimulant to the mucous membrane and so keeps up a certain amount of water discharge, thereby preventing the formation of crusts.

Ruault recommends the following method of treatment:—

The nostrils are to be washed out with a solution of bicarbonate of sodium. They

are then to be painted with naphthol-camphor, which consists of one part of naphthol to two of camphor with a variable quantity of fluid vaseline according to the sensitiveness of the patient. The drying of the mucous membrane is prevented by frequently spraying the nostrils with fluid vaseline with the addition of naphthol-camphor (1 to 10,000 up to 1,000). Later on, to replace washing out by means of inhalation of vapor benzoini.

Resorcin, the galvanic cautery, the constant current, and innumerable other plans of treatment have been suggested; the very number of drugs recommended being a proof that no one of the number can claim to be a specific. I have, however, I think sufficiently described the best plans of treatment in vogue, and I need only add that I shall be extremely thankful for some new hints for combatting this troublesome affection.

MEDICINE.

A CASE OF ANGINA LUDOVICI.

Dr. T. Arnallt Jones, in the *Lancet*, says: A man aged fifty years was seized early in the morning with a severe prolonged rigor, dysphagia, and great pain in the mouth and submaxillary region. I first saw him at 9 A. M. His temperature then was 105° F.; pulse 150; respiration noisy, due to swelling up of tissues about the laryngeal orifice; headache, prostration, and covered with cold sweat. On looking into the mouth the tongue was seen pressed up against the palate by the swollen sublingual tissues; and so considerable and firm was this sublingual cellulitis that a spatula could only with difficulty be passed between the tongue and palate; depressing the tongue was quite out of the question, consequently the fauces could not be inspected. The patient could neither swallow nor speak, and it is surprising how he was able even to breathe as well as he did. There was albuminuria to the extent of one-sixth. The sublingual tissues were scarified, and leeches applied below the jaw. Poultices and steam inhalations were ordered. These measures relieved the pain somewhat, and in the evening the temperature fell to 103°, but the dysphagia and dyspnœa continued. The following morning the temperature was 104°. Submaxillary œdema increased, with commencing redness of the skin, and cellulitis was spreading down the neck between the sterno-mastoids. The patient was feebler, and the dyspnœa greater. To relieve tension and drain the tissues two deep incisions were made in the middle line of the neck—one an inch long above the hyoid bone, which reached well down to the floor of the mouth; the second, two inches long, over the cricoid cartilage and thyroid isthmus. The tissues cut through were swollen and sodden, and foul, serous blood-stained fluid poured out from both. These incisions gave marked and speedy relief, and the patient was very shortly able to swallow and speak distinctly. Hot fomentations of tenax were applied, and quinine and aconite administered. Evening temperature 101°; great relief. Brandy mixture ordered.—Third day, 9 A. M.: Temperature 100°; not quite so well. 1 P. M.: Temperature 104°; swelling and redness over upper part of sternum; leeches and poultices applied. 11 P. M.: Temperature 101°; swelling over the sternum disappeared; feels much better.—Fourth day: Temperature 100°; much improved; wounds discharging.—Fifth day: The patient up and about; feels much better, but very weak. From this to the seventeenth day the patient improved, the incisions healed, and he became practically well. Angina Ludovici is attended by a considerable mortality, and is fortunately not of common occurrence. The relief and arrest of symptoms afforded by the incisions and leeching were so marked that they should form the essence of treatment in this disease, and to be of service incisions must be made early in the case. It is too late to cut when the tissues of the neck are sloughing and the cellulitis is spreading down to the chest and the patient showing signs of profound blood-poisoning. There was no local condition, such as a carious tooth or ulcer of the mouth or pharynx, to account for the onset of the angina; but the patient's occupation, that of a butcher, suggested the possibility of his having absorbed or been inoculated with some animal or specific poison.

UNUSUAL COMPLICATIONS OF ENTERIC FEVER.

Finlayson, in the *Amer. Jour. of Med. Sciences*, gives instances of nine unusual complications of typhoid fever.

1. Abortive attacks not free from danger. In an epidemic of enteric fever in the Glasgow Western Infirmary, several of the inmates had slight febrile attacks lasting a few days and ending in recovery. One patient had an attack in which the fever lasted but

two days; fifteen days after the cessation of fever she had a relapse, which proved fatal in four weeks.

2. Carbuncle and death following an obscure illness, with little or no pyrexia. A gentleman, in whose house typhoid fever occurred, was ill and out of sorts for two weeks; his temperature never rose above 99°; this was followed by a carbuncle, which caused death from septicæmia.

3. Uræmic convulsions. A case of supposed typhoid fever, with highly albuminous urine, which contained hyaline and granular casts, was seized with convulsions, evidently uræmic, and died on the seventeenth day.

4. Grangrene of the sole of the foot. One month after the fever began in this case, a gangrenous spot appeared on the sole of the foot, where there was no pressure; the case developed cystitis, and died in the sixth week.

5. Alarming nervous disturbance with the subsidence of pyrexia. A case with relapse ran a course of four weeks; there were but few nervous symptoms; but as the fever declined, delirium set in, low and muttering, with terrible visions; a peculiar tremor of the head and complete sleeplessness also occurred.

6. Double periostitis with necrosis. A case with relapse lasted five weeks; over two weeks after defervescence, there was sudden elevation of temperature, with pain in both tibias; necrosis followed, and the patient was under treatment at the end of the eighth month.

7. Gangrene of the lung. Consolidation of the base of one lung took place in the fourth week of the fever, which was followed by gangrene of the lung. Death occurred in the eighth week.

8. Paralysis and anæsthesia of the limbs after recovery. Three weeks after recovery from typhoid fever, numbness and stiffness of the legs supervened, followed by weakness of the arms. Great wasting of the muscles occurred; there was complete inability to stand. Recovery took place under treatment with tonics and electricity.

9. Concurrent development of enteric fever and tubercular meningitis. A young man was taken suddenly ill, with symptoms of meningitis; the meningeal symptoms cleared up and the case ran a course of typical typhoid fever. During the course of the fever peculiar urinary symptoms arose; fever subsided, but progressive emaciation occurred, and signs of meningitis again appeared. He died of meningitis in about one month from the beginning of his illness. The *post-mortem* showed typical tubercular meningitis, and partially healed ulcers of Pyer's patches, which were distinctly *not* tuberculous.—*Univ. Med. Mag.*

HEMIOPIC HALLUCINATIONS.

With reference to the paper on this subject recently published by Dr. Peterson of New York, of which a notice appeared in our columns, Dr. Schweinitz in the *New York Medical Journal* refers to a case published by him as one of a series in 1887 in the *Journal of Nervous and Mental Diseases.* The patient was a young man of twenty-nine, who had several convulsions and was the subject of optic neuritis with left homonymous hemianopsia. He became mentally deranged and was sent to an asylum. Preceding the onset of hemianopsia he had visions of chairs, tables, and other common things floating about. Although he was quite rational at the time, he was unable to state whether those visions disappeared coincidently with the onset of the hemianopsia or persisted for a time. He died afterwards in the asylum, and at the necropsy there was found a gummatous infiltration at the base of the brain pressing on the right optic tract. The author is unable to state definitely that there was no affection of the occipital lobe, and he regards the case as one of the class described by Dr. Peterson in which the hemiopic hallucinations are simple and transitory.—*Lancet.*

TEMPERATURE IN EPILEPSY.

M. Bourneville (*Revue de Médecine*, April, 1891) considers the subject of temperature in epilepsy under the following heads:—(1) During the epileptic attack isolated epileptic fits cause the temperature to rise from $\frac{1}{10}$° to 1½° C.; (2) in a series of fits with intervals more or less long, during which consciousness always returns, the temperature behaves as in the first group—between this class of case and the status epilepticus there are intermediate conditions; (3) during the status epilepticus, characterized as it is by (*a*) an incessant repetition of the fits, so that often one fit begins before the other ends; (*b*) a stupor varying in degree, but which may end in absolute coma with no return of consciousness; (*c*) a hemiplegia more or less complete and transient; (*d*) frequency of the pulse and respiration, and especially by (*e*) a considerable rise of temperature persisting between the fits. M. Bourneville divides the epileptic state into two periods (1) con-

vulsive, (2) meningitic (*période méningitique*). After the temperature has risen considerably, corresponding to the convulsive stage, matters improve and the temperature falls. Then appears this meningitic stage, which may terminate in death or recovery. The status epilepticus does not always establish itself at once, and this is especially the case in partial epilepsy. The internal or central temperature (for example, in the rectum) was taken in all these cases. M. Bourneville gives many examples illustrating these views.—*Brit. Med. Jour.*

THE PREVENTION OF PHTHISIS.

The high rate of mortality from phthisis induced the State Board of Health of New Hampshire to secure the opinion of the physicians of the State upon certain points in connection with the disease, such as its cause, frequency, preventability, treatment, etc. To this end blanks were sent to all physicians of the State asking them to answer nineteen stated questions. The returns were exceedingly complete, and as reported in the recently issued annual report of the State Board of Health, make interesting reading. A summary is almost impossible but the Board presents the following:

The chief causes and the preventative measures to be employed in the disease may be summarized, in the light of our present knowledge of the disease, as follows:

1. Pulmonary phthsis is the most fatal disease known to civilization.

2. The *bacillus tuberculosis* is generally believed to be the cause of the disease.

3. The disease, when developed after the first years of childhood, is acquired and not inherited, although there may be an inherited predisposition which renders the subject incapable of resisting the invasion of the bacilli.

4. The disease is liable to appear at any period of life.

5. That there is great danger arising from the use of tuberculous meat and milk. From the evidence which has been gathered we are led to believe the liability to infection from these sources is very great and to insure public protection in this particular the State should exercise a careful supervision of our milk and meat supplies.

6. That the greatest danger of infection is from the sputa of the consumptive. For this reason, when confined to the house, a spit-cup or spittoon should be used, and when upon the street a handkerchief to receive the expectorations. The spit-cup or spittoon might perferably contain a disinfectant, but if these vessels are frequently and thoroughly cleansed with boiling water, disinfectants are not an absolute necessity. The handkerchiefs should be immersed in boiling water at least once daily before the sputum has become dried.

7. No person should occupy a sleeping room with another who has tuberculosis, although many persons escape infection under such conditions.

8. The eating utensils of a consumptive should be washed in boiling water, and care should be exercised that the same glasses, spoons, etc., are not, before being washed, used by children and others. The patient should avoid kissing others or placing in his mouth any article likely to be used or handled by others.

9. The dejections of consumptive patients in cases where the bowels are affected should be thoroughly disinfected.

10. Perfect cleanliness of the apartments occupied by consumptives should be urged in all cases. The bed-linen, towels, etc., should be very frequently put through the operations of the laundry, while the walls should be frequently cleansed and dressed anew. In fact the whole question of restriction may be expressed in one word "cleanliness."

SURGERY.

CONSERVATIVE SURGERY OF THE GALL BLADDER.

Prof. E. Rose, of Berlin, writes: The principles which should actuate us in the treatment of affections of the gall bladder are laid down by the author as follows:

Cholecystectomy (extirpation of the gall bladder) need not, as a rule, be resorted to, except in cases of malignant or complete degeneration. It may be replaced by local treatment of the gall bladder, and measures calculated to restore the outflow of bile into the cystic duct.

Another reason against the utility of extirpation, is the possibility that the occlusion of the cystic duct may be followed by dilatation of the biliary passages.

Cholecystotomy with immediate suture and closure of the abdominal wound, is capable of affecting a cure in from two to three weeks, without dangerous complications, as is shown by the author's experience.

In chronic supuration of the gall bladder, with occlusion of its efferent duct, obliteration of the organ can sometimes replace an extirpation.

Cholecystostomy, or the establishment of a biliary fistulæ, is a palliative operation, and is of especial value, when neither extirpation nor removal of the obstruction in the cystic duct is possible. It is not a radical operation, for, owing to the loss of bile, these fistulæ rapidly produce exhaustion.

Biliary fistulæ sometimes heal spontaneously without apparent cause and sometimes after removal of the cause.

In appropriate cases we are warranted in opening the gall bladder, and for that purpose even perform a laparotomy and search for, and, if possible, remove the obstruction in the gall bladder.

We can best inform ourselves regarding the condition of the gall bladder and the permeability of the bile passages by digital exploration and catheterization of the ducts.

After the obstruction has been removed, if the gall bladder is healthy, it may be immediately sutured and returned to the abdominal cavity; or if this is prevented by adhesions, we may establish a safety valve by the formation of a biliary fistulæ which is allowed to close gradually.

It is only when the cystic duct is permanently closed that we have to decide between obliteration, extirpation or cholecystostomy. —*Deutsche Zeitschrift fuer Chirurgie.*

THE SURGICAL TREATMENT OF NEUROSES.

Little by little gynæcologists are gaining courage and endeavoring to extend the scope of their favorite operation, that of the removal of the uterine appendages. Not content with the rich harvest of ovaries afforded by uterine myomata and chronic inflammatory affections of the annexes, they yearn to emasculate—or rather effeminate—women whose only offence is that of being unnecessarily irascible during the menstrual period. They loudly proclaim their intention of proceeding with the utmost caution, and well they may, for the result so far has not been very encouraging in spite of the one or two apparent successes recorded by the Napoleon of ovarian surgery. The consensus of opinion, on the part of psychologists and gynæcologists alike, is distinctly adverse to the idea that any benefit is likely to be derived from the operation in the majority of cases of insanity in females, even when the condition is exasperated by the menstrual function. There is, of course, this to be said, that no harm is done even in case of failure, because it is to the interest of the community that these women should not procreate, but neither public nor professional opinion is as yet prepared to admit this argument to possess even a negative value. Another point is, that a speculative operation of this kind would not justify incurring even the smallest risk to life. Fortunately, we are assured by Mr. Mayo Robson, that so far as the mortality of the operation is concerned, it may be treated as a *quantité négligeable.* It is hardly safe to be too dogmatic in refusing recognition to the operation when practised for the relief of mental conditions assumed to be more or less intimately associated with menstrual excitement. Professional opinion has undergone such a radical change during the last few years in respect to this branch of surgery that the prophet's role is an uncomfortable one, and is, moreover, one which we are by no means anxious to assume.—*Med. Press.*

PRIMARY RESECTION OF GANGRENOUS INTESTINE IN HERNOITOMY.

In the *Beitrage zur klinischen Chirurgie,* Bd. 7, Hft. i, Dr. F. Krumm, of Heidelberg, discusses the indications and contra-indications of primary resection with apposition of the divided portions of intestine by circular suture in cases of gangrenous hernia. The question has been much discussed since the adoption of antiseptic methods into practical surgery, and with many German surgeons of great authority it is still a disputed point whether such treatment be justifiable or not. The views expressed in this paper are based on a study of fifteen cases of gangrenous hernia, which were treated in Professor Czerny's clinic in the course of a period of nearly twelve years. In nine of these cases an artificial anus was established, and in four the gangrenous intestine was cut away and the divided portions of the intestinal canal were brought together by circular rows of sutures. The first mentioned plan of treatment resulted in complete recovery in five cases, and was attended by fatal results in the other four. Of the cases of primary resection, three were successful, in the fourth case death, which occurred on the operating table, was due to asphyxia. Dr. Krumm points out that the surgeon, in dealing with gangrenous hernia, has to decide between one or other of these two operations. The fact that in fifteen cases of gangrene of intestine in connection with strangulated hernia Czerny, who is an advocate of primary resection and circular suture, had recourse to the formation of artificial anus affords a proof that in many instances of this compli-

cation there can be no room for choice between the two methods. The latter operation alone is indicated under the following circumstances: Gangrene involving not only the strangulated intestine, but also the sac and the surrounding structures; when the patient is in a condition of extreme collapse; when the strangulation has been much prolonged and has caused severe symptoms and a large accumulation of fæcal matter in the intestinal canal. With regard to primary resection, Dr. Krumm holds that recourse to this method is justifiable in recent cases of strangulated hernia, especially cases of so-called elastic strangulation of intestine, in which the tendency to gangrene is due to congestion of the blood vessels of the strangulated loop, and not to accumulation of fæcal matter, provided also the mesentery be not too much and too extensively constricted. Cases of fæcal strangulation are not altogether excluded, but here, it is held, much judgment is required and a careful selection must be made. In such cases primary resection is not to be taken into consideration unless the strangulation has been of brief duration and the symptoms of intestinal obstruction are very severe. Exhaustion and collapse, and well-marked symptoms of peritonitis, are decisive contra-indications to such treatment. It is also contra-indicated in cases of advanced phlegmon of the structures surrounding the hernial sac and of the anterior wall of the abdomen. In such cases an artificial anus is already in process of development, and firm adhesions are probably already well established between the intestine and the hernial rings. Moreover, in such instances perfect asepsis cannot be attained. On the other hand, partial gangrene of the normal sac is not a contra-indication, since by removal of all the gangrenous parts and by energetic disinfection after provisional occlusion of the abdominal cavity a fairly aseptic field of operation may be produced. As primary section demands, as conditions of its successful performance, not only an experienced operator but also skilled assistance and a very strict attention to all the details of the antiseptic method, it ought as a rule, Dr. Krumm suggests, to be restricted to Hospital practice. Notwithstanding the many contra-indications which are carefully and candidly discussed in this paper, there still exists, it is stated, a certain class of gangrenous hernia in which primary resection of intestine and circular suture may be regarded as the proper method of treatment. With regard to the comparative mortality of the two methods of dealing with gangrenous hernia, it is pointed out by Dr. Krumm that the most recent and complete statistics show that the percentage of deaths is rather smaller after primary resection than after the formation of an artificial anus.—*Brit. Med. Jour.*

GYNÆCOLOGY.

MINOR UTERINE SURGERY.

The Uterine Sound.—On the whole, it had been better for womankind had this instrument never been invented. For the application of the electric current it has its uses, and in an occasional case where one is uncertain as to the connection of the uterus with a given tumor it may possibly give some definite information. For the purpose of measuring the depth of the uterine cavity, or for locating the position of the fundus, as it is generally used, it is absolutely superfluous. Any one who is forced to use it for these purposes, unless it be in rarely exceptional cases must confess to himself his lack of even an ordinary amount of manual dexterity. For replacing a displaced womb it is a dangerous instrument, and its use is very painful. A movable uterus can be invariably replaced by bimanual manipulation, with the patient on the back, or in the knee-chest position, with the aid of a tenaculum and a repositor. If the organ is adherent it no longer comes under the head of simple uterine disease, and should then be dealt with by other and safer procedures. The uterine sound may be used with perfect safety in careful hands; but, as ordinarily employed, it is capable of causing considerable traumatism, and of carrying septic material into the uterine cavity.

Dilitation.—This operation is one which has been much abused. It is capable of much good or much harm, depending upon whether it is used carefully and in suitable cases or not. Personally I have never had any permanent bad results follow its use. On the contrary, I have seen severe dysmenorrhœa relieved and even permanently cured; in not a small proportion of cases have I observed pregnancy follow dilatation. Patients have come to me suffering from a pelvic inflammation following a dilatation performed by others, but everything pointed to the fact that the pelvic disease had existed first and that the operation had been performed probably under a mistaken diagnosis for the relief of symptoms produced by the diseased appendages. In but one case have I had an inflammatory attack follow this operation when there was no complicating

disease. In that case I made an incomplete dilatation without ether upon the dispensary table, in a young woman, married for 5 years and sterile. The inflammatory attack cleared up within a week, she soon conceived, and a month ago I delivered her safely of a large, healthy baby. She made a perfect and uncomplicated recovery. I should be exceedingly loath to discard the dilators from my armamentariun, and can only attribute serious accidents following their use to a wrong diagnosis or a faulty use of the instrument.

Intra-uterine Medication.—There is undoubtedly a limited field for the application of drugs to the uterine cavity. It should not be forgotten, however, that it is often only supplementary to other treatment. It is just as rational to expect results from local applications to the uterine mucous membrane, as from applications to the mucous membrane of the nose and throat. The fault here is much the same as in other minor operations —either a wrong diagnosis is made, or local applications are used to the exclusion of other and probably better methods of treatment, or they have been injudiciously and rudely applied. Certainly in chronic endometritis we may expect some good from them, especially after the application of the curette.

The Curette.—This instrument, in properly selected cases, is invaluable. In my own hands the dull curette has proven worthless, and I much prefer a sharp one. Of course, the instrument is capable of harm, but so is every other that is used in surgery. If even ordinary precautions are taken in selecting cases and manipulating the curette, no damage will follow its application. For affections of the endometrium following labor, or of a fungoid character, it is exceedingly useful; I know of nothing which will take its place. In removal of retained clots, etc., in the puerperium, the finger will be found to be more certain.

Operations on the Cervix.—The splitting up of the cervix for dysmenorrhœa and sterility has fallen into deserved disuse; all that can be accomplished in that direction can be done with the dilators.

Emmett's operation for the closure of lacerated crevix should meet much the same fate, at least in the vast majority of cases. The only excuse for the number of such operations which are being continually performed is a fear of subsequent cancer. A simple, uncomplicated cervical tear causes no more trouble or inconvenience to the patient than does a woman's ear which has been torn through by her earring. The ear would be repaired for cosmetic effects; the cervix is hidden from view, and that factor would not come into consideration. Most women have lacerations of the cervix of a more or less degree. If the lips are thickened, everted and eroded, they will need treatment. Oftentimes simple scarification, followed by the application of iodine and glycerin tampons, will reduce this condition and leave a clean, healthy tear—one which will remain so until the end of time. If the lips cannot be brought into a healthy condition, or if the uterus is subinvoluted and the endomentrium diseased, the case may resolve itself into an operative one; but even here a trial with electricity will often disappoint the surgeon. In my practice it is rare to see a a lacerated cervix which calls for surgical repair. Cases which come to me from other men, who have advised an operation, get well without it. Oftentimes the symptoms for which the operation was proposed were found to be due, not to the torn cervix at all, but to other troubles, principally constitutional.

It is the easiest thing in the world to relight a pelvic inflammation whilst repairing a cervix, and I have seen this result follow such practice only too often.

Taking it all in all, I decidedly approve of minor uterine surgery in the field to which it is applicable. but it must be borne in mind that this field is a limited one, and one which becomes more and more narrow as our diagnostic resources increase.—*Dr. J. M. Baldy, in the Medical News.*

GRAVES'S DISEASE RELIEVED BY REMOVAL OF SLOUGHING FIBROID.

Dr. Carl Wettergreen (*Centralb. f. Gynäk.*, February 28th, 1891; *Eira*, No. 11, 1890, p. 334) describes a case in which a woman, aged 47, suffered for over two years from a bleeding fibroid as well as from Graves's disease. The anæmia was extreme, apparently secondary to the hæmorrhage, and of the pernicious type. Therapeutic measures were tried for a time with no effect, except that the fibroid was delivered through the os and cut awuy with Siebold's scissors. It was bigger than a man's fist, submucous, and in parts gangrenous. After the operation the hæmorrhage ceased. The patient became much stronger; the protrusion of the eyeballs and the rapid pulse and palpitations abated to a marked degree.—*Brit. Med. Jour.*

THE NATURE OF HÆMATOSALPINX.

Dr. H. Walter (*Inaugural Thesis*, Giessen, 1890) strongly contests the now prevalent doctrine that hæmatosalpinx almost necessarily implies tubal gestation in a very early stage. He made a series of sections from two cases operated upon at Giessen, and examined them very carefully under the microscope. There was no distinct evidence of tubal pregnancy. He found structures which bore a certain resemblance to chorionic villi. He believed that they were shreds of structureless membrane with dark borders—mere fragments of fibrin in fact. Dr. Walter—in opposition to Orthmann—holds that tubal gestation cannot be diagnosed with certainty, unless at least decidua cells are present. He admits that, in his cases, the etiology was negative, yet by comparison the history and clinical course of the cases with the microscopic appearances of the sections of the tubes, he feels constrained to insist that the true nature of the disease was hæmorrhage into the tubal canal as a result of catarrhal inflamation of the tube. Hæmatosalpinx may involve grave results, but it does not follow even then that the original cause is tubal pregnancy.—*Brit. Med. Jour.*

OBSTETRICS.

PLACENTA PRÆVIA.

Braxton Hicks (*L' Union Med.*) lays down the following rules as regards treatment:

1. The diagnosis of placenta prævia once established you must terminate labor with the least possible delay.

2. When the operation has been commenced you must not leave your patient until it is completed.

3. When the cervix is completely dilated and the placenta is marginal, it is necessary to break the membranes, and see whether the head is pushed toward the neck during the pains.

4. If the head descends slowly, employ the forceps or perform version.

5. If the os is small and is more or less covered by the placenta, the latter should be cautiously detached around the whole circumference of the os. If there is no hæmorrhage, delay of one or two hours is permissible. If the os is not dilated and if you have no dilator at hand, you may dilate the cervix manually. If you think that the forceps may be easily applied, it is well to apply them. If not, it is necessary to do bi-polar version by the combined internal and external method. The cervix is thus tamponed by the legs or breech of the child. After this the treatment is the same as for any case of foot or breech presentation.

6. If the neck is small, and if you have neither forceps nor dilator, version must be done.

7. If during the manoeuvers here mentioned, a violent hæmorrhage occurs, version must be terminated by extraction of the fœtus.

8. When the fœtus is dead, or when labor comes on before the end of the seventh month, it is necessary to do version and leave the rest to nature.—*Archives of Gyn.*

UNIQUE CASE OF CÆSAREAN SECTION.

Dr. Chas. P. Noble reports in the *Amer. Jour. Obstet.* an exceptionally interesting case of cæsarian section.

On the 27th of April, 1890, he was called to see Mrs. J., the messenger stating that she was in labor, the water having come away. He found her a vigorous little woman, 27 years of age, fifty-five inches in height. She was in the ninth lunar month of her sixth pregnancy. The first four pregnancies ended in miscarriages. The fifth pregnancy was terminated by Cæsarean section, done by Dr. Howard A. Kelly, April 17th, 1888. During this labor Mrs. J. was successively in the hands of a midwife, a physician, and two physicians in consultation. The grave nature of the case was not recognized, and the attendants waited for two weeks for the cervix to dilate. At the end of two weeks Dr. Kelly saw her in consultation. The pelvis was found choked with inflammatory exudate, which made an absolute barrier to delivery *per vias naturales*. Cæsarean section was done, as affording the only hope to the patient for life. At the time she was profoundly prostrated, with a pulse of 142. A feeble, jaundiced infant was delivered, which lived a week. As a result of the conditions present at the time of the operation, the uterine wound became infected; circumscribed peritonitis, with adhesion of the womb to the abdominal wall, resulted, and later a breaking down in the line of union in the abdominal wall and uterus occurred, and thus a utero-abdominal fistula formed through which the uterine contents discharged externally. The cervix broke down, and half of it came away in a slough. The patient had a narrow escape, but recovered. The fistula never healed soundly; at times it would heal, only to break down at a

menstrual period to allow of the escape of some of the menstrual blood. The patient's general condition became good, and the pregnancy resulted which is the subject of this communication.

On examination Dr. Noble found that the membranes had ruptured, and that the waters were coming away through the ventral fistula, which was dilating under the influence of the feeble pains which were present. The cervix was scarcely at all dilated, and the os could be felt surrounded by cicatricial tissue left from inflammatory processes attending the preceding labor. It seemed plain, from the condition of the soft parts alone, that, were spontaneous labor possible, the child would be delivered through the ventral fistula and not through the vagina. The scar from the former Cæsarean section was found quite stretched out by the intra-abdominal pressure. The recti muscles were separated about one inch. The fistula was situated about midway between the pubes and the umbilicus. Projecting through the fistula a process of amnion was plainly seen. The child lay in the third position. The head was quite movable above the superior strait. The fœtal heart tones were easily heard, showing that the fœtus was alive, though it evidently was quite small and immature. The soft parts of the pelvic outlet were those of a nullipara. The cervix formed the centre of a mass of scar tissue. The lateral pelvic walls were easily palpated; but, owing to the scar tissue back of the cervix, it was difficult to reach the sacrum.

The pelvic measurements were as follows: A. S. S., twenty centimetres; Cr. I., twenty-five centimetres; D. B., fifteen centimetres. The conjugate diameter cannot be taken, owing to the fixation of the cervix.

The technical details of the operation were unique. Dr. Noble's index finger was inserted through the fistula into the uterus, and upon this as a guide he incised the uterus and abdominal wall above and below the fistula with the knife and scissors as far as the region of utero-abdominal adhesion. Sufficient room not being afforded, the peritoneal cavity was opened and the uterine incision prolonged upward; a leg of the fetus was now seized and the fetus turned and delivered. It was feeble and immature (thirty-third week), and lived only a few hours.

The placenta and membranes were found strongly adherent, and it required some time to remove them. In the meanwhile hæmorrhage was quite free and could not be controlled in the usual way, by the assistant grasping and compressing the cervical region, because of the intra-abdominal fixation. Dr. Noble quickly inverted the uterus through the operation wound, which enabled the assistant to grasp the lower uterine segment and control the bleeding, while he peeled off the secundines. The finger was now passed through the crevix to provide a vent for the lochia. The walls of the fistula were exsected, and the uterine incision closed by fifteen deep and seven superficial stitches. Some of the deep stitches passed through both uterine and abdominal walls, through the region of uterine adhesion. The fact accounts for the small number of superficial stitches used. The uterine wound was closed in twenty-nine minutes. The peritoneal cavity was now cleansed and the remaining sutures introduced. The patient was put to bed without shock. The convalescence was rapid and uninterrupted. Primary union of the operation wound was obtained; and, although a number of the buried uterine sutures have been discharged, the fistula has not re-formed.

Several features of this case make it of more than ordinary interest: The operation being unique, both in its indication and in its technique.

The case is of further interest from the fact that Mrs. J. is the second woman in Philadelphia to recover from the Cæsarean operation; curiously enough, the subject of the first Cæsarean section in this city also had two operations and likewise recovered from both, the operations being done in 1835 and 1837.

Practically, the most striking feature in the case is the difference in the convalescence after the two operations—the first done late, under desperate circumstances; the second done early, when the woman was in good condition. It is but another illustration of the folly and hazard of delay, and but another argument for early diagnosis and prompt operation.

PÆDIATRICS.

FŒTAL ENDOCARDITIS.

D. Porak (*Journal de Médecine de Paris*, No. 23) reports the case of a child, which became deeply jaundiced three days after birth. The next day it was, at intervals, very cyanotic; nothing abnormal heard over the heart. The fifth day there was decided embarrassment of respiration. Disseminated areas of dullness over both lungs, with moist rales. The child died the next day.

The autopsy showed large areas of red hepatization, the lung being non-crepitant and sinking in water. The right side of the heart showed a large and patent foramen ovale. The left auricle and ventricle are small, the ventricle especially contracted: its wall is of a yellowish-white color, and covered as if with tendinous cords, adherent to the wall. The mitral valve is represented by two or three small bulbar projections. The aortic valve has disappeared, its place being taken by a rigid, perforated membranous septum, with irregular thickening. The aortic orifice, as also the lumen of the aorta, is much smaller in diameter than usual. The wall of the ventricle is thickened.

Fœtal endocarditis is not as rare as one would suppose. Haranger reports three varieties: (1) With complete obliteration of the aortic orifice; (2) with disease, but not occlusion, of the aortic valve; (3) with isolated changes at the mitral. Collateral circulation is maintained either by the foramen ovale, ductus arteriosus, or by incomplete union of the ventricular septum.—*Cin. Lancet and Clinic.*

CROUPOUS PNEUMONIA TREATED BY DIGITALIS.

After several years' trial of the various methods of treatment which have been recommended for croupous pneumonia, Prof. Petresco (*Therap. Monat.*) has arrived at the conclusion that large doses of digitalis give the best results.

He administers in the course of 24 hours an infusion made from 4 to 8 g. of digitalis leaves. This daily quantity he continues during two to four days, according to the severity of the illness. In no instance were vomiting or other toxic effects occasioned by the medicine.

The temperature, as a rule, falls from one to three degrees after a single dose, and from five to six degrees after two or three doses. At the same time the pulse is reduced by from 40 to 60. This effect on the temperature and pulse continues for about ten or twelve days, during which time the lung, as a rule, returns to its normal condition.—*Cent. f. g. Therap.*

HYGIENE.

THE PARASITE OF QUARTAN AGUE.

In the *Zeitschrift für Hygiene,* vol. x, p. 137, appears the first of a series of papers by Camillo Golgi, demonstrating by means of photography the development of the parasite found in malarious fevers. This paper deals with the amœba malariæ febris quartanæ, the form found in the quartan type. In 1880 Laveran stated that these parasites are present in every case of malaria, and in no other condition, and that they are probably the cause of the disease. His observations have been confirmed by pathologists in all parts of the world, and at the present time the weight of proof seems to be in favor of his contention. In the above paper Golgi claims to have been the first to demonstrate that the different forms described as occurring in the blood are simply modifications of one form, and, further, that these metamorphoses follow each other according to a fixed law. This development takes place within, and leads to the destruction of the red blood corpuscles. At first the amœba-like parasite is small and non-pigmented; it increases in size at the expense of the substance of the blood corpuscles, becomes pigmented, and, after passing through a series of metamorphoses, finally ends in a process of segmentation. This process of segmentation takes place at the same time as, or short time before, the onset of the febrile paroxysm, and has for its object the formation of a new generation of the parasites. The pigment granules stored up in the body of the parasite take no part in this process of segmentation, and hence, on its completion, escape into the blood plasma, where they are seized upon by the white blood corpuscles and cells of the liver, spleen, etc. The new brood of parasites at once pass into fresh red blood corpuscles, and so commences anew the cycle of metamorphoses leading up to the next paroxysm of fever. The period of time which elapses between the entrance of the parasites into the red blood corpuscles and their segmentation is exactly three days, and hence arises the periodicity of the quartan type of malarial fever. During the first and second days the parasite passes through the various phases of its development within the blood corpuscles, on the third day segmentation takes place, the new brood is set free, and fever results; in other words, the period of apyrexia corresponds with the endoglobular growth of the parasite.

Golgi states that a knowledge of these developmental stages is of immense practical importance for the purpose of diagnosis, by which an almost mathematical degree of accuracy can be arrived at, and that it is no exaggeration to say that by the simple mi-

croscopic examination of a few preparations of blood the physician is in a position to tell when the last attack of fever occurred, to foretell the time of the next attack, and further to recognize what type of malarial fever he is dealing with. The simple quartan fever is explained by Golgi as resulting from the development in the blood of one set of the parasites, which ripen every three days, while the double and triple quartan fevers are caused by the development of two and three sets respectively, coming to maturity on consecutive days. This hypothesis, of course, cannot apply to the tertian type of of malarious fever, since in this the febrile paroxysms follow each other with an interval of only one day of apyrexia intervening, instead of two days as in the case of the quartan type. Golgi is of the opinion that he has brought forward satisfactory evidence to show that tertian ague depends on the presence in the blood of a distinct variety of the malaria parasite, which passes through its developmental phases in two days instead of in three. In regard to classification, Golgi holds that the various clinical types of intermittent fever are caused by varieties of one and the same parasitic species, and that this belongs to the genius amœba. The twelve photographs which illustrate his first paper deal with the development of the parasite of quartan fever, and show, surrounded by normal red blood corpuscles, its successive metamorphoses. The photographs, which are very fine, were taken by means of Zeiss's microphotographic apparatus.—*Brit. Med. Jour.*

MEDICAL CHEMISTRY.

THE MERCURIC TEST FOR MYDRIATIC BASES.

In the *Pharmaceutical Journal* of March 8, 1884, A. W. Gerrard described a group test distinguishing atropine, hyoscyamina, daturine, and homatropine from other alkaloids. The test pointed out that the above pure bases, when gently warmed with a 5 per cent. solution of mercuric chloride in spirit and water, gave a red precipitate of mercuric oxide. Since its publication the test has been confirmed by Professor Flückiger, Dr. Schweissinger, and others. With the publication of the recent "Additions" to the British Pharmacopœia the test has appeared officially in that work in connection with hydrobromate of homatropine. The official test differs from Gerrard's by the use of a 2 per cent. solution of mercuric chloride instead of a 5 per cent. solution a difference of little moment. Quite recently the test has been criticised by P. W. and A. H. Squire in their "Supplement to the Companion to the B. P.," especially as regards hyoscyamine. These authors remark that treated in the same way as hydrobromate of homatropine, "hyoscyamine salts give the yellow precipitate which, however, does not turn red." Having but little doubt of the correctness of my former work, it was yet thought desirable to repeat my experiments. This has been done, and the results are fully confirmatory of former statements.

As the method of applying the test requires care it is as well to repeat it here. Place about $\frac{1}{10}$ grain of pure hyoscyamine, extracted from a salt by ammonia and chloroform, upon a watch glass or in a test tube, carefully add 20 minims of 2 per cent. solution of mercuric chloride in proof spirit, watching the change. At first the hyoscyamine becomes pale yellow, then darkens a little, finally heating a well marked red precipitate is formed. How the Messrs. Squire failed to obtain a like result it is difficult to understand, but either the testing or the hyoscyamine must have been at fault.

As regards hyoscine, Messrs. Squire state that it yields no mercuric oxide under the above test. This Mr. Gerrard has confirmed, so it is a character which enables us easily to distinguish hyoscine from other mydriatic bases.—*Ph. Jr. Trs.*

SIMPLE METHOD OF DIFFERENTING BUTTER AND OLEOMARGARIN.

A. R. T., St. Louis.—Please give (if there is any) a simple and ready method of telling artificial butter, hog butter, somebody has called it—from the genuine article.

As stated in a recent number of this journal, probably the easiest test, of any reliability at least, is the alcoholic solution of silver nitrate. Dissolve 25 parts of the silver nitrate in 100 parts of alcohol of 95°. Put some of this solution in a test-tube, and melt and add a portion of the material to be tested. Agitate for a few moments, and let stand. Pure butter retains its natural color, while the margarine will become a dirty brick red, the color of a mixed sample depending upon the quantity of the adulterant present therein. The test is said to be sufficiently delicate to detect 5 per cent. of margarin, while with 10 per cent. the color reaction is very strong.

Bodairy has devised a process by which the percentage of oleomargarin in adulterated

butter may be rapidly determined with an approach to exactness. It is as follows: Into a graduated test-tube of large size pour 15 ccm. of toluol. To this add 15 ccm. of the butter to be analyzed, after having melted and strained it, pour on top of the butter 50 ccm. of alcohol of 97°, shake, and place the whole in a water-bath heated 50° C. The liquid remains clear, or nearly so, if the butter be pure, while if margarin be present it first becomes turbid, and later separates into two layers, of which the upper contains the margarin. The following gives the approximate percentages of margarin ascertained by the volume of the layer:

11 ccm. of layer	10 per cent. margarin.
14 ccm. of layer	20 per cent. margarin.
19 ccm. of layer	50 per cent. margarin.
29 ccm. of layer	75 per cent. margarin.

—*Nat. Drug.*

NEWS AND MISCELLANY.

JOURNAL OF COMPARATIVE NEUROLOGY.

This Journal is a quarterly, of about 100 pages, and edited by Dr. C. L. Herick.

THE MEDICAL SOCIETY OF FRANKLIN COUNTY, PA.

The Medical Society of Franklin county, will hold its annual session July 21st, at Chambersburg. Dr. John Montgomery will deliver the address of welcome, and papers will be read by Dr. D. F. Unger, Dr. Geo. F. Hall, and Dr. I. F. Snively.

VIS MEDICATRIX.

This is the title of a new bi-monthly Journal of Medicine, human and comparative, under the editorship of Woods Hutchinson, A. M., M. D.. who has as associates L. H. Pammel, B. Agr., and S. Stewart, M. D., D. V. M. The Journal is the organ of the Iowa State Medical Society.

NEW APPOINTMENTS AT THE PHILADELPHIA POLYCLINIC.

Dr. A. R. Wharton has been elected Lecturer on Surgical Diseases of Children. Dr. Chas. P. Noble has been elected Lecturer on Gynecology; Dr. Jas. K. Young, Lecturer on Orthopædic Surgery; Dr. G. Betton Massey, Lecturer on Gynæcological Electrotherapeutics, and Dr. Lewis H. Adler, Lecturer on Diseases of the Rectum.

OHIO STATE MEDICAL SOCIETY.

The Ohio State Medical Society held its 42nd annual session at Sandusky, June 18, 19 and 20, 1891. Dr. W. J. Conklin, of Dayton presided, and Dr. G. A. Collamore, of Toledo was Secretary. More physicians were present than attended the meeting last year.

The officers for the next year are: President, Dr. G. A. Collamore, Toledo; First Vice-President, Dr. X. C. Scott, Cleveland; Second Vice-President, Dr. A. G. Gaume, Sandusky; Third Vice-President, Dr. A. R. Baker, Cleveland; Fourth Vice-President, Dr. F. D. Bain, Kenton; Secretary, Dr. T. Fitzpatrick, Cincinnati; Assistant Secretary, August Rhu, Marion; Treasurer and Librarian, Dr. T. W. Jones, Columbus. The following members of Committees were appointed for five years: Finance, H. J. Herrick, Cleveland; Legislation, D. J. Snyder, Columbus; Ethics, S. S. Thorn, Toledo; Publication, E. S. McKee, Cincinnati; Admissions, H. F. Hose, Cleveland.

Cincinnati was selected as the place of the next meeting to be held in May, 1892.

The members were entertained by an excursion to Cedar Point where the President's address was delivered and a concert given, followed by a banquet. An excursion to Put-In-Bay, Kelley's Island, Lakeside and Middle Bass was enjoyed on Friday afternoon and evening after the close of the meeting. The President's address was on Moliere and the Doctors, and consisted principally of historical material concerning Moliere and his numerous sayings concerning the medical profession.

The Committee appointed to secure the passage of a law for the protection of physicians, reported that not liking the complexion of the present Legislature, they had not essayed anything.

The subject of Contract Railroad Surgeons, referred from the American Medical Association, was brought up and referred to a committee of five. The resolution making the members of auxiliary societies, that is county and district medical societies, members of the State Medical Society, was passed after some discussion. Indiana and other States have greatly improved their membership in this way. The business of the society is to be done by delegates and all who are now members will not be affected by this change, i. e. deprived of their right of suffrage.

Clinical Lecture.

TUBERCULAR PERITONITIS — PLEURO-PNEUMONIA—OR PNEUMONIA WITH AN EXCESSIVE AMOUNT OF DRY PLEURISY.

BY L. EMMETT HOLT, M. D.,

PROFESSOR OF DISEASES OF CHILDREN AT THE NEW YORK POLYCLINIC, ETC.

Gentlemen:—This little patient whom I present to you to-day illustrates a pathological condition which is of some interest to us from a diagnostic standpoint. Her mother brings her to the clinic for diagnosis and treatment, but as she gives us no history, we are compelled to fall back on general clinical experience to solve this problem of diagnosis.

This little girl is, the mother states, four years of age, and the chief symptom that she presents is an enlargement of the abdomen. The only way by which we can reach a probable diagnosis in this case is by a process of exclusion. What then is the most frequent cause of abdominal enlargement in young children? One gentleman says rickets. Yes, we do find in rachitic children an enlargement of the abdomen, but the bones, muscles and ligaments are also affected in this disease. In this case, all these symptoms are wanting. Furthermore, this child is four years of age, and we generally see this rachitic enlargement of the abdomen between the first and second years. There is here no knock-knee, no bow-legs, or other pathological sign of rickets.

Now, what are the other causes we must look for to explain this trouble?

Another gentleman says it may be ascites or heart disease. We do not generally get ascites in Bright's disease, without dropsy of the feet. When there is an interference to the return circulation from valvular disease of the heart, we get swelling of the feet as a first symptom. That condition is not present here. The fact that dropsy begins in the abdomen and not in the feet leads us at once away from the kidney and heart as causative factors in this condition.

We would then suspect in this child abdominal rather than thoracic disease, and the liver and peritoneum would be the first organ to be scrutinized. A diagnosis is reached in any obscure case like this one only by examining carefully every organ. I have examined the patient's lungs and find nothing abnormal. Respiration is somewhat interfered with by the compression of the lungs upwards, which is due to the abdominal distention. The enlargement of the abdomen, you will observe, is very nearly symmetrical. The circumference at the umbilicus is 23¼ inches. By percussion from above downwards on the right side in the axillary line, we begin to get dullness at an inch below the level of the nipple. This dullness is probably hepatic in character, as it disappears at the free border of the ribs, and we get the normal tympanitic resonance of the intestines until a point on a level with the crest of the ilium is reached; below this point there is dullness again.

On the left side of the axillary line we begin to get dullness about two inches below the mammary line, and from this point down into the iliac fossa, there is continuous, uniform dullness, almost flatness. In the median line, the dullness begins at the umbilicus and extends to the symphysis. In the erect position then, we have an area of abdominal dullness occupying the left portion of the abdominal cavity and extending obliquely from the umbilicus to the spine of the ilium. In the recumbent position we find the area of dullness is somewhat altered. There is more resonance in the median line, in fact, all about the umbilical region, and a little more dullness in the right loin than when the patient was standing. The sense of fluctuation is very distinct in the lower portion of the abdominal cavity.

As the patient stands up, you notice an enlargement of the left abdomen, and by the sense of touch we get a feeling that somewhat resembles hernia. The assistant who sent the child to the clinic stated that he introduced a needle into the abdomen and withdrew serum. Apparently, then there is some fluid in the peritoneal cavity which has dilated the process of peritoneum away down into the abdomen and has produced here a reducible hydrocele. This is almost a demonstration of the fact that there is an accumulation of fluid in the peritoneal cavity, and there can be no doubt then that we have here an accumulation of fluid in the peritoneum.

The question now arises whether this is primary, or whether it is secondary, to some other pathological condition. It is impossible from the amount of abdominal distention present to satisfactorily palpate either the liver or the spleen.

Cirrhosis of the liver, we know, is a most frequent cause of ascites in adults. It is, however, an exceedingly rare condition in children, and has been scarcely ever observed at the age of four years. This swelling of the abdomen beginning on the left side, suggests the possibility of an ovarian cyst. This again is an extremely rare condition in childhood, and furthermore, the enlargement has been too rapid to admit of such an explanation. The presence of fluid in the region before you shows that the greater part of the distention at present is due to the accumulation of fluid in the peritoneum.

Malignant disease of the kidney as a primary condition, and peritonitis as a secondary one is a possible explanation of the symptoms here present. The urine of this patient has been examined several times and has shown neither pus, blood, nor albumen. In fact there has been nothing found that would indicate any serious renal affection. The child's condition is so good that we would hardly suspect malignant disease. The enlargement being so much greater upon one side than upon the other is about the only thing which would suggest some renal complication in this case.

Hydronephrosis is another condition which might be suspected here. There is no history, however, of renal colic and the bulging of the tumor is not so much in the lumbar region as is usually found in such cases.

We fall back then upon the primary disease of the peritoneum as, under the circumstances, perhaps, the most likely diagnosis. Tubercular peritonitis is a not uncommon disease in children of this age. It exists in two distinct forms, one the dry form in which there are plastic products binding down the intestines, together with a thickening of the omentum and tubercular deposits everywhere; the other form is associated with abdominal dropsy which may be general over the whole abdominal cavity, or may be shut in by various old adhesions as to be sacculated. This seems to be, under all circumstances, the most likely diagnosis in our patient's case this morning.

It is to be borne in mind, however, that several of the most characteristic symptoms of tubercular peritonitis are wanting. The first one is pain, second tenderness, third the presence of nodules in the abdominal cavity, and fourth the absence of temperature. It may be thought that in the absence of these signs we are hardly justifiable in making a diagnosis of tubercular peritonitis. It is to be borne in mind, however, that this disease often runs a very latent course and in many cases, the only symptom present is abdominal dropsy. The patient's temperature has been taken on several occasions, and has not been found elevated at any time. Furthermore, the other organs are free from any evidence of tubercular disease. If this were present, it would add much to the strength of our supposition.

In this connection, I wish to recall to your minds another patient with abdominal distention who was shown in the clinic about two months ago. The patient was a girl of about the same age as the child just before us, and many points in the history corresponded closely to those of this little girl. In her case, however, there was found marked tenderness over the greater part of the abdomen, five or six irregular nodules, from one to one and a half inches in diameter, chiefly in the region of the umbilicus and consolidation at the apex of the left lung. In this case the diagnosis of tubercular peritonitis was made with almost absolute certainty. The child, I have since learned, has died at home.

Most of these cases of tubercular peritonitis run a chronic, insiduous course, and unless operated upon, terminate fatally. The effects of a simple incision in those cases of the dropsical variety is sometimes marvelous and quite a considerable number of patients are now on record as having been completely cured by this means. In most of these cases the abdomen was opened under the impression that some other disease existed, and upon finding the peritoneum studded with miliary tubercles, the abdomen was simply washed out and the wound closed.

The improvement which followed this procedure was a great surprise to the physician. Laparotomy in cases of tubercular peritonitis is now considered a justifiable operation, and Dr. McCosh, of this City, recently showed at one of the societies a patient upon whom he had operated nearly a year before who at the time of operation had active pulmonary symptoms, with the physical signs of a cavity in the right lung. The abdominal symptoms entirely disappeared after the operation and the pulmonary symptoms had remained quiescent. I do not know of any successful operations of this nature as yet upon children so young as our little patient, but under the circumstances, it seems to me that an exploratory incision is justifiable and I shall recommend that the child be admitted into the hospital with this end in view.

PLEURO-PNEUMONIA, OR PNEUMONIA WITH AN EXCESSIVE AMOUNT OF DRY PLEURISY.

These specimens which I now pass around for your inspection were taken yesterday from the body of a female child eleven months old, who came into the Hospital with acute pulmonary symptoms two days before death. On admission, the temperature was 103° F. and there was great prostration, severe dyspnœa and moderate cyanosis. The respirations were frequent, up to 80 per minute, and the pulse was so rapid that it could hardly be counted. The physical signs presented were flatness over the whole left chest, with bronchial breathing, absence of vocal frenitus and voice, with friction sounds heard everywhere.

The heart was not apparently displaced, although the apex beat could not be certainly located. A hypodermic needle was inserted under the supposition that there might be effusion into the chest, but only a few drops of serum were obtained. The child sunk gradually and died of exhaustion about 24 hours after admission into the Hospital.

At the autopsy a condition which I show you here was discovered. The left lung was completely enveloped in a thick layer of greenish-yellow fibrin, being in many places a quarter of an inch thick. This could be scraped off from the parietal pleura by the handful. Loose adhesions existed between the two layers of the pleura, and in the meshes of this fibrin were here and there a few drops of serum. One section of the lung, the lower lobe was found consolidated, with a typical broncho-pneumonia and the posterior part of the upper lobe. The pleurisy, however, enveloped the whole lung quite up to the pericardium and also to the diaphragm. The opposite lung was normal, except for some patches of congestion. In the central portion of the lower lobe of the left lung were found two or three small gangrenous areas. These were grayish in color, sharply circumscribed and soft upon the surface. There was no gangrenous odor.

The heart shows the left ventricle to be normal, the left auricle is filled with a decolorized thrombus, and the right ventricle distended with a frequently organized thrombus, which extends a considerable distance into the pulmonary artery, as large as a small pipe stem. It also extends through the tricuspid orifice. We have in this condition of the heart, probably, an explanation of these areas of gangrene. They are almost certainly due to thrombus of some of the smaller branches of the pulmonary artery in the lung. That is what I frequently found on dissection in similar cases. The other organs were essentially normal.

The cases of pneumonia, with an excessive amount of dry pleurisy are exceedingly puzzling ones at the bed side. The physical signs are such as would lead usually to the diagnosis of an effusion of pus or serum into the pleural cavity. Not infrequently a drop or two of pus may be found with an exploring needle, and even incision may be made under the supposition that we have to do with an empyema. At the operation or the autopsy, the true condition of things is revealed. The existence of friction sounds all over the chest and the absence of displacement of the heart, are the symptoms which lead us to doubt the diagnosis of effusion. So far as percussion and the other auscultatory signs are concerned, they are practically identical with those found in effusion. This excussive production of fibrin not infrequently breaks down and forms an ordinary empyema. So if the patient had lived a few days longer we might have found plenty of pus at our exploratory puncture.

COMMUNICATIONS.

INVERSION OF THE UTERUS.

BY J. M. BALDY, M. D.

PROFESSOR OF GYNÆCOLOGY, PHILADELPHIA POLYCLINIC AND COLLEGE FOR GRADUATES IN MEDICINE.

From time to time cases of inversion of the uterus are reported, but they are not of

such common occurrence as to make the report of additional ones superfluous. It is notorious how difficult it is to cure this disease and how many devices have been invented for this purpose; in spite of all efforts it still remains one of the most unsatisfactory of gynæcological affections to handle successfully.

In 1888 I was asked by Drs. Urich of Annville, and Gloninger of Lebanon, Penna. to see a woman who gave me the following history. She was 33 years old and had borne one child eight years before. The labor was somewhat tedious and forceps were applied. During her lying-in she noticed that something protruded from the vulvar orifice, but on inquiry was told by her doctor that all women were so and that it would come all right. His predictions, however, proved unavailing and as time went by the mass protruded more and more. She bled frequently and profusely; the flow was always very painful. The mass was very tender and could only be pushed back, with great difficulty. An examination showed a condition of complete inversion, complicated by complete prolapse of the uterus and its appendages. The ovaries, situated at the lowest point of the mass, were large and extremely tender; in attempting replacement it was almost impossible to avoid pressure on them. Micturition and defecation could only be accomplished by reducing the whole mass within the vagina. The woman's husband had long since deserted her on account of her condition. She herself was mentally unbalanced and altogether a pitiable object. As I was on the eve of departure from the country I turned her over to another physician who admitted her to the Hospital. One year later while on a visit to the country I was asked once more to see the patient. Subsequently on inquiry from her physician I obtained the following result of his treatment. For one week after being admitted to the Hospital she had been daily placed in the knee chest position, the whole mass had been returned into the vagina and a tampon placed to retain it in position. At the end of this time the uterus was found to have returned to its normal position. The inversion had been replaced as it were spontaneously. At this point of the treatment the woman demanded her discharge, refusing any further aid and returned home to the country. When I saw her a year afterward, there was the old condition of prolapse and a tendency of the inversion to return. I performed the Emmett operation on the anterior wall of the vagina taking in as much of the relaxed tissue as possible, and closed the perineum after the method of Emmett. Within a few months the whole mass had again prolapsed and I was asked to try once more. This time I removed the ovaries, which I found as large as walnuts, and badly diseased. In this I had a triple object: the relief of her pain, which was severe; the establishment of the menopause and the consequent prevention of the monthly congestions, each one of which caused an increase in the weight of the pelvic organs, and made the parts prolapse more and more; the drawing up of the prolapsed organs and their support from above. In placing the ligatures, care was observed to take in all the slack possible of the broad ligaments. The ligature perforated the broad ligament below the round ligament and included this organ in its grasp, in this way giving additional support to the drawn up uterus. The uterus was stitched to the abdominal walls. Like the former operations, this one proved a failure and soon the prolapse was as bad as ever. In the course of time I had an innumerable number of letters from both herself and her doctors, asking for another attempt at relief. After all this treatment she was not only suffering from the prolapse, but the uterus had again inverted. I agreed to make one more effort to cure her, provided she would come to the city and put herself unreservedly under my care. At the same time I told them that I should have to remove the uterus. I heard nothing more of the patient until within a month, when I discovered that she had gone to the almshouse in Lebanon County, where her uterus had been removed per vaginum. If I remember correctly I was told that there was still some prolapse of the vaginal walls which will probably require a plastic operation for its cure. After some eleven years of constant suffering, this poor woman deserted by her husband and family through the neglect and ignorance of her physician during her confinement, has been forced to go to the almshouse in a state of insanity.

This case presents many points of interest. The ease with which the inverted uterus was replaced is not altogether unique. Robert Barnes in the second edition of his *Diseases of Women*, and R. P. Harris in the *American Journal of Medical Sciences*, January, 1880, makes mention of spontaneous reduction of inverted uteri. Dr. Charles C. Lee (*American Journal of Obstetrics*, 1888) has reported two cases, in which reduction occurred after

a few weeks application of the vaginal tampon. The case under discussion returned to its normal position after even a shorter course of treatment than did those of Lee.

The failure to keep the uterus in its normal condition and cure the prolapse was probably due to a combination of circumstances. The woman was mentally unbalanced. She would demand an operation and just as soon as it was performed she would refuse to allow any attempt to hold what was gained by supplementary proceedures. When, however, she found that one operation had failed she would demand another and so on to the end. Could the plastic operations have been supplemented by the laparotomy, a success might have resulted; but the good effects of one operation were ruined before the other could be obtained.

One point of scientific interest I have as yet failed to mention. While the uterus was inverted, the uterine openings of the Fallopian tubes were in plain sight. I had several opportunities of observing the patient during the process of menstruation. The dark *menstrual blood all came from the tubes.* The mucous membrane of the uterus remained in the usual condition, but the flow from the tubal openings was free and had all the characteristics of the normal menstrual blood. This case would seem then to go a great way towards sustaining Tait's theory of menstruation. The fact that there was no exudation from the endometrium is not so surprising, considering how long it had been exposed to foreign influences, but the free tubal hæmorrhage is significant. I have seen cases of inversion in which the bleeding occurred all the more profusely from the endometrium, but the inversion in these cases has been of more recent occurrence and there was in one case polypoid growths at the fundus.

My experience with this disease would prevent me from ever using any of the forcible methods of replacement which are at present and have in the past been in use, and which are recommended in all the text books. If failure to reduce an inverted uterus follow firm and persistent use of the vaginal tampon, the only rational procedure is vaginal hysterectomy. Occasionally, cases are reduced by some of the many methods recommended, but most often they fail. Of these proceedures the one proposed by Aveling is the most scientific and most successful. This consists of continuous elastic pressure in the line of the axis of the pelvis. A special instrument is necessary and the operation extends at times for days. Following manual attempts at reduction, I have seen a peritonitis set up, as proven subsequently, by a laparotomy, which caused adhesion of every thing situated in the pelvis; tubes, ovaries, intestines and omentum. Even then the inversion was not reduced. I have seen the abdomen opened, a stout cord passed through the fundus into the vagina, a button attached to the vaginal end and traction made upon the cord. As an aid to this the cervix was dilated from above with dilators and at the same time efforts were made through the vagina, with the hand, to assist in the reduction, all resulting in failure. In fact I have seen a button tear through the uterus while traction was being made on the cord and the patient die in spite of the fact that the inverted fundus with the hole in it was amputated. The amount of manipulation before the amputation was too much for the woman's already reduced strength.

I consider all these methods distinctly illogical and dangerous and believe they should all be condemned in favor of the quick, safe and sure method of vaginal hysterectomy, provided that the vaginal tampon has failed after having been used as above indicated.

REPORT OF CASES.*

EMPYEMA IN A CHILD FOUR YEARS OLD—PIN IN LARYNX OF CHILD REMOVED BY ENDO-LARYNGEAL METHOD—A NON-MALIGNANT GROWTH ON VOCAL CORD SUCCESSFULLY REMOVED—DIPHTHERITIC CROUP AT THE AGE OF SIXTY YEARS.

BY F. E. WAXHAM, M. D., CHICAGO.

PROFESSOR OF DISEASES OF CHILDREN, LARYNGOLOGY AND RHINOLOGY COLLEGE OF PHYSICIANS AND SURGEONS OF CHICAGO; PROFESSOR OF LARYNGOLOGY AND RHINOLOGY POST-GRADUATE MEDICAL SCHOOL OF CHICAGO.

The first case, that of empyema in a child, is especially interesting on account of the many complications and the remarkable vitality of the patient. Among the most common causes of empyema in children are pleurisy, pneumonia and diphtheria. In this case all these causes combined to produce the disease together with very unfavorable hygienic surroundings. On May 1st of last year I was called through the courtesy of Dr. Meyeronitz to perform intubation upon a boy between three and four years of age,

*Read before the Chicago Medical Society, July 6, 1891.

and learned that he had been ill with pharyngeal diphtheria for a number of days. The child was much prostrated, the disease had invaded the larynx, respiration was difficult indeed, and death seemed inevitable. The operation was performed giving immediate relief to the urgent symptoms. After six days the boy was able to breathe without the tube and seemed in a fair way to recover.

Four weeks later I was again called and found the patient with a dangerous attack of pleuro-pneumonia. The symptoms were severe and positive. The child had not completely recovered from the effects of the diphtheria when he came down with the pneumonia. Although the dangerous symptoms subsided in the course of ten days, yet some fever continued, the cough remained troublesome, together with some dyspnœa and dullness over a considerable portion of right lung.

Upon aspirating with a hypodermic needle pus was found in the pleural cavity.

June the 29th with the assistance of Dr. Meyeronitz, a free incision was made in the axillary line in the sixth interspace, and a large amount of pus evacuated. A double drainage tube was inserted and the pleural cavity thoroughly washed with a warm saturated solution of boracic acid and antiseptic dressings applied. The amount of pus gradually diminished, but did not entirely cease, and upon careful search for the cause of the persistent discharge it was found in the presence of a necrosed rib. Although the child was greatly emaciated, there was still a fair amount of vitality and it was determined to excise the rib.

August 7th, again assisted by Dr. Meyeronitz, an anæsthetic was administered and several inches of necrosed rib removed, and antiseptic dressings applied. The child now made a speedy recovery and since has remained perfectly well.

Case II.—*Pin in the Larynx.* This case is interesting on account of the peculiar position of the pin. The case I believe to be unique, having never heard or read of a similar case.

January 1st, Dr. M. W. Bacon, of Englewood, referred this patient to me, and the following history was elicited: "Twenty-four hours previously while holding a pin in the mouth it slipped down his throat and after coughing violently for a moment a sharp pain was felt which was greatly intensified upon swallowing. The pin had fallen into the larynx head first, and when the spasmodic cough occurred, the point which was very sharp was driven upward into the epiglottis. Dr. Bacon being consulted, wisely advised the swallowing of a crust of bread; as this was done the head of the pin striking against the walls of the larynx the point was more deeply forced into the epiglottis, as the latter was pressed down by the bolus during the act of swallowing, and the pin was thus insured against accidentally dropping into the trachea.

The symptoms indicating the presence of the pin in the larynx, were a more or less frequent cough, constant pricking pain in the throat and difficult and very painful deglutition. Although but ten years old, the boy was intelligent and tractable and permitted a careful laryngoscopic examination. The pin was plainly seen with the head directed downward into the glottis, and the point firmly implanted in the tip of the epiglottis. After anæsthetizing the throat with a ten per cent. solution of cocaine, a careful attempt was made at removal. A modified Cusco's forceps was employed and guided by the mirror introduced, and the pin firmly grasped and removed at the expense of some slight injury to the epiglottis as the point of the pin tore through it. For two or three days there remained some pain, especially upon swallowing, but this soon subsided."

Case III.—*Non-malignant Growth on Vocal Cord.*—D. H., a vocal music teacher, consulted me January 22d, on account of impairment of the voice. There was not complete aphonia, and yet the voice had gradually become hoarse and husky, and now completely interfered with his occupation. Upon careful laryngoscopic examination a small reddish growth half the size of a buckshot, and with a broad base, was seen upon the right vocal cord. This growth, though not large, prevented the close approximation and normal vibration of the vocal cords. Our authorities do not generally recommend the removal of non-malignant growths unless their position or size is such as to endanger life by obstruction to respiration. Indeed some state positively that the only indication for their removal is rapid growth and dyspnœa, and strongly advise guarded instruments instead of cutting forceps when removed on account of the great danger of injury to the vocal cords and subsequent inflammation and swelling of the mucous membrane of the larynx. In this case, on account of the great hardship resulting from the loss of occupation, it seemed that we were justified in a careful attempt at removal. For reason of the small size of the growth and broad attachment, the cutting

forceps was the only instrument suitable for the removal. The throat and larynx were thoroughly anæsthetized with cocaine, the instrument warmed and passed down into the larynx guided by the mirror. He was now directed to take a deep breath and produce the prolonged sound of A in a high pitch, and as the vocal cords approximated, the growth was seized with forceps and removed. The growth upon removal was found to be a small myxo-fibroma. For a few days following the operation there was slight congestion of the right vocal band, but this soon passed away after a few applications of chloride of zinc (gr. 111 to ℥1). Three months later upon examination of the larynx both vocal cords were perfectly natural. There was not the slightest evidence of return of the growth, the patient had resumed his occupation, and the voice was clear and perfect.

Case IV.—*Diphtheritic Croup at the age of sixty years.* On April 15th, I was called, through the courtesy of Dr. A. E. Palmer, of Morris, Illinois, to see Mrs. M. B., a lady of great culture and refinement. On arriving at 11 A. M., the patient was found breathing with great difficulty; the pulse was small and very weak, and the extremities were becoming cold. Intelligence, however, was unimpaired, and she complained of a great sense of suffocation. Dr. Palmer has very kindly given me the following history;

"Mrs. B., aged 60, never had any serious illness. Had chronic pharyngitis, and at about the age of 40 had several attacks of spasmodic croup. Two weeks before last illness, she visited Braidwood, and as there had not been a case of diphtheria in Morris for many months it was thought that she may have contracted the disease there. Friday, April 10, 1891, was slightly indisposed, also April 11th. Sunday, April 12th, was very much better and unusually vivacious. Monday morning at 2, was called on account of the difficulty of breathing and found false membrane, covering a large portion of the fauces. Tuesday the membrane was less, but the breathing more difficult. Wednesday, April 15th, Dr. Palmer summoned me to his assistance to perform intubation, and the symptoms had become so urgent that there was but little time for delay. An adult tube was armed with thread and attached to the introducer. The patient was placed in a sitting position in bed and was well supported. The gag was placed between the teeth and the tube quickly introduced into the larynx. As this was done respiration was at once arrested, membrane having been pushed down in front of the tube. After waiting a moment the tube was quickly withdrawn and the expulsive cough which followed expelled a large membrane exudate which you observe is a perfect cast of the whole trachea. Respiration now became perfectly normal, the pulse improved, the color returned, and the patient expressed herself as comfortable. As there was not the slightest impediment to respiration it was decided not to re-introduce the tube."

In regard to the subsequent history, Dr. Palmer writes as follows: "There was entire relief until Thursday noon, when symptoms of pulmonary obstruction supervened and steadily increased until death occurred very easily and quietly at 4 P. M., Friday, April 17, 1891. There has not been a case of diphtheria in Morris since the death of Mrs. B."

A CASE OF GASTRALGIA CURED BY TRACHELORRAPHY.

BY ALICE McLEAN ROSS, M. D.,

RESIDENT PHYSICIAN IN THE WOMAN'S HOSPITAL AND FOUNDLING'S HOME, OF DETROIT, MICH.

May X—Delivered upon the evening of Feb. 22, of a female child weighing eight pounds. The perinæum was slightly lacerated, one silver wire suture was inserted and good union resulted. The lying-in period was marked only by the occurrence of cramp-like pains in the lower part of the abdomen, with a rise of temperature to 101° F. on the fifth day, which all subsided under the application of heat and the administration of analgesics. The child developed an eroding ulcer of the soft palate with syphilitic cacluxia, and was put upon grey powder, gr. j morning and evening.

The ulcer was touched daily with a mitigated stick of silver nitrate, and the little patient is doing fairly well. There were no active manifestations of syphilis in the mother, and never had been as far as could be learned from the history and a careful physical examination, but nevertheless, I believe that in these cases there is a mild specific poisoning which will show itself sooner or later. I always allow these mothers to nurse their children, never fearing infection of the nipple from any open lesion in the mouth. I put the mother upon small doses of corrosive sublimates, and all went well until the fifteenth day, when she was attacked with terrific gastralgia. The pains were intense, lancinating and she

said, much harder to bear than those of labor. They subsided in an hour, under large doses of morphine, and that same evening she had another paroxysm which terminated with vomiting. These continued, occurring sometimes twice, sometimes four times in the twenty-four hours. At first they generally terminated with vomiting, later they simply died away under the influence of anodynes, and hot applications. The patient's life was a misery to her, for besides the actual agony, she was constantly dreading the onset of pain. I increased the dose of mercury to the point of tolerance, but all to no purpose. Much attention was paid to diet, and the food was well masticated, but it was found that the paroxysms came on as often after eating lightly, or not at all as after a hearty meal. Pepsin and dilute hydrochloric acid were given regularly, but digestion seemed good. Bismuth sub-nitrate in thirty grain doses was tried, also the bromides, but all to no avail. The attacks continued with the same severity, but a little less frequently, and the only relief was chloral, which was found to act better than morphia, together with hot applications and blisters over the stomach. As a matter of duty, I made a thorough examination of the pelvic organs and found a small laceration of the cervix upon the left side, extending about one-half inch into the muscular tissue. It was somewhat tender to the touch, and I resolved that if all else failed, I should advise operation. After much opposition on the part of the patient trachelorraphy was performed by Dr. Walter J. Cree, Consulting Physician to the Woman's Hospital. Two silver wire sutures were inserted, and all medication was suspended, and the result was most gratifying. The patient did not have a single return of the trouble, while the stitches were in place. They were removed upon the tenth day, and union was perfect. On the eleventh day, there was a mild return of pain which was probably caused by a little irritation where the wire had been. It is now a little over a month since she has been allowed to get out of bed. She is nursing her babe, walks up and down two flights of stairs many times a day, and has only had two very mild attacks of pain, after overdoing. She is in splendid condition, and thankful that she was compelled to submit to the operation. The babe has not borne mercury very well, and I have since put the mother again on small doses of bichloride, in the hope of assisting in its medication through the milk. No bad effects have been noticable, so it could not have been the mercury, which was suspended after the operation, that caused the trouble, in the first instance.

This is one of the happy results of this operation, and illustrates the advisability of examination of uterus and appendages in all nervous troubles in women, and also of operation before the nervous system has become such a wreck that nothing short of a miracle could effect a cure.

ON THE ANTI-MALARIAL PROPERTIES OF PAMBOTANO (CALLIANDRA HOUSTONI).*

BY A. E. ROUSSEL, M. D.,

DEMONSTRATOR OF PHYSICAL DIAGNOSIS IN THE MEDICO CHIRURGICAL COLLEGE—PHYSICIAN TO THE HOWARD HOSPITAL—TO THE SOUTHWESTERN HOSPITAL, ETC.

I take pleasure in bringing to your notice a drug which has recently been the subject of considerable experimentation as regards its anti-malarial properties, but which has not as yet been tested, so far as I know, in our own country.

The pambotano, or Calliandra Houstoni (Baillon), is a small tree, growing from three to five feet high, and is found principally in Mexico, where it seems to have possessed considerable reputation for its medicinal qualities.

It was first prominently brought before the attention of the medical profession through an article of Dr. J. Valude, which was presented to the Academie de Médecine of Paris by Dr. Le Roy de Mericort, on the 19th of November, 1889, and which resulted in a report on the subject by the Academie on February 18, 1890.

In this report Dr. Dujardin-Beaumetz, although doubting the ability of this drug to replace quinine, admits of its apparent value, and suggests the necessity for further experiments in this direction. Dr. Villejean, in a chemical analysis of the plant, has, as yet been unable to isolate its active principle, but notes the presence of a peculiar tannin, which yields a dark-green precipitate with the perchloride of iron, and thus closely resembles the tannin of catechu and cinchona.

Dr. Valude uses a decoction and alcoholic elixir in doses of 70 grammes for an adult, and 35 grammes for a child under twelve years of age. One litre of this solution should be divided into four doses, and taken within

* Read before the Phila. Co. Medical Society.

the twenty-four hours, each dose to be sweetened and drank hot. His report comprises personal observations of fifteen cases of malarial fever, besides a *résumé* of the results obtained in Mexico, Japan and Italy. Of the fifteen cases in question seven were complicated by other diseases, such as la grippe, tuberculosis, grave anæmia, and in one case by intermittent dental neuralgia. In these last cases the periodical attacks were suppressed, while the results in the uncomplicated cases were uniformly successful, and in the majority of instances but one dose of pambotano was necessary to effect a cure.

The following observations are related in detail:

Case I.—Girl of sixteen years, very anæmic quotidian, fever beginning May 17, 1886, at 2 o'clock, and becoming permanent with exacerbation the following day at 2 o'clock. Continual headache, which increases at time of access. Decoction of pambotano May 22d. Vomiting at the second dose. Nausea with first dose. Cephalalgia disappeared after first dose. Since that time the fever has not returned.

Case II.—Child of twelve years; same type as above, with violent cephalalgia, which is worse at the beginning of fever, 4 or 5 o'clock in the evening. Decoction of pambotano the fourth day of the fever. Nausea and vomiting after first dose. At third dose child vomited food taken one hour before, but no medicine. Food taken twenty minutes after the last dose, was followed neither by nausea nor vomiting. The bowels were opened after the first two doses. The headache disappeared after the first. At 4 o'clock the fever did not return. Two doses alone had been absorbed. The cure was definite.

Case III.—Man of twenty-two years, suffering from intermittent fever contracted at Tonquin. Four different attacks while at Tonquin at two or three months interval (in September, December, February, April.) Returned to France in May. Return of fever in July, tertian type. Decoction of pambotano the day of the attack. Some nausea, no vomiting. After the first dose the headache disappeared. The fever did not return. Fifteen months afterward the cure was maintained, and the fever which had previously returned every two months had not reappeared.

Case IV.—Man of forty-four years. Subject to the tertian fever, two attacks of which have been treated by quinine. At the third attack decoction of pambotano. Some nausea. The fever has not returned.

Case V.—Woman, forty-eight years of age; quotidian type, commencing at noon with a violent pain on the right side. The elixir, containing 50 grammes of the root. was given on the 30th of March. Some nausea. One passage after the first dose, which caused the disappearance of the pain above-mentioned. At 1 o'clock the customary chill did not appear, but a slight elevation of temperature was noticed. On the 31st of March the fever returned to a slight extent. On the 2d of April no fever, but the appetite was poor and the tongue coated. After the 3d of April the fever no longer returned.

Case VI.—Man, forty-six years of age. First attack. Suffering for eight days from well marked attacks,with violent cephalalgia. Decoction of 70 grammes of pambotano. No bad results. At noon, the customary hour for the chill, nothing was noticed, notwithstanding that only two doses had been taken.

The following cases have also been collected by Dr. Valude:

Dr. J. M. Bandera, of the University of Mexico, after carefully testing the drug in various Hospitals, declares that he has obtained excellent results, even in cases which had not yielded to the use of quinine.

Professor J. D. Campuzano, of Tacubaya, as well as Dr. J. B. Lobato, report excellent results.

The government of Guanajuato appointed Drs. J. Hernandez, R. Lopez, and T. Dominguez to officially report on the merits of pambotano, and after careful experiments these gentlemen reported marked success.

Dr. Lafont reports having treated the Conseiller-general of French Guiana, who had suffered from a severe type of malarial fever for five years, which had resisted the use of quinine, arsenic, as well as a long sojourn at Vichy. One dose of pambotano was sufficient to effect a cure, which is maintained until the present time.

In the province of Salto, Argentine Republic, Drs. C. Coates, J. Tedin, and A. Valdez have treated numerous cases of malarial fevers, some of which were uninfluenced by the administration of quinine, but all of which yielded to the use of pambotano.

Concerning the results obtained by its use in the French and German Hospitals at Yokohama, Japan, the Belgian minister reports that in all the cases a cure resulted within forty-eight hours.

Dr. A. de Cadilhac, an Italian physician, reports the cure of a case of obstinate malarial fever contracted in the neighborhood of

Rome, which had resisted the use of strong doses of quinine.

Dr. Betances, now of Paris, reports three cases of severe malarial fever, contracted at Panama by employes of the Canal Company, which had totally resisted large doses of quinine and arsenic, as well as the douche treatment. In each case one dose of pambotano resulted in a permanent cure.

Dr. Depeton, practising in the Basses Pyrinées gives a history of three cases, with an equally successful termination.

Dr. De Chapelle, of Bordeaux, reports a case of quotidian intermittent, in a patient seventy-two years of age, where quinine at first yielded good results, but afterward lost its effect. The patient was in a desperate state when he was placed upon one day's treatment of pambotano, which resulted in a total cure.

Since the collection and publication of these statistics numerous cures have been reported by physicians in different parts of France. The results, as reported, are so uniformly successful that the question arises whether a certain allowance should not be made for the enthusiasm which so generally attends the introduction of a new remedy.

Still more recently (*La Tritum Médicale*, April 30, 1891) Dr. J. Pelletan reports the case of a man, thirty-eight years of age, who contracted repeated attacks of malarial fever of divers types while living in various parts of South America. Returning to Paris some years since the fever reluctantly yielded to the quinine treatment, but was followed by obstinate neuralgias in various parts of the body, and particularly by an atrocious sciatica, which caused the most intense suffering.

Notwithstanding the most varied forms of treatment, nothing afforded even temporary relief, except hypodermics of morphia.

The patient at this time has marked emaciated complexion of a pasty yellow with a parchment-like skin, presented a cachectic appearance, and the spleen was markedly enlarged. No history of syphilis or alcoholism.

On the 19th of January last he was ordered a dose of pambotano (Midy).

Up to the present time (April 20th) he has been entirely free from all pain, notwithstanding that he was exposed to the inclement weather of a Paris winter.

My own observations are limited to eight in number as far as the malarial fevers are concerned. Each of the above cases, however, was carefully observed for a varying period of time before the administration of the medicament in order to insure accuracy of diagnosis. I have also observed its results in other diseases, such as la grippe, typhoid fever, phthisis, etc., but, frankly speaking, no influence could be detected upon the course of these different maladies.

The preparation used in these cases was an alcoholic elixir prepared by Midy, of Paris, and kindly furnished me for the purpose by Riguad and Chapoteaut. Each bottle of the elixir contains 90 grammes, representing 70 grammes of pambotano. The contents of each bottle is to be administered in four equal portions within the twenty-four hours in hot sweetened water or tea, and preferably taken on an empty stomach.

The cases are as follows:

Case I.—A clergyman, forty years of age, contracted a quotidian intermittent while on a gunning trip in Virginia, six years ago. Since that time he has, without exception, been subject to a renewal of the attacks every spring, and occasionally in the fall of the year. These attacks yield to treatment by large doses of quinine and arsenic, but generally incapacitate him from work for a period of about two weeks. His present attack commenced with a chill on March 2, 1891, at 4 o'clock in the afternoon, followed by a temperature of 104°, and a return of the same symptoms on the succeeding day. He commenced taking the elixir of pambotano on the 4th of March, but experienced a modified chill on the afternoon of the same day; temperature 102°. Some nausea after the first dose. Since that time he has had no return of the above symptoms.

Case II.—Girl, aged seventeen years, employed in a mill, residing in the southern section of the city, presented herself at the Southwestern Dispensary with the history of having had a chill on the previous day followed by fever and sweating. Temperature at the present time normal, but patient feels weak and languid; tongue coated. She was directed to return the next day. On this occasion the thermometer marked $102\frac{2}{5}$.° She commenced the pambotano the same afternoon, taking two doses on that day, and two the day following. The first dose was vomited within fifteen minutes, but the subsequent doses were retained. She remained under further observation for ten days, with no return of the fever.

Case III.—Woman, aged thirty-seven years, dressmaker; has had attacks of quotidian intermittent in the spring of the year for the last four years, which kept her confined to the house for about ten days on each occasion. Was taken with a chill March 24th, followed by the regular symptoms,

which were again repeated the next day. Commenced the use of pambotano March 26th. Some nausea after each dose, but no vomiting. Bowels open three times during the course of the day. Resumed her occupation on the 27th, and subsequently reports (June 8, 1891) that she had been entirely well ever since.

Case IV.—Commercial traveller, aged twenty-five years. While in Florida last autumn he was taken ill with a severe type of remittent fever, which confined him to the hotel for a period of seven weeks, and which finally yielded to large doses of quinine and arsenic. Present attack commenced April 3d with chill, fever, intense headache, coated tongue, nausea, and some vomiting. Commenced the pambotano on April 4th; the patient vomited the second, third, and fourth doses. On evening of same day he was given three grains of calomel in divided doses, to be followed by a saline. On the morning of the 5th, the fever still being present, the drug was ordered continued as on the previous day, but he again vomited the first and third doses, besides which the bowels were opened at least a dozen times. On the 6th the patient appearing no better, and the irritability of the stomach still being present, he was placed on suppositories of quinine, together with the use of Fowler's solution internally. After further treatment of about a week, the patient entered into a rather slow convalescence.

Case V.—A woman of thirty-five years, with a distinct malarial history, had been under my care for over a year suffering from severe attacks of neuralgia in various parts of the body, but particularly of the facial type. Rarely a week passed without severe suffering on her part. Quinine, arsenic, antipyrin, and the general routine treatment, including electricity, had been without any permanent result; the same may be said of the extraction of several decayed teeth. Commenced taking pambotano on April 6th without suffering any inconvenience from the drug. The pains disappeared to a great extent until April 18th, when she experienced another attack, but milder in character, according to her testimony. Another dose of pambotano was administered April 19th, since which time she has been free from pain, with the exception of slight twinges occurring in damp weather.

Case VI.—Laborer, aged forty years, applied at my service at the Howard Hospital, May 2, 1891, with a tertian intermittent, the result of an attack contracted four years ago, and which has since visited him every spring and fall. Commenced pambotano the next day, since which time the fever has not returned.

Case VII.—Laborer, aged thirty-five years, applied at the Howard Hospital May 22d, with a tertian intermittent, which, he thinks, he contracted while digging at Greenwich Point. Some irritability of the stomach being manifested, small doses of calomel were ordered for that day. Commenced pambotano on the 23d, but vomited the third dose. Slight chill on morning of the 24th. Drug continued during the day, after which no further treatment was necessary.

Case VIII.—Laborer, aged thirty-two years, applied at the Howard Hospital, June 2d, with quotidian type of fever, headache, vomiting and diarrhœa. Commenced pambotano June 3d, but vomited each and every dose. Drug continued June 4th, and only the last dose was vomited, but the number of intestinal movements were greatly increased and accompanied by some griping pain. The fever not being apparently influenced, he was placed under large doses of quinine, and is now entering convalescence.

As will be seen by the above my results, although decidedly encouraging, are hardly as satisfactory as some of the reports from abroad. In the two cases where the exhibition of the drug remained apparently without result, the question may arise as to whether a sufficiently large quantity was really absorbed on account of the gastro-intestinal irritability. Indeed, this undesirable feature seems to play a more or less important part in most of the cases.

For the above reason it would seem especially desirable that an active principle should be isolated. And we can only wonder that this has not already been accomplished in a drug whose action seems to be sufficiently pronounced to obtain results within such a comparatively short period of time.

In conclusion, it would seem to me that the results already obtained are sufficient for further work in this direction, especially as no opportunities for observing malarial fevers are better than those of the French physicians.

SCURVY.

Tschelzoro considers an absolute milk diet a specific for scorbutus. He begins with about four glasses of milk a day, and increases this quantity at the rate of a glass every day or two.—*Ex.*

Special Correspondence.

London Letter.

THE GENERAL MEDICAL COUNCIL AND THE FIFTH YEAR OF MEDICAL EDUCATION—THE LIVER AND "LIVERISH" PATIENTS—HEART MURMURS—DOCTOR WILKS ON VENESECTION—BRITISH MEDICAL ASSOCIATION—SIR RICHARD QUAIN ON PERSONAL APPEARANCE AND HANDWRITING.

On meeting for the fiftieth session that important body, the General Medical Council, proceeded to elect Sir Richard Quain to the post of President, rendered vacant by death of the late Professor Marshall. A good deal of discussion took place as to the disposal of the fifth year of study, already adopted by several leading bodies, as the London College of Physicians and the University of Edinburgh. Everyone seems to agree on the necessity of devoting the additional twelve months to practical work of some kind, but there are a variety of opinions as to what branch of the curriculum should be specially favored. For a long time past attention has been called to the fact that the present provision for training in practical midwifery is a snare and a delusion, and a motion was laid before the Council proposing six months compulsory attendance at a lying-in institution. It was pointed out that the standard of professional requirements had everywhere been raised, except in that particular branch. One of the speakers, Mr. Wheelhouse, of Leeds, insisted upon the unspeakable importance of a knowledge of midwifery to the general practitioner. In the course of a long career the latter might not encounter a single surgical case of importance, but he was certain, on the other hand, sooner or later, to meet with the dangerous complications of labor. Most people will agree that a radical defect of modern medical education is its want of what the irreverent youth of the day would call "common garden" training. There is a tendency to avoid homely and everyday ailments, while students are duly impressed with a minute knowledge of such rarities as myxœdema and acromegalie. Who, as some one has most pertinently inquired, has ever, as a student heard a lecture on biliousness? Yet functional hepatic disturbances, which are simply protean in their nature, will be found to enter largely into the domain of actual practice. In surgery, again, a student is taught the different ways of ligaturing arteries, operations about the foot and ankle, and amputation through the hip-joint; but when will the ordinary practitioner be called upon to tie a large artery or to perform a major amputation? As a test of the weak-kneed nature of examination-room knowledge, it would be interesting if a round hundred or so of the leaders of the profession could be publicly put through their paces before a high standard examination body.

Of course, no one questions the value of a sound and thorough medical education. The whole matter, however, has been allowed to get too much under the control of examiners and of licensing bodies. Professional interest has now been thoroughly awakened, and it is to be hoped that the rectifying of manifold errors will be so many steps toward the attainment of a more perfect ideal.

That important organ, the liver, is now as much neglected as it was formerly set up in high places. In many large hospitals one may see diagnosis of all kinds of disease, general and special, but rarely any mention of the liver, except for such conditions as atrophic cirrhosis or obvious enlargements. This points to an unmerited degree of neglect, which is no doubt chiefly owing to a rebound from its former popularity. In the good old days the long-suffering organ in question, covered a multitude of sins, and was, indeed in many cases, a refuge for colossal ignorance. That these traditions are not altogether dead is shown by the following anecdote, the truth of which is vouched for by a student of University College. My informant went to take charge of a practice, and received the concise directions from its owner. "My patients are divided into three classes. The first have nothing the matter with them, these you will soon be able to single out. The second lot suffer from 'liver,' and those you will have no difficulty in distinguishing. The third class are made up of those who, while not suffering exactly from 'liver,' may be all brought together under the term 'liverish'." And then the worthy and hard worked practitioner—he had an extensive practice,—went far away for his annual fortnight at the seaside.

It is well known that of late years many of our ideas regarding the significance of heart murmurs have been variously altered and modified. Right-sided dilatation, for instance, is said to be quite as often shown by pulsation in the third, fourth, and fifth interspaces to the left of the sternum as by the epigastric pulsation on which we were

wont to rely. Tricuspid murmurs, again, are held to be common instead of rare, a fact which is accounted for by their extreme inconstancy and fleeting nature. There is one point, however, on which all the text-books seem to have agreed, namely, that the presystolic murmur is strictly localized to the apex. A distinguished Edinburgh professor now comes forward to dispute that statement. He states that the murmur is often heard over the whole left border of the heart, and also over that portion of the front aspect corresponding to the mitral orifice.

The proper place of phlebotomy in medical practice is far from being settled. Dr. Wilks has lately contributed a very interesting paper on this subject to the *Lancet*. He quotes several cases where venesection gave relief in apparently desperate circumstances, of which the following may be taken as a sample. "In uræmic convulsions the effects are very striking; the right heart is relieved, and poisoned blood removed from the system. One case of this kind, indelibly fixed on my memory, is that of a neighboring dressmaker, who I believe is still alive. I was asked a few years ago to see this patient early one morning by her medical attendant as a satisfaction to himself and to her friends; she had been in convulsions all night, but he did not wish to disturb me before daybreak believing the case to be hopeless. I found a middle aged woman in constant convulsive movements, froth issuing from her mouth, quite comatose, and almost pulseless. The whole body was livid and the extremities cold. The doctor said she was dying, and therefore allowed me to bleed her. I took away a small wash-hand basin of blood, and while flowing the lividity passed off, the convulsions ceased, the body gradually became warmer, and when I saw her in the middle of the day she was calm, and conversed with me. Her life was as clearly saved by the bleeding as if I had dragged her drowning out of the water; and this is more than I can say from the use of drugs." No doubt in many cases of uræmic convulsions the effects are marvellous, still one would hesitate before carrying out this plan of treatment on emaciated and anæmic individuals. There can be little question of its value in impending death from paralysis of the heart, resulting from distended right side. The medical practitioner is only too familiar with the gasping struggles for breath, the blue face, and the distended veins, marking right-sided distension, and would gladly welcome any therapeusis consistent with safety. Besides the general lowering of blood pressure afforded by venesection, proposals have been made from time to time to give direct relief to congested organs. Not long since a medical man published an account of a plan for abstracting blood from the lungs which he had discovered by accident. Briefly expressed, his method consisted in plunging an ordinary perforated aspiration needle into the lung, where it was allowed to remain until there was a free flow of blood. The hæmorrhage was arrested by first plugging, and then slowly removing the tube, so as to allow a clot to form and remain *in situ*. Direct withdrawal of blood from the liver is effected by incision, hepatotomy, or more preferably by a long curved trochar needle. Then there are the other methods of local abstraction, cupping and leeches. One can hardly imagine the modern student up for an examination deigning to mention either of these time-honored modes of treatment.

The entertainment committee of the British Medical Association is able to announce a most alluring programme, including picnics, garden parties, and receptions galore, to say nothing of a ball given by the Mayor and Corporation of Bournemouth. That town is the centre of a number of places of interest, such as Weymouth, Portsmouth, Swanage, Portland, Christchurch, Wimborne, the Isle of Wight, and that ancient prehistoric monument, Stonehenge. All of these, as well as others not mentioned, can be reached by excursions, and at many of them receptions will be given by residents in the neighborhood. All these social enjoyments, however, will be eclipsed by the magnificence of the International Congress of Hygiene, which follows the association gathering at an interval of a week.

Everyone knows the advantage of a good bedside manner to the physician. In his chatty address to the students at University College, Sir Richard Quain told how its need was impressed upon him at an early stage of his career. When quite a young man he was placed in temporary charge of a patient, and full of the weight of his unaccustomed responsibility, his countenance grew longer and longer. When he was leaving one day the lady's husband followed him. "I greatly appreciate the anxiety you feel for my poor wife," he whispered, "but please don't let her see it again, for after you had left the room she asked me if you were the undertaker." Sir Richard told another little anecdote, also against himself. Once as a student he went up for an examination. He had read hard and felt that he knew his subject, so that his surprise was great when

he found he had not won the medal. Subsequent inquiries revealed the fact that the examiner had awarded his paper a certificate on the strength of the one answer he had been able to read; but the rest of the paper had been marked as totally illegible. How is it that doctors write so badly as a class? there must be some explanation somewhere. Talking of examiners and bad writing reminds the writer of an incident at a public school where the head master returned some papers with certain hieroglyphic scrawls on the margin. The united wisdom of his classmates at length deciphered the description, which contained a simple comment to the effect, "writing very bad." D. W.

London, June 7, 1891.

SELECTED FORMULÆ.

PRURIGO.

The following prescription is useful in the treatment of prurigo:

℞
Resorcini.....gr. xxxv.
Sulphur præcipitat.....ʒ v.
Acid. carbolic.....
Acid. salicylic.....aa gr. vij.
Chloral.....gr. xx.
Vaselini.....ʒ iss. M.
Sig. Use externally.

—*La Semaine Médicale.*

SEDATIVE FOR BABIES.

Dr. Van Goidtsnoven, of Atlanta, gives a formulæ with which he has had most gratifying results in restlessness, spasms, deliria, and in all cases requiring a sedative, anodyne, anti-spasmodic or somnifacient.

℞
Camphor. monobromat.....gr. xvj.
Ext. hyoscyami fl.....gtt. xvj–xxx.
Syrup lactucarii (Aubergier's).....fʒ viij. M.
S. A tablespoonful every hour till relieved.

—*Dixie Doctor.*

NEURALGIC HEADACHE.

Dr. E. P. Hurd, in his monograph on neuralgia, advises the following prescription for headaches of all kinds:

℞
Caffeini citrat.....
Ammonii carb.....aa ℈ j.
Elixir guaranæ..... ʒ j.
M. Sig. ʒ j every hour until the pain is relieved.

TREATMENT OF FISSURE NIPPLES.

℞
Balsam of Peru,
Tincture of arnica.....aa ʒss.
Oil sweet almonds..... ʒj.
Lime water..... ʒss.
M. Apply a small quantity several times daily.

ANATOMICAL PRESERVING FLUID.

The following is the formulæ of Rosenthal's liquid for preserving anatomical specimens:

℞
Muriate of quinoline..... 5 parts.
Marine Salt..... 5 "
Glycerin.....100 "
Water.....900 "

The only inconvenience attending the use of this solution is that it takes out all the coloring matter, the specimens assuming a very pale hue.—*St. Louis Med. and Surg. Jour.*

CREOSOTE EMULSION.

℞
Creosoti.....gtt. xvj.
Olei carophyl.....gtt. viij.
Olei cinnam.....gtt. iv.
Olei menth. pip.....gtt. iv.
Olei olivi..... ʒj.
Mucil. acaciae.....ʒiv.
Aquæ.....ʒvj.
M. Ft. Emulsionem.
Adde.
Glycerinae.....ʒiv.
Aquæ q. s. ad.....ʒiv.
M. Sig. ʒi. represents gtt. j. of creosote.

—*Western Druggist.*

WINE LEMONADE.

Dujardin-Beaumetz (*Bul. Gén. Ther.*) recommends a vinous lemonade to promote diuresis in typhoid and other fevers, and gives the following:

℞
Red wine..... .....O ss.
Tartaric acid.....ʒ ij.
Water.....O iss. M.

Laillez recommends the following:

℞
Syrup of citric acid.....ʒ ij.
Red wine.....ʒ viij.
Essence of lemon..... ♏ xv.
Water. .....O ij. M.

TREATMENT OF ERYSIPELAS.

This is the treatment Talamon also employs in cases of pustular variola. It consists in spraying with Richardson's apparatus for a minute the outer ring, both within and without the erysipelatous swelling, with the following solution:

℞
Corrosive sublimate } of each 15 grains.
Tartaric or citric acid }
Alcohol (90 per cent.).....1½ drachms.
Sulphuric ether enough to
make.....3 ounces 1 drachm. M.

This solution being caustic should not be thrown into the eyes nor in proximity to the nostrils. Spraying should be repeated two or three times a day.

Cayet considers this as the best remedy employed against erysipelas. If it is used in the beginning, the inflammation will yield during the first day, and the disease will be terminated by the fourth day.—*Revue Général de Therapeutique et de Clinique.*

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

EDWARD T. REICHERT, M. D.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF PENNA.,
EDITOR AND MANAGER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

THE MEDICAL AND SURGICAL REPORTER.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent 3 months on trial for $1.

At the termination of the period of subscription, we will promptly discontinue sending THE REPORTER unless directed to the contrary by the subscriber.

Remittances should be made by draft, check, postal note, or money order payable to Edward T. Reichert.

THE POCKET RECORD AND VISITING LIST.

Two sizes. Prices to subscribers of THE REPORTER: For 30 patients a week (with or without dates), $1.00. For 60 patients a week (without dates), . . $1.25. Prices to non-subscribers, $1.25 and $1.50 respectively.

THE MODEL LEDGER.

Physicians who keep their own books will find this of great value. Sample pages sent on application. Price, $5.00.

☞ SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If THE REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS.

Write in ink.

Write on one side of paper only.

Write on foolscap or legalcap paper.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be pleased to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

LEADING ARTICLE.

THE PRESENT POSITION AND SCOPE OF LITHOLAPAXY.

The operation of litholapaxy is a vast improvement over the old-fashioned lithotrity in which the stone was crushed and allowed to come away with the urine, or, in which the crushing of the stone occupied several sittings.

Litholapaxy combines the operation of lithotrity, or the crushing of the stone, with the immediate evacuation of the fragments. The objections urged against the single sitting with aspiration of the detritus, are: that urethral and vesical irritation is caused by the repeated passage of the lithotrite and of the tubes for aspiration; that violence is inflicted upon the bladder by the beak of the lithotrite in the many seizures of calculi fragments; that the friction and perhaps erosion of the mucous membrane by angular fragments during the search for the broken particles is injurious; and, finally, that the severe aspirations with the sudden and frequent distensions of the bladder are harmful. In our opinion, such arguments are erroneous when applied to litholapaxy as performed by a careful and experienced surgeon. When such damage is possible, the case is not one for a non-cutting operation but calls for a lithotomy. Recognizing that litholapaxy is not an operative procedure for indiscriminate use, but rather one applicable to a limited class of cases, we find that statistics, which are daily accumulating, bear ample testimony to the fact that the operation is no longer a novelty, but occupies a most favorable position in the surgical treatment of stone in the bladder.

In a recent number of the *British Medical Journal*, (May 9, 1891,) Dr. J. A. Cunningham speaks of litholapaxy as "*infinitely safer than any variety of lithotomy for suitable cases.*" His estimate for cases suitable for the operation is "*about* 90 *per cent. of all cases.*" The great advantage which this surgeon claims for litholapaxy over lithotomy is "that the patient is laid up for about four

days instead of three weeks, after the operation." This same authority gives a series of 102 cases of stone in the bladder, removed by him by the operation of litholapaxy, since January, 1890, *without a single death.* The weights of the stones removed varied from a few grains to over two thousand; their composition included nearly all the known varieties. The patients' ages ranged from 2½ to 70 years. The time occupied in an operation covered from a few minutes to an hour, the average being about nineteen minutes, and the average stay in the Hospital about six days.

Dr. Cunningham calls attention to a noteworthy feature in his series of reported cases, which is that in four of the cases, three of them with phosphatic stones, an operation had been performed within a short period for removal of a similar stone. If all these had been previously operated on by the crushing process, the author states "that it would have made a strong case for those who hold that formation is very likely to recur after crushing, fortunately, however, two of them had been operated upon by lateral lithotomy."

In the same Journal (*loc. cit.*), Dr. G. H. D. Gimlette publishes a paper entitled "Forty Successful Cases of Litholapaxy in Boys." The children's ages ranged from 2 to 16 years. The stones removed were of various composition and weighed from 6 to 395 grains. The number of days' stay in Hospital ranged from 2 to 15, the average being about 7.

Dr. P. J. Freyer, (*loc. cit.*) publishes a series of 165 consecutive cases of litholapaxy, in which occurred but three deaths. Amongst these 165 cases there were 99 adults—96 males and 3 females—and 66 male children—lads up to the age of 15 years. The ages of the adult males varied from 18 to 90, and of the male children from 2 to 15 years. The average number of days the patients were under treatment was, in the case of adult males, 6, varying from 2 to 28; in the case of male children, about 5½, varying from 2 to 21; and in the case of females, 4. The average weight of the *débris* of calculi removed was in adult males 242 grains, varying from 3 grains to 3 ounces and 1 drachm; in children 108 grains, varying from 2½ grains to over 3 ounces; and in women 435 grains. The weights given are those of the dried *débris.*

After a careful study of the 307 cases of litholapaxy as represented in the above quoted papers, we find that the operation was performed irregardless of the age of patient and the size or variety of the calculus present; also that but three deaths occurred in the entire series of cases—less than one per cent. Surely such a showing must commend the operation as a safe and simple procedure in experienced hands, and to be recommended in such cases where the stone is not very hard and is of moderate size; when the bladder is in a fairly healthy state, that is, free from tumors, not dilated or sacculated, or in the reverse condition, irritable, contracted, and with hypertrophied walls.

This then is the present position and apparent scope of the operation of litholapaxy, the results of which have not been equalled in any other large and important operation in surgery, and is entirely due to the introduction of Bigelow's method. Death has removed this great surgeon from our midst, but his name is imperishably associated with the modern operation for urinary calculi, and with the name "litholapaxy," which he introduced to denote and distinguish it.

Correspondence.

Editor of the Medical and Surgical Reporter.

Dear Sir:—In reference to the priority of use of the arsenite of copper in the treatment of diarrhœa permit me to mention a few historical facts. In the translation of *Jahrs Symptomen Codex* published in 1865 there is recorded a fragmentary proving of the arsenite of copper, from Noack & Trink's Handbuch, in which diarrhœa is mentioned and for which it must, under the law of similars prove curative. In 1868, W. James Blakely, M. D., read a paper upon the effects of the arsenite of copper, before the Homeopathic Medical Society of Pennsylvania, in which he referred to the same fact. In

January 1873, J. H. Marsden, of York Sulphur Springs, published in the *Hahnemannian Monthly*, an article upon the clinical uses of the arsenite of copper in which he refers to the cure of a case of diarrhœa by this remedy. In 1873 W. H. Holcombe, M. D. of New Orleans, published in the *Medical Investigator*, an article in which he called attention to the fact that the arsenite of copper had proved very useful in the choloraic diarrhœa prevailing during the summer of that year. In *Hering's Guiding Symptoms*, 1887, may be found the symptoms which had received clinical verification by Marsden and Holcombe. Trusting that you will give these facts to the profession that honor may be done Blakely, Marsden, Holcombe and other early investigators of this most useful drug,

I remain respectfully,

AUG. KORNDOERFER, M. D.

1728 Green Street, Philadelphia.

BOOK REVIEWS.

SEVERE VOMITING DURING PREGNANCY. By Graily Hewitt, M. D., F. R. C. P., Emeritus Professor of Obstetric Medicine, University College, London, etc., 8vo. pp. 148. London. Longmans, Green & Co.

This monograph will prove of great interest and value to every one interested in obstetrics. It is true it is a special plea for the author's theory concerning the causation of the severe or pernicious vomiting of pregnancy, but this plea is based upon a series of 120 cases of severe vomiting of pregnancy, which are given in detail. Those who do not accept the author's conclusions, will be greatly benefited by studying his material. Hewitt concludes that the severe vomiting of pregnancy is due usually to flexion of the uterus, incarceration of the uterus, or to rigidity of the cervix. In the chapter on treatment a careful review of the various methods of treatment which have met with favor will be found.

MASSAGE—A Primer for Nurses. By Sarah E. Post, M. D. Second edition, with seven original photo-plates. The Nightingale Publishing Co., 1891.

The author of this little volume shows herself to be perfectly familiar with her subject, and within the compass of fifty pages has outlined the various methods of giving both local and general massage, with full directions in regard to the management of the patients, the length of application, the Weir Mitchell treatment, etc. To those for whom the book is intended, or to others interested in the subject, the work will be found to contain all the information desired.

PERISCOPE.

THERAPEUTICS.

BORAX IN THE TREATMENT OF EPILEPSY.

Borax was proposed for the first time by C. Folsom in the treatment of epilepsy in 1881. Gowers reported four cases treated with this remedy, out of which in three a cure was obtained. Dr. Dijoud (El Siglo Medico, 1913, 1890) has tried it in twenty-five chronic epileptic patients in which the bromides had been used either without success or with no satisfactory results. The duration of the treatment was from four to seven months; the dose varied from one to six grammes daily. He entirely cured one, and notably relieved all the others, except six. From this it is apparent that borax is able to diminish—in a great number of cases which do not yield to the bromides—the frequency of the epileptic attacks. The dose may, without inconvenience, be carried up to six grammes per day, yet one should be careful to commence with one to two grammes daily, and progressively increase the dose. The following is a convenient form for a one to four-grammes dose:

℞ Sodii biborat, pulverizat.,.. ..... 1-4.00
Syrup corticis aurant,..... 30.00
Aquæ destillat.,..... 100.00 M.
Sufficient for one day.
SIG.—To be taken in two doses; one in the morning, and the other in the evening.

When the dose exceeds four grammes per day, one gramme of glycerin should be added for every gramme of borax over four grammes.

In the prolonged use of the remedy Dr. Dijoud recommends the following formula:

℞ Sodii biborat, pulverizat..... 10.00
Glycerine pur.,..... 6.00
Syrup corticis aurant,..... 94.00 M.
SIG. To be taken by the spoonful.

—*Journal of Nervous and Mental Diseases.*

THE THERAPEUTICS OF PAPAIN.

The uses to which the so-called digestive ferments can be put seem to be increasing, more particularly in regard to papain, the vegetable ferment obtained from the juice of *carica papaya*. As a remedy in indigestion it has the unquestionable advantage over similar bodies of animal origin of carrying on its action in an alkaline, an acid, or a

neutral medium indifferently. Its action on food is, therefore, not limited to any particular region of the alimentary canal but continues so long as there is food to be acted upon, whether in the stomach or intestines. Its action on diphtheritic exudative membranes again is extremely interesting, and since it has been demonstrated bacteriologically that the specific bacilli thrive and multiply therein, the propriety of removing the membranes as they form has been established on a scientific basis. Hence the solvent action of papain on these membranes is a valuable addition to the resources of the practitioner in dealing with this disease, for it is not only more promptly effectual, but is free from the suffering which is caused by the brutal practice of removing the exudation by violent rubbing or *grattage*. The subjacent mucous membrane is thus denuded and rendered accessible to local treatment of another kind, and the throat is prevented from continuing to be a focus for the elaboration of the diphtheritic poison. Still more recently these dissolving properties have been turned to account for the purpose of bringing about the arrest of growth, and even the retrogression, of malignant neoplasms, and although this plan of treatment has not yet received official sanction it is claimed to have yielded good results in the hands of competent observers, and it is sure to be admitted to the test of practical experience. These bodies belong to a class of agents in respect of which the scientific chemist is significantly silent. The property which they possess of causing chemical change in bodies with which they come into contact without the ratio of quantity and effect which obtains elsewhere in the chemical world without themselves undergoing any change, is a curious and hitherto unexplained phenomenon. It is not improbable that in the future these powerful qualities may find a much wider application in therapeutics than is at present the case, and the benefits should be commensurate with the intensity and comprehensiveness of their effects.—*Medical Press.*

SALICYLATE OF SODA AS A CHOLAGOGUE.

Prof. Germain Sée, in an article on hepatic colic, published in the *London Lancet*, calls special attention to the use of salicylate of soda, which he has found to be the most efficient of all cholagogues in promoting the expulsion of gall-stones. The well known cholagogues were found worthless in the ailment, for they stimulate the biliary secretion by increasing the solid elements, which is not desirable.

Salicylate of soda stimulates the biliary secretion by increasing its fluid element, which is the principle indication in the expulsion of gall-stones.

The cholagogue property of salicylate of soda was made known by Rutherford, but has not received much attention; with the additional recommendation of Prof. Sée, supported by his vast clinical experience, the remedy should be considered worthy of trial.—*New Remedies.*

THE ABSORPTION OF DRUGS FROM OINTMENTS.

Huff summarizes the results of his experiments on the absorption of drugs from ointments, with the bladder of goats, as follows: With vaseline and iodide of potassium, exosmose commenced at the end of the first hour; with lard and iodide of potassium, at the end of the ninth hour; with lanolin and iodide of potassium, the result was *nil* up to the twenty-fourth hour. With vaseline and carbolic acid exosmose commenced at the end of two hours and three-quarters; with lard and carbolic acid at the end of seven hours; with lanolin and carbolic acid the result was *nil* at the end of twenty-four hours. With vaseline and resorcin exosmose commenced at the end of the tenth hour; with lard and resorcin at the end of the fifteenth hour; with lanolin and resorcin the result was *nil* at the end of the twenty-fourth hour. He therefore concludes that if it is desired to obtain the rapid absorption of drugs into the circulation, it is better to use vaseline, and that for local therapeutic purposes pomades made with vaseline should be preferred. This latter substance causes the incorporated medicaments to keep for a much longer time.

Regarding the effect of age on the absorption of drugs, Dr. Yatsuty conducted some experiments in relation to this subject, in the Zhitomia Municipal Hospital, on healthy male patients of from 8 to 80 years of age, the drugs experimented with being iodide of potassium and salicylate of soda. The dose was made to depend upon the body-weight, a grain being allowed for each 10 kilogrammes. The drug was administered in a gelatine capsule, and then the urine was examined every 3 minutes. When the iodide was given the saliva was examined every 2 minutes, but not in the case of the salicylate, as there was not any evidence of salicylic acid in the saliva. The conclusion arrived

at was that the younger the subject the more rapidly the absorption, as tested by the secretions, occurred. Thus a boy of 9, weighing 25 kilogrammes, taking a dose of 2½ grains of iodide of potassium, generally gave the reaction in the urine in nineteen minutes; a man of 36, weighing 66 kilogrammes, and taking a dose of 6½ grains, showed no reaction in the urine until 31 minutes had elapsed; and a man of 76, of about the same weight, and taking the same dose, showed no reaction in the urine for 37 minutes. Salicylate of soda was absorbed in boys and young men in about 15 minutes, while in middle-aged men it required about 20 minutes, and in old men about 25 minutes. There were, however, a few exceptions, so that, although the average rapidity of absorption distinctly diminishes as age advances, it is not possible to say with certainty that a particular individual will absorb one of the drugs mentioned more rapidly than another individual who is a great deal older.—*Pharm. Era.*

SERIOUS SYMPTOMS FOLLOWING MORPHIA AND COCAINE.

Dr. Julio San Martin, of Havana, describes in the *Chronica Medico-Quirurgica* a somewhat singular case, where very serious effects followed the application of morphia lotions, associated with cocaine ointment, to the vulva, in the case of a stout lady who had for some years been the subject of diabetes. At the time when the above medication was prescribed there was a considerable quantity of sugar in the urine, the amount passed varied from one to four litres in the twenty-four hours, and the pruritus had become unbearable. The treatment was found to give so much relief that the patient began to resort to it five or six times a day. Very soon she began to suffer from sleeplessness, general excitement, and restlessness, and a terrible sense of impending death. There were, too, delusions—as, for example, that the right side was paralyzed, which was not the case. She complained of a sensation of pricking in both arms, and of something which she thought was the "bone of the heart" moving about inside the chest. Once these symptoms were so severe that Dr. San Martin was called up at night. He gave some bromide at first, and, after having ascertained that the urine contained a trace of albumen and nearly 8 per cent. of sugar, prescribed chloral and morphia internally. This treatment unfortunately appeared only to produce an exacerbation of the excitement, and it then occurred to him that the symptoms might be due to the previous medication. Drugs were therefore given up and recourse had to hot baths, under which the patient became much calmer and improved in every way, even the sugar in the urine decreasing in a very marked degree. Dr. San Martin has frequently prescribed morphia or cocaine for the severe pruritus vulvæ sometimes observed in diabetic patients, without noticing any toxic effects such as occurred in the present case. He remembers two cases in which neither of the two drugs appeared to be of much use by itself, but where a satisfactory cure was obtained for the itching by combining them. The absorption of a sufficient quantity of cocaine to produce toxic effects from an ointment is certainly rare, and Dr. San Martin is disposed to think that in this case the fact of the kidneys having to excrete a large quantity of sugar may have produced a condition favorable to the absorbtion of cocaine, or perhaps that the patient had an idiosyncrasy making her peculiarly susceptible to small quantities of this drug.—*Lancet.*

THE THERAPEUTICS OF OXYGEN GAS.

The medicinal employment of oxygen gas by inhalation has in this country been almost discontinued. Up to quite recently, the difficulty of procuring a supply of the pure gas, and the trouble, delay, and expense attending its administration did much to prevent it occupying such a place in the therapeusis of the practitioner as its known physiological effects warrant. At present, oxygen gas can be obtained from any respectable firm of druggists with the same facility as any other drug. The compressed gas in iron bottles is as portable as a bottle of iodide of potassium, and the apparatus for its administration is inexpensive and more easily managed than another inhaler. Still, the unaccountable fact remains that one of our most active and reliable therapeutic agents is unused, or used so very little that it may be said not to find a place in practical therapeutics. A quick and powerful respiratory and cardiac stimulant, it offers to us the needed remedy in cases of asphyxia, whether resulting from poisonous gases or general anæsthetics; in the suffocative agony of *angina pectoris* its efficiency has again and again been proved, latterly in the well known case of General Philip Sheridan, in which the treatment followed on the lines of the case of Dr. Robert Reid, of Dublin, who in 1817 used and advocated the gas as a

remedy for the disease. Dr. Reid placed several cases on record in which he found oxygen gas by inhalation a very valuable remedy, notably one of a man, æt. 64, who prior to its use had suffered dreadfully from angina. The effect of the gas is, however, only temporary, but there are thousands of cases where temporary aid would save life. In cases of poisoning and anæsthetic narcosis, a powerful stimulant would in many cases be invaluable. How much better a whiff of pure oxygen than artificial respiration in chloral poisoning or chloroform narcosis! Yet with the exception of Mr. Foy's work on "Anæsthetics" and M. Demarquay's "Pneumatology" we are not aware that its use is advocated. Hospitals are provided with electric batteries to resuscitate the asphyxiated and to stimulate the respiratory function, but a more useful and active remedy, oxygen, finds no place in the emergency apparatus of the operating theatre. We hope, however, soon to be able to report that all our general Hospitals are provided with a stock of oxygen gas and a suitable apparatus for its administration. To its value as an antidote in poisoning by carbon gases, especially of the methane series, Colonel H. Elsdale, R. E., bears witness in the present number of the "Nineteenth Century." A man of the Engineer Corps was found apparently dead, "there was no action of the heart that could be felt, and no perceptible breathing." The patient had been inhaling coal gas from a burst balloon for some considerable time, and the Colonel considered that oxygen gas was the most suitable antidote. A tube attached to an iron bottle of compressed oxygen gas was placed in the man's mouth. "The effect of the oxygen was to cause him instantly to revive and clutch the nozzle of the valve convulsively with his teeth." The man who had been "to all appearances dead, presenting the aspect of a livid corpse, his complexion being a ghastly purple or plum color, in perhaps ten seconds, or fifteen seconds at the outside, from the first rush of oxygen into his lungs, was in such violent paroxysms that I was obliged to order four of his comrades to hold him with all their might." Half an hour later the patient was calmly walking back to barracks, all danger being at an end. Such is the report of this most instructive case as given by a practical and educated witness. We commend it to our readers, and especially to those concerned in the administration of anæsthetics.—*Medical Press.*

"Doctor, what do you do when you have a bad cold?" "I cough, Madam."

MENTHOL IN THE LOCAL TREATMENT OF ERYSIPELAS.

Dr. A. L. Benedict, recently reported the admirable results from the use of menthol in erysipelas. G——, a man of middle age, had his first attack of erysipelas eighteen years ago, when the head and face were affected. Six years later the right foot was involved. In 1887 two attacks occurred in the left ankle and foot, there being a period of a week or two between the attacks. In the Spring of 1889, the right foot was again the seat of the disease with considerable lymphangitis along the course of the internal saphenous vein. This attack was treated locally with naphthalin ointment, and it lasted eight days from the initial chill to the defervescence, the highest temperature observed being 104.8 on the fifth day. Eight to ten days was the duration of all the attacks which the patient had experienced, and all of them were of moderate severity.

On February 10, 1891, at 10.00 A. M., the patient was siezed with a chill. He walked home, about a mile, and went to bed. Ordinary domestic remedies and diffusible stimulants were employed but the chilly sensations did not disappear for two hours. Besides the sensation of cold there was violent retching but without emesis.

Partly on account of the writer's lack of faith in internal medication in erysipelas, partly on account of the chronic lithemic condition of the patient and the irritability of his stomach, the treatment was limited, with the exception of a few doses of acetanilid and some other symptomatic treatment, to the local application of a fifteen per cent. solution of menthol in liquid petrolatum. The writer has never heard of such a use of menthol; he was led to try it from its known physiological action and from some practical experience with it in the treatment of conditions of the respiratory apparatus. Most of the essential oils contain some principle which is anæsthetic and antiseptic—actions which are manifestly called for in the local treatment of erysipelas and, therefore, it would not be surprising to learn that others have used menthol in this disease.

After the first thirty-six hours a marked diminution in the rash was noticed, corresponding to the decline of temperature. On February 14th, a small bleb was opened on the great toe, and on the next day no trace of disease remained, except the thickened skin of the foot and an ecchymosis on the great toe, bearing testimony to the original severity of the disease. On the evening of February 15th, the foot was washed with a warm solu-

tion of mercuric chloride (1 : 4000), and for several days the patient was convalescent. Late in the evening of February 20th, the patient had another chill, which proved to be the beginning of another attack of erysipelas, almost identical in its local lesion, temperature, and symptoms with that just described. The menthol treatment was resumed, and the attack had subsided by February 26th.

As far as this case is concerned, the theoretical considerations that led to the adoption of the menthol treatment were supported by the practical result. The patient had never had so speedy recovery under other treatment, and he declared that the usual discomfort and pain attending the attacks were almost entirely relieved by the menthol. The patient's family expressed a decided preference for the odor of menthol as compared with that of naphthalin. The second attack—and that it was a second attack and not a recrudescence is plain when we consider the five days of normal temperature and the lack of either local or constitutional symptoms—is easily explained. Owing to a disturbance in the domestic economy, the patient's room was at the time the only one in which he could be made comfortable, and thorough disinfection of the room while he was in it was impossible. In some way, perhaps on account of the tenderness of the skin of the foot, possibly—though the patient will not admit this—through some minute abrasion, produced by picking off the dead cuticle, germs entered from the air of the room and produced the second attack.

MEDICINE.

TWO CASES OF IMAGINARY POISONING.

Dr. Bernard Gordon, records in the *Medical Record*, the following cases:

Case I.—November 30, 1890, I was called to Mrs. S——; she was suffering from acute metritis, which was produced by the unskilful and rough manipulations of an ignorant midwife, who treated her for sterility. Having prescribed quinine for the fever, and having ordered hot vaginal injections with sublimate tablets, and the application of hot linseed poultices to the abdomen, I departed. The next morning I was called there to come immediately, the husband of Mrs. S—— poisoned himself with a tablet. On arriving I was surprised to find Mr. S—— without any symptoms of mecurial poisoning; he looked simply pale and frightened; but on inspecting the tablets, I understood that the druggist gave, instead of sublimate 7.3 gr., some other tablets. I went at once to the druggist, and found out that he dispensed hydronaphthol tablets, 1 grain in each; he was sorry for his mistake, but he blamed the apothecary in the neighborhood, who sold them to him also by mistake, instead of sublimate tablets. We can arrive at the following two conclusions: first, that Mr. S—— had extraordinary luck in escaping death, and second, that the druggists were very careless. I think this is the only useful error a druggist ever made, and therefore worthy of report.

Case II.—April 27, 1891, I was called in a special hurry to Mr. H——; his wife, I was told, poisoned herself. Arriving there I found Mrs. H—— fainting, being supported by her husband and servant. I examined at once her pulse and found it normal. I applied then a few drops of strong aqua ammoniæ on a handkerchief to her nose, and she opened her eyes, began to breathe deeply, and all at once became red in the face and started vomiting. I inquired what poison she took, but nobody except herself knew, and she did not answer. The husband meanwhile explained to me that his wife quarrelled with him at the dinner-table, and when he went away to his store she took some poison; he just arrived before me and gave her plenty of warm water to produce vomiting. "What poison did you take?" I inquired again of Mrs. H——, when she stopped vomiting after she had swallowed a few pieces of ice. "A teaspoonful of sulphur," she answered. I asked her how she came upon the idea of taking sulphur, and she explained to me, that she decided to poison herself by soaking matches in water and then drinking it, but being aware of the fact that matches are made of sulphur, she rather took sulphur, in order to end her life more quickly and without suffering. Blessed ignorance! If she had known a little more than that, the druggist might just as well have sold her five cents worth of phosphorus, instead of the sulphur.

THE RELATION OF URIC ACID TO GOUT.

Cammerer (*Deutsche med. Wochenschrift*, March 5, 1891) studies the advances made in the knowledge of the relation of uric acid and gout. He recognizes uric acid as a nitrogenous product from the albumen of the body with the formulæ of $C_5H_4N_4O_3$, produced not in the kidneys but in the liver; he regards it as an ultimate product,

not as a step in the process of urea-formation. It is distinguished from other constituents of the urine by its extreme insolubility. He prefers the silver method to the hydrochloric acid method in the determination of uric acid. Uric acid has been discovered in the blood of gouty persons, leucæmic cases and in the blood of birds. A thousandth of one per cent. can be detected by the silver method. Garrod found uric acid in the blood of patients suffering from lead poisoning as well as in gouty cases, from which he endeavored to create an analogy between the two conditions. The analyses reported by different observers vary most widely, being in many cases strongly contradictory, due undoubtedly to faulty methods of observation. Cammerer believes that these researches are much weakened by the omission of the estimation of the urea secretion and production. The conclusion is reached from the examination of the urine, that either gouty persons lay up a certain quantity of uric acid in the body, or the destruction of the albumen molecules results in the production of less uric acid than is produced normally. If the repeated examinations of the blood confirm the theory that there is an increased amount of uric acid in the blood of gouty persons it is due either to an evident increase of uric acid formation, as in birds and leucæmic cases, or it is due to an insufficient excretion of the manufactured product in the usual way. The first assertion has not yet been fully established; the other statement, as pointed out by Garrod, is sufficient to produce the diseased condition. This deficit may be so small that it cannot be detected; hence in these cases there is no violent change in metabolism and the gouty person may retain good digestive powers indefinitely. The relation of urea to uric acid in normal adults is about 100 to 2.8; in gouty persons, not under treatment, it averages about 100 to 3.1, hence the relative uric acid production and secretion are generally only slightly increased.—*Univ. Med. Mag.*

THE SENSORY AND MOTOR AFFECTIONS OF THE TONGUE.

MM. Du Pasquier and Marie have gathered together into an interesting paper the symptoms observable in the tongue, which contribute to the clinical evidence of nervous diseases, such as tabes, bulbar sclerosis, and others, and consider them under the three headings of sensation, motion, and nutrition. *Anæsthesia* of the tongue may be the result of local cerebral injury, of disease of the fifth nerve, or of hysteria; but from whichever cause it originates, it is almost always unilateral. It used to be considered as an almost diagnostic sign of hysteria, but more accurate knowledge of cerebral pathology has shown us that it may accompany motor weakness arising from injury of the occipital lobe, the optic thalamus, the posterior third of the internal capsule, the pons varolii and the external layer of the crus cerebri. In all cases except those originating from the pons the same side of the tongue is affected as of the body. In cases also of injury to the peripheral portion of the fifth nerve, such as by disease of the meninges or the bones of the skull, there is hemianæsthesia of the tongue. In hysteria it is much more frequent on the left side than the right; it may come on after some preliminary abnormal sensations of pricking or smarting, or sometimes suddenly after a hysterical attack without any knowledge on the part of the patient; and it lasts for a most indefinite time, short or long. *Hyperœsthesia* leading up to pain is the result of local disease of the tissues of the tongue, such as inflammation or cancer, or of neuralgia of the main trunk of the fifth, or more especially of the lingual nerve. In a few cases of tabes and general paralysis there are pains in the tongue associated with pains in the face; and now and then a feeling of great pain and tenderness in a limited spot, as if of an ulcer, but without any visible sign; an "imaginary ulcer," is preliminary to a general disease of the nervous system such as general paralysis (Verneuil, Fournier). Then with regard to the special sense of the tongue—*the sense of taste*, the different parts have somewhat different susceptibilities. The posterior part, which is innervated by the glosso-pharyngeal nerve chiefly, is the special seat of bitter tastes; the edges and point of the tongue, which are supplied by the lingual and the chorda tympani, are specially susceptible to the sweet and acid tastes. By the paths of these nerves the impressions of taste are carried to the grey matter of the occipital cortex along a somewhat uncertain course, probably through the middle of the thalamus opticus and the innermost fibres of the internal capsule; but they do not seem to reunite in any special cortical centre of taste. There is loss of taste more or less complete along with injuries of the glosso-pharyngeal, the trigeminus and the facial (acting through the chorda tympani). In a

well-known case of Pope's a thrombosis in the vertebral artery pressed upon the trigeminus, and so caused loss of taste on one side of the base of the tongue. Claude Bernard first showed that in cases of injury of the facial nerve the sense of taste is sometimes lost and sometimes retarded, whilst abnormal acid or metallic tastes are sometimes induced in the anterior two-thirds of the tongue. There is occasionally morbid exaltation or delicacy of taste in hysteria, hypochondriasis, catalepsy, and somnambulism. *Paralysis*, partial or complete, may be caused by injury of any part of the motor tract which may be traced upwards through the hypoglossal nerves to nuclei in the medulla, and from them by fibres running through the pons and internal capsule to a cortical centre. That the tongue alone should be affected by a cortical injury is a very rare accident, as in the case of a wound by a bullet recorded by Dugout and Bally (*Gaz. Méd.*, 1878, p. 23). There are a few cases in which symmetrical disease (hæmorrhage, softening, or tumor) of both hemispheres in the extra-ventricular nuclei has affected the motor tract of both sides of the tongue, and brought about a nearly complete paralysis with some likeness to the progressive bulbar paralysis of Duchenne, but differing from it in leading to no atrophy or loss of reflexes or loss of electric reaction in the muscles, and involving no laryngeal paralysis or cardiac and pulmonary disturbance. There is another group of cases, in which diseases of the spinal cord propagate their effects to the medulla, and thereby make themselves felt upon the tongue. This happens almost always in lateral amyotrophic sclerosis, cervical hypertrophic pachymeningitis, and disseminated sclerosis. In this last-named disease the slow, dragging character of the speech which results from the imperfection of the movements of the tongue is very marked. In locomotor ataxy there is often some hemi-atrophy of the tongue, but little impairment of speech; in hereditary ataxy (Friedreich's disease) there is much more constant difficulty of speech, leading quickly up to complete inability on the part of the patient to make himself intelligible. In facial paralysis the stylo-glossus is affected on the same side as the paralyzed muscles of the face, and the tongue turns towards the paralyzed side of the face; except in those few cases where facial paralysis has a cerebral origin, which is accompanied by paralysis of the genio-glossus and a turning of the tongue away from the paralyzed side of the face. From the local paralysis which accompany the use of lead and mercury the tongue is remarkably exempt, but it is occasionally affected by the weakness or inco-ordination which follows acute fevers, more especially enteric.—(*Le Progres Médical*, pp. 107, 123, Feb. 7, 14, 1891.)

A NEW CONTRIBUTION TO OUR KNOWLEDGE OF REFLEXES.

Erb (*Wiener Med. Wochenschr.*, 1890, p. 879) has contributed an important paper on this subject. He first discusses how far the anterior cornual cells of the spinal cord are concerned in the production of a tendon reflex, and he points out that many of the cells may be totally destroyed and yet the tendon reflexes will remain perfect for the rest of life, and he does not regard it as a satisfactory explanation that the remaining cells take on the function of those which are destroyed. Further, he argues that in many cases in which the loss of the reflexes has been attributed to destruction of the cells of the spinal cord the anterior nerve roots have been severely damaged, and in progressive muscular atrophy the loss of the reflex does not take place until there is considerable change in the muscle itself. Erb next refers to the clinical fact that, after hemiplegia with secondary degeneration, there is often an increase of the tendon reflexes on the non-paralysed side; this most authors have been accustomed to refer to an increase in the irritability of the reflex centres on the unparalysed side, consequent upon their physiological association with those on the paralysed side. Erb considers this hypothesis unnecessary now it is known that descending degeneration takes place on both sides of the cord. Lastly, he does not consider that in the explanations of the alterations of tendon reflexes after apoplexy, sufficient allowance has been made for the alterations produced in the surrounding parts of the brain by the vascular disturbances which must be associated with a large hæmorrhage.—*Brit. Med. Jour.*

HISTOLOGY OF ACNE VARIOLIFORMIS.

Dr. Bronson (*Jour. of Cut. and Genito-Urin. Dis.*, April, 1891,) publishes the results of a microscopic examination in a case of acne varioliformis, which seems to show that the lesion begins as a deep-seated small-cell infiltration about the coil glands, which are situated beneath the hair follicles. In the beginning several independent foci of inflammation are present, which subsequently

coalesce, producing a generalized infiltration of the derma with a tendency to central degeneration. As the infiltration approaches the surface it penetrates and disintegrates the overlying epidermis, separating it from the adjacent tissue. The central dry necrotic mass which represents the final stage in the evolution of the pathological process is made up of the epidermis with the underlying tissues of the derma, which have undergone a peculiar degeneration, and have become separated from the adjoining tissue by a sharp line of demarcation. The examination, unfortunately, gives little insight into the nature and cause of this singular affection, nor does it reveal why the affected tissues should be thrown of *en masse* rather than undergo a liquefactive degeneration. One would be led to suppose, however, that some agent, bacterial or chemical, had played an active part in the inflammation, causing a reaction on the part of the tissue and an endeavor to throw off the offending cause and its results. The formation of pus, which is not a constant feature of the papules, was doubtless due to a secondary infection by pus cocci.—*Brit. Med. Jour.*

SURGERY.

A NEW METHOD OF PERFORMING JOBERT'S OPERATION.

Dr. Fred. B. Robinson, in the *Annals of Surgery*, says that the present modification of Jobert's operation is with the hope of improving the safety of the operation. The danger of Jobert's operation proved very great in our experiments, and of course, the main danger lies in the occurrence of fæcal fistula at the points of the invagination sutures. The modifications or improvements he has to offer on Jobert's operation are: First, the avoidance of the invagination sutures, and second, the use of a rubber tube to keep the bowel from invagination at the seat of operation; and third, to keep the lumen of the bowel patent at the same point. The invagination in Jobert's operation produced fæcal fistula (with both catgut and linen sutures,) and also caused death. The idea that invagination of the intestine will continue to a point of obstruction, from simply turning in a small part of its end, to do the operation, he never saw recorded, but it will actually happen, and it killed several of our dogs. Hence, to avoid this disaster, an operation should only turn in about one-half to three-fourths of an inch of the end of the gut. The muscles from that short bit of gut can not get purchase power to progress. In closing a gut end, only one-half an inch should be turned in, and then sutured with a few continuous Lembert sutures. The addition of a rubber tube, he thinks, increases the safety of the operation very much.

The rubber tube certainly aids in preventing subsequent invagination at the seat of the operation, and the longest part of the tube should be above (three-fourths) the point of operation. The tube keeps the gut lumen patent. It holds the two serous surfaces, which are to unite, in constant approximation. It prevents the gut from wrinkling and allowing fæcal extravasation. It produces the great essential of healing, which is mechanical and physiological rest, which, alone, induces appropriate cell proliferation. The tube is held in its position by one or two sutures passed through the edge of the proximal intestinal end and through the tube. One can determine how long the tube will remain in position by the amount of intestinal wall, the suture, which holds the tube, embraces; or on the kind of sutures (catgut or silk or linen).

The main steps of the operation are the severing of the gut and the determination of the proximal and distant bowel, or the direction of the fæcal current. The serous surface of the distal gut is scarified for one-half inch and invaginated to the same extent. Now, a rubber tube which snugly fits the gut lumen is pushed up into the proximal gut and stitched there, (he generally used a tube five inches long, placing about three inches above and two inches below the point of operation.) An inch of the serous surface of the end of the proximal gut is scarified. Then the proximal gut is inserted into the invaginated distal bowel for one inch. A circular row of Lembert sutures are applied at the junction of the serous surface of the proximal and distal bowel.

The same surface for one-half inch adjacent to the sutures is well scarified, and an omental graft wrapped around and sutured in position. The omentum is carefully respread over the intestines, and the belly closed.

The avoidance of the invagination sutures is a great step in advance. The addition of the rubber tube and scarification, with an omental graft, add infinitely to the chance of recovery. Of course, Jobert's operation, and this modification of it, is only to get something better than the dangerous circular enterorrhaphy. Circular enterorrhaphy was found, in the experiments, to show

very clearly the following dangers, which he has previously noted, but which he repeats in order that attention may be directed more to them:

1. Circular enterorrhaphy paralyzes the gut at the seat of operation, and hence does not so readily relieve the fæcal obstruction, which is the immediate object of surgical interference.

2. Fæcal fistula is apt to arise at the point of the operation.

3. Gangrene or sloughing may arise from the pressure on the tissues of numerous sutures.

4. The lumen of each gut may not be of the same size, and thus present difficulty in union.

5. The pathological changes in the bowel, due to obstruction, offer impediments. The gut may be stretched so thin that a needle can not be passed between the muscular layer and mucous layer without danger of penetrating the mucous membrane and causing fæcal fistula. Also the stretching of the bowel may seriously impair the power of healing. The trauma has destroyed the vascular and nervous integrity of the tissues of the gut wall.

EPISTAXIS.

In a recent paper read before the Southwestern Ohio Medical Society Dr. T. V. Fitzgerald said that the successful management of a severe case of epistaxis depended in a great degree upon a correct diagnosis of the lesion essential to the existence of the hæmorrhage. A correct diagnosis can not be made without the use of reflected light and the nasal speculum, and indeed, such of the armamentarium as are used in making a careful and thorough examination of the nasal cavities. In making a diagnosis it must be borne in mind that epistaxis is a symptom of an intra-nasal lesion. Slight attacks may be passed by with little regard, unless frequent, when, if for no other purpose, than to relieve by appropriate treatment the intra-nasal lesion, a careful examination should be made. The number of remedies used to arrest nose bleed, and most of which are useful at least in mild cases, are legion. It is not the purpose of this paper to discuss the merits of all the remedies thus used, but rather to emphasize the method of applying them. Such remedies as plunging the hands and feet in water as hot as can be borne, or applying cold water, or the ice pack to the forehead, face or back of the neck, do very well when the hæmorrhage is largely due to increased blood pressure plus intra-nasal lesions, but when we have erosions of the septum nares, or even slight excavation, such remedies are utterly incapable of arresting the hæmorrhage. If the bleeding point has been located, and the nasal mucus membrane been thoroughly anæsthatised with cocaine, there is no more trustworthy remedy than water as hot as can be borne. Having the sensibility of the nasal mucus membrane deadened you can use the water at a very high degree of temperature; if it is not used at a very high degree it is not hæmostatic. The writer has never failed to promptly arrest the severest case of epistaxis that came within his care by the use of this simple remedy. The application of pledgets of iodoform gauze to the bleeding points, or in case of diffuse hæmorrhage, will in many cases act promptly. It would be well to always apply the gauze after the hæmorrhage has been arrested by the use of hot water in order to maintain as near an aseptic condition as possible. Tamponing the nose is a remedy the use of which is to be greatly depreciated and should never be resorted to unless all other remedies have utterly failed. It is the most painful method of treating epistaxis, the suffering lasting several days. The pent up blood and secretions affording excellent material for cultures of pathogenic germs. Prof. Gross reports several deaths from septicæmia from its use. Other writers have reported cases of erysipelas, fatal tetanus, inflammation of the eustachian tube, abscess of the middle ear, etc. The necessity of using the tampon will indeed be rare if the application of less painful and less dangerous remedies as hot water, iodoform gauze, lemon juice, tannic and gallic acids be thoroughly made to the bleeding point.

GASTROSTOMY IN CANCER OF THE ŒSOPHAGUS.

In some clinical comments on five original records of gastrostomy performed in cases of cancer of the œsophagus (*Revue de Chirurgie*, April, 1891), MM. Terrier and Louis, of the Hospital Bichat, Paris, advocate this plan of treatment, the frequently fatal results of which, it is held, are due more to the enfeebled condition of the patient than to any risks attending the operation itself. The authors consider how certain inconvenient results which have been observed in cases of recovery may be prevented by improved methods of operating, and sum up their views in the following conclusions:—(1) Gastrostomy in cases of cancer of the œsophagus is decidedly a justifiable palliative operation,

and ought to be proposed to the patient; (2) its performance is very simple, and the immediate results are not attended with much gravity; (3) the ulterior evils due to the presence of a gastro-cutaneous fistula may be avoided by opening the stomach as near as possible to the superior curvature, by making only a small orifice, and by dispensing with the subsequent use of occluding agents; (4) then simple dressings only will be needed, and these should consist of inert powders, or of such (carbonate of magnesia, for instance) as are capable of neutralizing any drops of gastric fluid that might be discharged during any forcible effort made by the patient; (5) the results of gastrostomy with regard to the survival of the patient are influenced by the duration of the disease and the extent to which the stomach is involved. Certainly in France, intervention, as a rule, is too late, and the chances of survival are consequently much diminished.—*British Medical Journal.*

SUCCESSFUL TREPHINING FOR TRAUMATIC RUPTURE OF THE MIDDLE MENINGEAL ARTERY.

In the *Gazette hebdomadaire de mêdecine et de chirurgie* for December 27, 1890, there is a report by Dr. Rochet of the following very interesting case: A man, aged twenty-eight, was thrown violently to the ground, striking upon the right parietal protuberance; he was carried, unconscious, to a house, where he remained for some twenty-four hours before being removed to a Hospital. He was then like a person in a deep sleep, though when interrogated he would open his eyes but make no other response; there was ecchymosis of both eyelids, of the zygomatic region, and of the temporal fossa, but none of the conjunctivæ, with swelling of the entire ecchymosed region of the right side. Pressure over this region produced pain sufficiently severe to rouse the patient from his torpor and produce grimaces. There was no injury to the integument, and there was no hæmorrhage or serious discharge from the ears or the nasal fossæ. There was neither paralysis of the face or extremities nor incontinence of urine or fæces. But on the third day after the accident facial paralysis began, with conjugate deviation of the eyes; the left arm was completely, and the left thigh and leg were partially, paralyzed; cutaneous sensibility had diminished; the right pupil was widely dilated; and the right cornea was almost absolutely insensible. On the fourth day, if he was asked where and how he suffered, he constantly indicated the right side of his head; during that night he was agitated, crying at times, at others attempting to rise. He remained in the condition noted on the third day for five days, when surgical intervention was decided upon. The operation was begun, after the usual antiseptic preliminaries, with a crucial incision over the right fissure of Rolando, and on throwing back the flaps a long line of fracture was seen crossing the parietal bone. A trephine was applied where this line crossed the line of the fissure, and on removing the bone button there was a jet of black blood; this ceased spontaneously, disclosing a black clot at the orifice. The orifice was enlarged with a gouge and mallet to from 6 to 7 centimeters in length, by from 2 to 2.5 centimeters in width. There was clot in all this region; that was removed carefully with the finger and curette, disclosing a cavity as large as an orange occupying all the temporo-parieto-occipital region and limited externally by the cranium and internally by the flattened right hemisphere. While the last of the clot was being removed there was a jet of arterial blood that stopped this work. The cavity was washed with boric-acid solution and gently packed with iodoform gauze; no sutures were taken in the scalp; the external wound was dressed with sterilized cotton. During the evening of the day of the operation the patient recovered his consciousness, and the hemiplegia was greatly improved. The wound was dressed on the day after the operation; the cavity had decreased in size, there were some clots, and the hemisphere pulsated. On the succeeding day the facial paralysis disappeared, though the tongue still deviated slightly. The patient progressed satisfactorily to recovery, the only lingering symptoms being an awkwardness of the left arm and occasional vertiginous sensations.—*N. Y. Med. Jour.*

VENESECTION AGAIN.

Venesection tries very hard to get upon its feet again. Every now and then we come across an article or a discussion in which this ancient therapeutical stand-by is petted and praised and coddled; but after this comes silence again. The pride and staff of our forefathers seems to remain in hopeless senility. Phlebotomy does not get popular. Medical fashions, we are told, run their course, and after a time re-appear. Calomel has been taken up again, and perhaps as many people take mercury now as ever, though in more modest doses. But the modern doctor still will not bleed.

At a recent meeting of the Royal Medical and Chirurgical Society, Dr. Pye-Smith told us again how useful venesection is. He reports fifty cases! Half a century ago every country doctor could report as many in a year. Dr. Smith thought venesection indicated in cyanosis with distention of the right side of the heart, whether from pulmonary or from some other obstruction to the circulation; in the intense pain of thoracic aneurism; and in uræmic and prolonged epileptic convulsions. Dr. Stephen Makenzie and Dr. Broadbent confirmed the views of Dr. Smith. With such authorities, perhaps, there will be a little more phlebotomy, at least in our Hospitals. But its use in private practice will be limited for a long time to come.—*Med. Rec.*

THE EMPLOYMENT OF ANILINE COLORS AS ANTISEPTICS.

Stilling (*Rev. gên. d'ophthal.*, April 30, 1890) has convinced himself that wounds and suppurating ulcers in and about the eye, treated with aniline, may be entirely sterilized by the solution penetrating everywhere, and the suppuration may be entirely arrested. When the pus is deep in the tissues, injections of the aniline solution should be employed, or the introduction of aniline crayons, or bathing with concentrated solutions. In many cases application of a powdered aniline is very efficacious. He has employed several of the methyl violets and one auramine. These aniline colors are destitute of all toxic action; they are very diffusible, and they do not coagulate albumen. It should not be forgotten that solutions of these aniline colors are soon decomposed by exposure to light, and they should therefore be kept protected.

GYNÆCOLOGY.

MENTAL ABERRATION DURING MENSTRUATION.

The following interesting study of the nervous derangements superinduced by erratic or disordered menstruation, is an extract from a paper read by Dr. Robert Barnes, the eminent English gynæcologist, at the opening meeting of the British Gynæcological Society:

"The phenomena accompanying the menstrual period are very numerous, and for the most part of a congestive nature, affecting various organs. In many cases the attack is entirely borne by the nervous system. This is the explanation of the periodical and temporary disturbances at the catamenial epoch. A young girl of nineteen, born of neurotic parents, of good general health, came into the hospital on account of trouble of this nature. Her menses had been regular, but at each return she became subject to spasms of asthma, and at the same time suffered from very severe uterine colic. Six months previously, in consequence of violent emotion, the menstrual period was suddenly arrested, and a state of insanity with hallucinations came on and continued for ten days. The mental disorder then completely disappeared, only, however, to be renewed at the next monthly epoch, and from that time the condition has been renewed at each corresponding period. The alienation is particularly characterized by an excessive loquacity, by agitation, partial vision, etc. There were no aggressive symptoms. An attack always lasted from eight to ten days, after which she became sane, but retained no recollection of her madness. Now, this is an important point; for a maniac who remembers nothing of his attack is much farther removed from cure than one who remembers its incidents, and can speak of them, especially if he can do so without blushing. In this patient there is an absolute coincidence between the menstrual period and the manifestation of insanity. The former pains, too, have completely disappeared, as if they had been a sort of counterbalance to the cerebral excitement. The origin of these attacks is to be found in a predisposition. Her father was subject to attacks of melancholia, and her mother was of a neuropathic constitution. A sister was a hystero-epileptic, while as to herself, she had been under an extreme mental strain at the time of the first outbreak.

"Most women experience during menstruation some morbid manifestation which is generally related to the nervous system. The most common disorder is migraine, which may be looked upon as the beginning of a slight cerebral excitation. But, besides this trouble, which is so common, eccentricities of character are sometimes developed, and may attain an extreme degree. In the hysterical, and especially the epileptic, attacks are often excited at this time. The most frequent mental disturbance takes the form of a modification of the natural disposition, which becomes quarrelsome and contradictory, and renders the patient a torment to the household. Terrible fits of jealousy are also often produced. In these the normal and intellectual disturbances

only hint at graver results. But numerous observations testify to the development of dipsomania, kleptomania, etc. Erotomania, likewise, is of frequent occurrence, and a case is on record in which the patient, in a state of extraordinary genital excitement, demanded to be led to a house of prostitution.

"The most serious of all these troubles is homicidal mania, of which a certain number of well-attested cases are known. Usually, however, the mania is generalized. It is mania properly so-called, and rages during the flux of blood. All these complications usually cease with or soon after the menstrual period. But occasionally, the victims become chronic maniacs. Melancholia is generally the form which the alienation assumes. This is especially seen in young girls at the appearance of the first menstruation. The perversions may afterward disappear.

"The prognosis of menstrual insanity is, indeed, comparatively favorable. It is necessary, however, to take into consideration a predisposition. With this exception, therapeusis is more effective than in other forms of insanity. Leeching and blistering may be of some use, but the principal reliance is to be placed upon the bromide of potassium, which is essentially a genital remedy. It is well to employ it in all the milder varieties of the disorder, which are always physiological, but which, nevertheless, are not without importance. Finally, when actual insanity is concerned, we must not forget that opium, morphine, atropine, and small doses of tartar emetic are very efficacious sedatives."—*St. Louis Cliniques.*

THE CURE OF UTERINE HÆMORRHAGE.

It is a very good working maxim for practical gynæcologists that when a woman suffers from uterine hæmorrhage the first thing to do is to explore the cavity of the uterus, dilating the cervix if necessary. There are plenty of cases on record in which one or other of the so-called "radical" operations has been performed where subsequent post-operative evidence has been afforded of the fact that the hæmorrhage might have been relieved by a much more simple and less dangerous procedure. For instance, a patient with multiple fibroids of the uterus floods repeatedly. The condition of the uterus having been diagnosed it is either removed *en bloc* or the tubes and their appurtenances are snipped off. Subsequently it is ascertained that the hæmorrhage was due to an undiagnosed, because unlooked-for, polypus of the uterus, and then both the operator and the patient are left to repent at leisure. Like every other rule, however, this one is subject to exceptions, but as these are exclusively of the mechanical order they only confirm the rule. We do not require to be told by a surgical luminary that when exploration of the uterus is for any reason impossible, that it should not be employed. It is evident that if the conditions be such as to forbid dilatation of the cervix, then it may be the duty of the surgeon to neglect this otherwise indispensable preliminary measure and proceed at once to the major operation, on the basis that the whole includes the part. Hysterectomy is a somewhat more serious operation than pulling out a tooth, but when it alone offers a chance of rescuing the patient from an exsanguineous grave, it must first be resorted to. There can be no two opinions as to the theoretical course to pursue, but, judging from the discussions at societies, there seems to be very considerable difference in practice.—*Med. Press.*

A HISTORY SHOWING THE HARM ELECTRICITY MAY DO IN UNSUITABLE CASES.

Dr. Skene Keith, in the *Edinburgh Med. Jour.* says:

It is a strange trait in human nature, that, whenever a new idea is brought forward it is, at first, either made too little or too much off. This has been the fate of Dr. Apostoli's method of the use of electricity in the treatment of disease; and the history of the following case is but one example of the harm which may result from the use of electricity in unsuitable cases. The value of this treatment in the symptomatic cure of fibroid tumors of the uterus is, in my opinion, a settled fact, though it is not yet accepted in conservative medical centres, like London and Paris; and if the inexpert would only stick to what is definitely known, and not begin experimenting on their own account, the unfortunate result to be recorded need not have happened.

In the month of August 1888, I saw a patient from the west of Scotland, 39 years of age, who had been suffering for almost three years from pain in both groins, down the legs, and in the back—all these symptoms being aggravated at the time of the monthly period. She had never been pregnant, and no history was obtainable as to the origin or commencement of the pains. The

general health was not in any way affected, and there did not appear to be very much suffering. On examination, the uterus was felt to be fairly normal, and on either side was found a rounded mass, presumably enlarged ovaries with more or less disease of the tubes.

Those swellings were somewhat moveable, and there did not appear to be many, if any, adhesions. Removal of the ovaries and tubes was therefore advised, if the patient thought herself ill enough to submit to an operation. This was at once declined, and the patient asked if electricity would not do her good. She was assured it would not cure her; and she was told that I believed that it would not only be of no service in her case, but would probably do more or less harm. Nothing was heard of her for nearly two years. She then came back looking a complete wreck. Until six months before, she had continued in much the same condition as when first seen. Then, still full of the idea that electricity would cure her, she sought further advice, and got the electricity she was so keen about. How it was administered I do not know; but that something must have been wrong is evident, from the fact that the applications caused very great pain, and sometimes, the patient stated, the sound was not passed into the uterus. The result is best described in her own words—"I thought that I had been ill for five years; but now I know that I have only been ill for six months."

Examination revealed a great change. The uterus, instead of being movable, was pushed up against the pubes by a tense swelling, which filled the whole of the pelvis and projected into the abdomen. A diagnosis of abscess of the ovary or Fallopian tube was made, partly from the examination, and partly because the patient had frequently feelings of chill and slight rigors; the pulse was quick, 120, and she looked like one with pus somewhere. Operation was now insisted on; it had ceased to be a matter for the patient to decide. Although it was explained that she ran great risk, she now at once consented; she was thankful to have the chance of relief offered by operation.

The operation was performed in June 1890. All of the pelvic tissues were matted together, and, in addition, the broad ligament was open up to below the level of the cervix. Two accidents occurred,—first I ruptured the sac when the enucleation was almost finished, the putrid pus at once filling the pelvis; and then, in separating adhesions deep down in the pelvis, I opened the bladder.

This would probable not have happened had the sac remained intact, but the matter together with all the pelvic structures was so dense, that when the sac was flaccid it was extremely difficult to make out its relations, and the bladder tore like a piece of wet blotting paper. There was thus a great mess to clean up, and this was done by washing out with warm water. It has not been necessary for me to do this as often as once in over seventy cases, three times in all; and it is more than doubtful if the method is necessary for the expert operator, who is, at the same time, careful. Naturally, one must wash out if there has been a rupture before operation, and putrid matter has been able to reach the peritoneal cavity, as happened in a case of ovariotomy performed by Dr. Keith last year, where a suppuration dermoid had ruptured twenty hours before operation. In such a case, washing out may fairly be said to have saved the patient's life; but it is only, in my opinion, in a case of this nature, or where the peritoneum has been infected at the time of operation, that it is of use. Washing out seems to be often used without judgment, and I see that Mr. Thornton seems to agree with me that it is not often necessary.

The bladder opening was sewn up with fine silk, and after the right ovary had been removed and a number of bleeding vessels tied, the wound was closed, a drainage-tube being left in. The patient was put back to bed after an hour's operation with a wretched, shabby pulse of 144.

On examining the specimen it was impossible to say whether the original site of the disease had been in the ovary or tube. From the time the patient was put back to bed until her death at the end of sixty hours, there was not any sign of improvement. The pulse became quicker and quicker; and she died simply from the injury inflicted on a woman in a greatly debilitated state of health. There were not any abdominal symptoms; no distension nor sickness, and the urine which was drawn off every two hours was abundant. It is interesting to note how anxious the patient was to avoid any mutilation until it became absolutely necessary for her to do so, and then only consented with the hope of saving her life.

For winter cough of the aged—pure terebene, ten drops on sugar, or in emulsion with other remedies as indicated, is good treatment.

OBSTETRICS.

METRORRHAGIA: SHOULD THIRST BE QUENCHED?

G. Jorissenne, M. D. (*Archives de Tocologie,*) combats the principle of allowing plenty of drinking water to patients exhausted by flooding, whether after labor or in fibroid disease. The practice is advocated on physical and therapeutic grounds. Yet its defenders admit that there is diminution of the plasticity of the blood in these cases, and administer steel and other remedies in order to increase that plasticity. The absorption of quantities of water into the circulation must have the opposite effect. Dr. Jorissenne maintains that the patient should not be permitted to drink freely. Slices of sugared lemon or acidulated drops should be administered in order to quench thirst. The patient, he adds, should be kept in the recumbent posture, with the arms raised; from time to time ammonia may be inhaled. This treatment is especially advisable in women subject to deficiency of colored blood corpuscles. Eighteen years ago Dr. Jorissenne tried his line of treatment on a woman of fifty-three, who was dying from hæmorrhage after abortion at the third month. She was a stout, anæmic multipara, of violent temper. There was difficulty in removing the placenta, and both plugging and astringent intra-uterine injections failed to check the bleeding. The patient fell into a desperate condition. Dr. Jorissenne noticed that she was continually drinking tumblerfuls of cold water. Considering that the source of hæmorrhage was being fed, he strictly forbade all drinks, raised the arms, rubbed the lips with vinegar and lime-juice, gave the patient ammonia to inhale, and plugged the uterus again. No drink was allowed for three hours. The patient then rallied and recovered, and is now alive, a healthy old woman. He was successful in two other cases of flooding; one after abortion, between the second and third month; the second after a lingering labor, mismanaged by an ignorant midwife. These cases were less serious than that above described, but Dr. Jorissenne was able to commence his treatment much earlier. He admits that in very plethoric patients this dry treatment of flooding might be harmful if too rigidly enforced.—*Archives of Gyn.*

ACUTE TORSION OF OVARIAN PEDICLE.

Dr. Mackenrodt (*Centralb. f. Gynäk.,* March 28th, 1891) describes the case of a patient, aged 38, who had been seized on December 16th, 1890, with sudden increase of abdominal pain, from which she had suffered for years. Her abdomen had recently grown larger. On December 17th fæcal vomiting came on, and became frequent on the next day; neither fæces nor flatus passed from the anus. On the 20th, when she was admitted into Dr. Martin's institution in Berlin, she was collapsed and jaundiced; the temperature was normal, the pulse small and frequent. The uterus was pressed against the symphysis by a tumor which reached to above the naval. The abdomen was distended and tender. The legs and abdominal integuments were œdematous. On December 21st abdominal section was performed. A deeply congested ovarian tumor, strangulated by torsion of its pedicle, was found and removed. The entire surface of the peritoneum in the hypogastric and pelvic regions was dark blue from congestion. As there were no adhesions the operation was not difficult. The pedicle, about 2 inches broad, was twisted one turn and a half around its axis. Recovery was rapid. It is remarkable that, notwithstanding the severe symptoms of strangulation and peritonitis, there was no rise in temperature, yet the pulse was much affected. The tumor was a dermoid ovarian cyst; and free hæmorrhage into its cavity had occurred.—*Brit. Med. Jour.*

VELAMENTOUS INSERTION OF THE CORD.

Dr. Addison Foster (*American Journal of Obstet.,* April, 1891) read notes of a case of this complication before a recent meeting of the Gynæcological Society of Chicago. The patient, aged 26, had a lingering and painful but otherwise natural labor. The child was delivered with considerable flooding, and was blanched. The flooding continued till the expulsion of the placenta, which took place without any difficulty. The umbilical cord entered the membranes opposite the placenta, and, dividing and spreading, passed to the edge of that structure, where it divided still more into branches, which ran over the placental surface. One large vein, about 4 inches from the margin of the placenta, was ruptured. Dr. Foster believed that it was the seat of hæmorrhage. Dr. Jaggard, in discussing this specimen, pointed out that the case was typical; the cord was inserted into the chorion at the pole of the ovum opposite to the placenta. The anomaly did not appear to affect the development of the child or the course of the labor.—*Brit. Med. Jour.*

PÆDIATRICS.

EXTENSIVE POST-DIPHTHERITIC PARALYSIS.

Drs. Torras and Passual, in the *Siglo Medico*, August 10, 1890, report the following case of extensive post-diphtheritic paralysis:

A child, male, 4½ years old, which, from the statements of the mother, undoubtedly had passed through an attack of laryngeal diphtheria, presented itself at the Hospital. There was paralysis of the velum paliti; the voice was nasal; food and liquids were regurgitated through the nose. The lower limbs were paralyzed; their muscles were paralytic and flaccid, and the child was unable to stand. Syrup of proto-iodide of iron was prescribed, and as nourishing food as possible ordered to be given, and the mother was told that the symptoms would disappear gradually in the course of a few weeks. But this prognosis, instead of being confirmed, was followed by the development of a grave bronchitis, pointing to an affection of the bronchial muscle-fibres. The patient coughed, and could only with difficulty raise the profuse sputa. An expectorant was prescribed, and as constipation had been existing for two days, which would seem to indicate an implication of the muscular tunic of the intestines, an infusion of senna was administered, and a rectal injection of soap and water was ordered. This caused the expulsion of several fæcal masses and a diminution in the size of the distended abdomen. As the lung symptoms diminished in severity, tincture of nux vomica, in combination with ergotine, was given in increasing doses. After continuing these remedies for several days, the motility of the affected muscles returned; the thoracic and abdominal symptoms also disappeared quite promptly; the child's appetite improved, and in ten or twelve days he was able to stand. The voice lost its nasal sound; deglutition became easy and quite normal. The remedies were continued for some time after the disappearance of all the symptoms. The writers would regard mux vomica and ergotine as powerful agents in such conditions.— *Jour. Nerv. Ment. Dis.*

DRAINAGE OF THE VENTRICLES OF THE BRAIN FOR HYDROCEPHALUS.

Dr. Brocas reports two cases of chronic hydrocephalus treated by this procedure. In the first one Dr. Thiriar, of Brussels, performed trephining, with puncture of the ventricle and drainage. Death occurred on the sixth day. The second case which was operated upon by Dr. Brocas was that of a boy, three years of age, who had suffered from convulsions since the seventh month. The attacks increased in frequency and were attended with an increase of volume of the head. A year ago right hemiplegia developed after a severe attack. The right upper extremity was in a position of flexion, the fingers could not be moved; this condition gradually improved, although the right hand remained stiff. Eight months later, three months before operation, convulsions again occurred, and were followed by hemiplegia of the left side. The condition of the affected lower extremity improved, but a contracture of the upper extremity persisted. After puncture of the ventricles and drainage the contracture disappeared completely, and the child recovered promptly.—*Wiener Medizin Wochenschr.*, No. 16, 1891.

FŒTAL ENDOCARDITIS.

Drs. Porak and Bernheim (*Bull. et Mém. de la Soc. Obstét. et Gynéc de Paris*, No. 4, April, 1891) exhibited specimens illustrating fœtal endocarditis. A fine male child, the third that its mother had borne, was safely delivered at term. Three days after birth it became jaundiced. On the fourth day it was occasionally cyanosed, but nothing could be detected on auscultation. On the fifth there was dyspnœa, with dullness over different parts of the lungs, and moist *rales*. Next day the infant died. Large areas of red hepatisation were found in both lungs. The left ventricle was found extensively diseased, the mitral valve destroyed by endocarditis, the aortic valves thinned and fused, so that they formed a simple diaphragm with a central aperture. The aortic orifice and the aorta itself were narrow. The foramen ovale was patent, and allowed of a certain amount of compensation, nevertheless the obstruction to circulation was great, as the frequent, though intermittent, cyanosis proved. The hepatisation of the lungs was attributed to the impairment of the functions of the left heart, and the dilatation of the right chambers (otherwise normal) was the result of the obstruction to the pulmonary circulation caused by the disease on the left side. Haranger has distinguished three varieties of right endocarditis in the fœtus. In the first form the aortic orifice becomes closed; in the second it is not so affected; and in the third the endocarditis is confined to the mitral valve.—*Brit. Med. Jour.*

HYGIENE.

AN EARLY PROOF OF THE VALUE OF VACCINATION.

A correspondent of the *British Medical Journal* sends to it the following extract from a French newspaper of October 3, 1804: "Six black children, the first who had ever been vaccinated at the island of Réunion, and from whom 5,000 people were vaccinated, were shipped on board the vessel Jeune Caroline, bound for one of the Seychelles Islands to perform quarantine for small-pox. The six children were three months on board the ship, eating, drinking, and sleeping with the sick; during the time of quarantine they were inoculated with the virus taken from the pustules of the diseased passengers, by large incisions made on both arms. From the report made at the time and communicated to the Central Society of Vaccine by the Minister of the Home Department, it was found that, although these six children had slept under the same blankets, and in contact with the pustules of the sick, eating and drinking out of the same vessels, and having been inoculated with pus from the patients who ultimately died of the disease, they were all preserved from the contagion, and were during the whole time in perfect health. The proof and counter-proof is one of the most severe tests ever performed, and ought to have a marked place in the history of vaccination. The fact of six children having lived in perfect health on board a small ship infected with small-pox, having on board twenty blacks with confluent small-pox—six of whom died—twenty to twenty-five others with dry crusts all over the body, with seven deaths before their arrival at the quarantine station, all packed in a small space between decks, is perhaps the most crucial test ever witnessed of preservation by vaccination."

MILK AND DIPHTHERIA.

E. Klein (*Nineteenth Annual Report of the Local Government Board*, 1889–90, p. 167) inoculated two milch cows (both of which had calved three or four weeks, and then had been kept under observation for a week or ten days) with a broth culture of the bacillus diphtheria derived directly from human diphtheria membrane, which had been incubated for three days at 37° C. On the third day he found at the seat of inoculation (under the skin of the left shoulder) a swelling containing clear sanguineous serum; this was preceded by a temporary rise of temperature. On the fourth day a small group of vesicles occurred on one teat, and on the udder near to it. On the succeeding days these vesicles lost the clear vesicular appearance, became purulent, and the centre became dark, whilst at other stages they were covered with brown crusts. Around each was distinct nodular induration of the skin, and each was placed on a raised injected corium. On removal of the crusts an ulcer covered with a purulent film was left. The pustules and ulcers varied in size from $\frac{1}{8}$ inch to $\frac{1}{2}$ inch or more in diameter; most of them were on the udder between the hind teats, but some were on the outer surface of the udder near to the base of the teats; they still continued to appear on the eighth day. The most marked feature about these was that they ran their course in from six to eight days. In the lymph of these vesicles and pustules Klein succeeded in demonstrating the bacillus diphtheria, both under the microscope and in the culture tube. With milk taken from these cows cultures were also obtained, though not in large numbers. If the milk was allowed to stand at a temperature of from 19° to 20° C. the organism was found in enormously increased numbers. One of the cows died on the fifteenth day, the other was killed on the twenty-fourth, when marked *post-mortem* changes were found: necrosis and œdema at the point of inoculation, enlargement of the lymph glands, pneumonia, enlarged spleen, necrotic patches in the liver, and fatty degenerative changes in the kidney. Organisms were found only at the point of inoculation. Calves inoculated with scrapings of the eruption of the cow developed similar symptoms, but no vesicles were formed. Cats fed on milk from the affected cows died with typical diphtheria, and communicated the disease to other cats placed in the same room, typical diphtheria bacilli being found in the diphtheritic membranes of these animals. The last experiment was not specially arranged, and thus loses and gains in value as it is considered from different points.—*Brit. Med. Jour.*

MICRO-ORGANISMS OF YELLOW FEVER.

Professor Domingo Freire, of Rio de Janeiro (*Deutsch. med. Woch.*, No. 17, 1891), maintains that there can be little doubt that bacteria play a most important part in the causation of certain specific diseases, but that along with bacteria there are accessory factors that must always be taken into

account. In yellow fever, which is undoubtedly of bacterial origin, we have an admirable example of the necessity that there is for the presence of the various factors for the production of the disease. It is a disease which is found only in hot climates, and there only in patients who, from altered conditions of the gastric juice and blood or tissue juices, offer suitable media in which the specific organisms can flourish. The organism found in yellow fever is rounded, single, or in little masses of chains; it is usually stained with fuchsine, methyl violet, and cherry red; it grows readily in peptonized agar, beef-jelly, and broth—on the agar especially, prominent growth appearing on the surface. The colonies, at first white, become yellow, then grey, and even black; the organism separates out two distinct pigments, one of them yellow, soluble, and easily diffusible into the tissues, giving rise to the characteristic color to which the disease owes its name; the other black, insoluble, and very frequently met with in vomited matter (black vomit). Toxic ptomaines may be separated from cultures, and these, when injected into frogs and rabbits, produce typical bulbar symptoms, the poison acting especially on the sympathetic and pneumo-gastric nerves. Injections of blood from a yellow fever patient, or of pure cultures of the organism, produce all the characteristic symptoms of the disease in guinea pigs. Professor Freire, as is well known, finds that a cultivation through several generations so interferes with the virulence of the organism that it serves as a protective vaccine, setting up all the symptoms of a modified yellow fever, to which the patient does not usually succumb, and which protects him from further attacks of this malignant disease. From 1883 to 1890 there have occurred five epidemics—1883, 1884, 1885, 1888, 1889—during which no fewer than 10,885 people have been inoculated, with a very small death-rate. As the result of Professor Freire's work, a special institute supported by Government was opened in December, 1890; this is to be devoted to the preparation of the yellow fever vaccine. Patients have now, in consequence of the success of the treatment lost all fear of being vaccinated.—*Brit. Med. Jour.*

THE PROPER HOURS OF SLEEP.

The *Lancet*, July 11, 1891, says that the necessity of devoting to sleep several hours in each day is too obvious to admit of serious question. The proper selection of these hours is also, for those who would prolong and usefully employ life, a very needful consideration, though its importance may to some be less evident. We have all met with persons, outside of hospitals and of Parliament, who do half or more of their daily work after nightfall, and sleep long after earlier rising men are awake and busy. Some of these are wont to extol the comfort of their morning slumbers. They describe as immense, the refreshment they receive from six or seven hours thus agreeably spent, and no wonder, for the sense of present satisfaction must be very marked, and that for definite reasons. Man, in common with most of the animal creation, has accepted the plain suggestion of Nature that the approach of night should imply a cessation of effort. If he ignores this principle his work is done against inherited habit, and, so far, with additional fatigue. It follows, too, from our ordinary social conditions, that he must use artificial light, and sustain its combustion at the cost of his own atmosphere. Naturally, therefore, when he does rest his relief is in proportion to his weariness. As in many other cases, however, sensation is not here the most reliable guide to judicious practice. Established custom affords a far truer indication of the method most compatible with healthy existence. The case of the overworked and the invalid lends but a deceptive color to the argument of the daylight sleeper. In them excessive waste of tissue must be made good, and sleep, always too scanty, is at any time useful for this purpose. For the healthy majority, however, the old custom of early rest and early waking is certain to prove in future, as returns of longevity and common experience alike show that it has proved in the past, most conducive to healthy and active life.

ARE WE TOO CLEAN?

In a paragraph under the above heading the *British Medical Journal*, July 11, 1891, says that not many years ago European civilization was in an optimistic phase, and people went about saying that, what with railways, steamers and telegraphs, we might thank heaven that we were born in the nineteenth century. Satiety, dis-illusion, and the increase of the population have thrown a gloom over these old and happy notions. Thoughtful people wish to know if we are really better than our ancestors. One positive fact is ascertained—we are certainly

cleaner. It is difficult to say that anybody can be too clean, but it is easy to understand that a man can clean himself in the wrong way. Dr. M. Ricketts has discovered a skin affection almost peculiar to women who wash and powder too frequently. There is redness, with scaliness and considerable burning. Exposure to draughts increases the symptoms. At times there is pain, causing loss of sleep. The zeal of some American ladies in the practice of the virtue which is next to godliness is marvellous. One is said to have confessed to having applied a well-known cosmetic powder thirteen times in twelve hours, each time after the face had been thoroughly washed with a yet more famous soap. Dr. Ricketts prefers good pure olive oil from the south of France, applied two or three times a day with some soft silk or linen fabric, to the blandest soap. We feel no surprise at the above information as to the evil effects of too much soap. There is such a thing as using too much water, especially if cold or very hot. In our profession frequent washing of the hands is an absolute duty and necessity; yet how well we know that chaps once formed are aggravated by washing, and that glycerine often irritates the hand which it whitens. The roughening of the hand by frequent ablutions is a grave matter, as it diminishes tactile sensibility and is very disagreeable to patients. Thorough drying of the hands after the use of tepid water and a bland soap is the surest way to keep them clean without inducing conditions which cause them to become dirty again with rapidity. As for the cold bath, its dangers are well known. The middle-aged man must beware of it; nor feel ashamed to mingle with its flood half or more of the contents of his shaving-water jug. Otherwise he runs as much risk as he entails on his constitution by violent athletic contests with men twenty years younger than himself, if not more risk, as he always has to find time for his toilet, though his pursuits may keep him from frequent indulgence in sports.

MEDICAL CHEMISTRY.

INCOMPATIBLES OF ANTIPYRINE.

According to Millard and Campbell, the following substances produce precipitates when added to aqueous solutions of antipyrin:

Carbolic acid in saturated solution,
Tannin, (a white insoluble precipitate),
Mercuric chloride, (a white precipitate, soluble in an excess of water),
Infusion catechu,
Infusion cinchona-bark,
Infusion rose-leaves,
Infusion uva ursi,
Solution of extract cinchona-bark,
Tincture catechu,
Tincture cinchona,
Tincture hammamelis,
Tincture iodine, (a precipitate soluble in water),
Tincture kino,
Tincture rhubarb.

The following substances produce coloration when added to aqueous solutions of antipyrin:

Hydrocyanic acid, dilute solution,.....yellow,
Niric acid, dilute solution,.....weak yellow,
Ammonia-alum, dilute solution, dark yellow,
Amyl nitrate, acid solution,.....green,
Nitrous ether, alcoholic solution,.....green,
Copper sulphate,.....green,
Ferrous sulphate,.....yellow-brown,
Ferric sulphate,.....blood-red,
Ferric chloride,.....blood-red,
Syrup iodide iron,.....red-brown.

THE IDENTIFICATION OF TRACES OF ALBUMEN IN URINE CONTAINING BACTERIA.

Adolf Jolles (*Zeitsch. f. Analyt. Chem.*, 29, 407 ; *Ber. Deut. Chem. Ges.* 23, 707,) says that by shaking the urine with "kieselguhr" (diatomatous earth) and then filtering, that the albumen can easily be identified in the filtrate by means of acetic acid and potassium ferrocyanide. In case any albumen remains on the filter, the precipitate is washed with warm caustic potash solution, and the alkaline filtrate acidified with acetic acid and tested with ferrocyanide. (We must not forget that the acetic acid and potassium ferrocyanide test is not an absolutely certain one, as *mucin* as well as albumen is precipitated by it.) The treatment of the kieselguhr on the filter with warm potassium hydroxide solution is of questionable value, as we do not know whether the caustic solution has any solvent action on the bacteria themselves.

THE VALUATION OF MEAT PEPTONES.

An important discrepancy in the method adopted by chemists for the analysis of peptones is pointed out by M. A. Denæyer in a pamphlet of recent issue. In the well

known König process no regard is paid to the determination of gelatine, which it appears is a common constituent of commercial peptone of meat; and as sulphate of ammonia is used for the precipitation of albumose (gelatine being precipitated by the same reagent), the proportion of albumose-peptone is exaggerated. If, as the author states, gelatine enters largely into the composition of many of the preparations in commerce, it becomes a matter of fundamental importance to be able to determine the amount of this body, inasmuch as it is said to present the nutritive value of neither the albumens nor their peptones. The process now published by M. Denæyer admits of the estimation of all three bodies—viz: gelatine, albumose, and peptone. The following is a *résumé* of the method which he adopts. Two grammes of dry peptone in 10 cubic centimetres of water are treated with 90 cc. of 90 per cent. alcohol. The alcohol precipitates the albumose, peptone, and normal jellifiable gelatine, while it takes up the salts and extractive bases and allotropic injellifiable gelatine. The coagulum obtained by alcohol is then dissolved in hot water, any residue of albumens which have been rendered permanently insoluble by the alcohol being filtered off and weighed. To the dissolved portion, which is carefully neutralized, an excess of saturated solution of bichloride of mercury is added. This reagent throws down albumose and peptone, the gelatine remaining in solution. After filtration the clear solution may be freed from mercury by means of sulphuretted hydrogen. It is then filtered, and the gelatine, after concentration of the fluid, precipitated by a saturated solution of ammonium sulphate. On raising the mixture to boiling, the gelatine firmly adheres to the sides of the vessel. It may be washed quickly with cold water and weighed; the weight of the vessel and the entangled sulphate of ammonium being deducted, the amount or normal jellifiable gelatine is given. The quantity of adherent ammonium sulphate is determined by dissolving the coagulum in warm water and triturating with a standard solution of barium chloride. The weight of gelatine so obtained is deducted from the weight of the precipitate given by adding saturated ammonium sulphate directly (as in the König process) to a fresh solution of the alcohol coagulum. As ammonium sulphate precipitates both gelatine and albumose, this last difference gives the albumose. For the estimation of peptone proper two grammes of peptone, freed in the same way from insoluble albumens and extractives, are treated with a solution of acid phosphotungstate of soda, which precipitates the normal gelatine, the albumose, and the peptone. The precipitate is collected on a tarred ashless filter, washed well with water containing hydrochloric acid, dried, and weighed. It is then ignited in a muffle until complete incineration is effected. The weight of the residue and that of the filter are deducted from that of the dry precipitate. This gives the gelatine, albumose, and peptone. On deducting the amount of gelatine and albumose the weight of peptone is gained. The alcohol employed for the precipitation of the albumens and peptones is divided into two portions—one in which allotropic injellifiable gelatine is estimated by evaporating to dryness, taking up with water and treating with ammonium sulphate in the manner already indicated; the other portion is evaporated, and the residue dried to constant weight. From this is deducted the weight of gelatine (injellifiable), and the amount of creatine and salts is arrived at by difference. The process is evidently based on accurate and painstaking observations, and it certainly seems to promise in the hands of careful operators a means for the satisfactory separation and estimation of albumose, peptone, and gelatine. This last body, the author states, whether normal or injellifiable, is not identical, chemically or physiologically, with peptone or albumose, in that it has a greater percentage of nitrogen, and, unlike them, is not organically assimilable. It is therefore desirable to know the proportion of gelatine contained in preparations of this kind, seeing that they are largely advocated and employed as nutrients in the treatment of disease associated with enfeebled powers of assimilation and digestion. M. Denæyer appears to have been one of the first to recognize the presence of gelatine in meat peptones, and his process will in all probability prove a contribution of no little importance to the analytical domain of chemical science.—*Lancet.*

THE CHEMISTRY AND TOXICOLOGY OF THE TUBERCLE BACILLUS.

Weyl (*Deutsche med. Wochenschrift*, 1891) examined, at the Hygienic Institute at Berlin, the product obtained by treating with dilute sodic hydrate, the scrapings from 600 glycerin-agar cultures of the tubercle bacillus. The yellowish turbid mixture coagulated, by gradual cooling, into two layers—an upper, resembling coagulated agar, and a lower, containing small, white shreds. The lower

layer, after treatment with warm dilute sodic hydrate, consisted, microscopically, of folded membranes, and at irregular intervals of apparent, inflated tubes. It contained carbon, hydrogen, sulphur and nitrogen. Special interest attached to it because it displayed the specific staining qualities of the tubercle bacillus. This "white substance" probably represents the capsule of the bacillus, while the gelatinous substance of the upper layer represents the protoplasm of the organism. Analysis of this gelatinous substance places it among the mucins. Solutions of it were prepared and injected subcutaneously into rabbits, guinea-pigs and mice. In the guinea-pigs and mice, at the end of three or four days, local necrosis took place at the site of injection and a crust formed, which fell off in four or five days. From these experiments Weyl concludes that from cultures of tubercle bacilli a toxomucin can be obtained, which he does not believe to exist preformed in the bacilli. —*Amer. Jour. Med. Sci.*

A TEST FOR ACETONE IN EXPIRED AIR.

The presence of acetone in the breath is generally detected by its special odor, which is compared by various authors to that of wine, chloroform, ether, etc. No recent publications, however, describe any method for the chemical demonstration of its presence. Professor De Renzi (*Riforma Medica*, April 25th, 1891)gives a simple methed of estimating qualitatively, and to some extent quantitatively, the amount of acetone contained in the aqueous vapor condensed from expired air. His apparatus is very simple—a small thin-walled bottle fitted with an india-rubber cork through which pass two tubes. This bottle is placed either on ice or in a freezing mixture, and the patient allows the expired air to pass into it through one of the tubes. A few minutes are sufficient to collect enough liquid for examination. The test applied is that of Lieben, which consists in the formation of iodoform by treating the liquid with caustic potash and solution of iodine in potassium iodide. If the precipitate be heated on a water bath the iodoform will be volatilized and be deposited in crystalline form on the cool parts of the apparatus. A solution which contains only 0.01 milligramme of acetone will give the precipitate of iodoform in from one to three minutes. A stronger solution will give the reaction immediately on adding the reagents. It will be easily seen that the same method may be made to yield quantitative results. In order to estimate acetone in the urine, it is necessary to distil off the aqueous portion, as the reaction will not take place in presence of the urinary salts. This operation is both tedious and unpleasant, and the author is of opinion that examination of the breath as above described will be sufficient, in a case of acetonæmia, to detect the presence of acetone. He has found, too, that in slight cases it is possible to obtain the iodoform reaction from the breath, when examination of the urine yields only a negative result. It may be mentioned, in conclusion, that the breath in health never contains acetone, and application of the test will not give the faintest trace of iodoform.—*Brit. Med. Jour.*

News and Miscellany.

THE SECOND TRIENNIAL SESSION OF THE CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

Washington, D. C., June 24, 1891.

Circular No. 1:

The Committee of Arrangements takes great pleasure in announcing to the members and invited guests that the arrangements are sufficiently advanced to assure the success of the Second Triennial Session of the Congress of American Physicians and Surgeons, which will be held in this city during the 22d, 23d, 24th, and 25th of September, 1891.

A number of distinguished physicians and surgeons from abroad have accepted the invitation to attend, among whom may be named Mr. Thomas Bryant, Mr. B. E. Broadhurst, Mr. A. E. Durham, Mr. Reginald Harrison, Surgeon General Sir W. E. McKennin, Mr. U. Pritchard, Mr. F. Treves, Sir William MacCormac, and Drs. James G. Glover and William M. Ord, of London, England; Drs. McCall Anderson and W. T. Gairdner, of Glasgow; Mr. E. H. Bennett and Professor J. J. Cunningham, of Dublin; Professor John Chiene and Dr. J. Battey Tuke, of Edinburgh; Professor H. Krause and Dr. F. Beeby, of Berlin; Professor Curschmann, of Leipzig; Professor Hoffa, of Wurzburg; Professor Kuhne, of Heidelburg; M. Emil Juval, M. E. Landolt, and Dr. Pozzi, of Paris; Dr. A. Musso, of Turin; Dr. Von Mozengeil, of Bonn; Dr. Lowenber, of Paris; and Dr. Rafail Lavista, of Mexico.

The sessions of the Congress will be held in the Main Hall of the Grand Army

Building, 1412 and 1414 Pennsylvania Avenue, from 3 to 6 P. M., daily.

The President's Address will be delivered in the Lecture Hall of the National Museum, Wednesday, September 23d, at 8 P. M., followed by the Reception of the President, from 9.30 till 12. Order of Executive Committee. The Army Medical Museum will be open the same evening.

The sessions of the Societies will be held according to the programmes of each, respectively, in the places as follows:

American Surgical Association, Main Hall, Grand Army Building, 1412 and 1414 Pa. Ave.

Association of American Physicians, Hall No. 1, Grand Army Building, 1412 and 1414 Pa. Ave.

American Climatological Association, Hall No. 2, Grand Army Building, 1412 and 1414 Pa. Ave.

American Gynæcological Society, Lecture Hall, Columbian University, 15th and H Sts. N.W.

American Laryngological Association, Parlor A, Arlington Hotel.

American Neurological Association, Parlors 182 and 183, Arlington Hotel.

American Orthopedic Association, New Reception Room, Arlington Hotel.

American Otological Society, Ladies' Parlor, No. 1, Arlington Hotel.

American Ophthalmological Society, Ladies' Parlor, No. 2, Arlington Hotel.

American Physiological Society, Parlor 181, Arlington Hotel.

The officers of the American Dermatological Association and the American Association of Andrology and Syphilology have made their arrangements with the Shoreham for places of meeting.

Office of Registration, Parlors 1 and 2, Arlington Hotel. From this office the mail of members and guests will be distributed, and the city residence of each member or guest can be ascertained.

The Association of American Anatomists will meet in this city during the sessions of the Congress, and will occupy Hall No. 3, Grand Army Building. The American Pædiatric Society will meet here September 23d and 24th, in the Lecture Hall of Columbian University, 15th and H Streets N.W.

The Congress will be composed of the members of the constituent societies and invited guests.

A registration fee of five dollars will be required of every member of the constituent societies who may register; invited guests will not pay the fee. Order of Executive Committee.

Participating societies can "accredit visitors to the Congress, who shall pay the registration fee, but shall not be privileged to participate in the deliberation of the Congress." Order of Executive Committee.

A copy of the transaction of the Congress will be sent to each person who may register.

Only those who may register, invited guests, and ladies accompanying them will be admitted to the Reception of the President.

Secretaries of constituent societies are requested to supply this Committee with the names and addresses of "accredited visitors."

The evenings of Tuesday, September 22d, and Thursday, September 24th, are left to the societies.

Members of the American Surgical Association and of the Association of American Physicians will conjointly entertain their foreign guests at dinner at the Arlington Hotel, Thursday, September 24th, at 8 P. M.

The American Gynæcological Society has also arranged for a dinner at the Arlington Hotel, Thursday evening, September 24th. The American Pædiatric Society give a dinner 24th September.

Other societies that intend to entertain their foreign guests are requested to communicate with this Committee.

Arrangements are in progress to secure reduction of railway fares. As soon as completed, the information will be communicated to each member and "accredited visitor."

The Arlington Hotel offers accommodations at the rate of four dollars per day, and the Hotel Arno offers rates "on the American plan at $3 and $4 per day, on the European plan, $1 each per day. Exclusive use of bath, $1 extra."

A blank certificate of registration will be sent to each member and "accredited visitor." The Committee requests each person receiving such certificate to fill the blanks and return it, with the fee, to Dr. John S. Billings, Treasurer of the Congress.

The American Pomological Society, and perhaps other societies, will meet in this city September 22–25. The Committee therefore suggest to the members an early arrangement for hotel accommodations.

Inquiries relating to railway fares must be addressed to Dr. S. S. Adams, 1632 K St.

A complete roster of membership of the Congress has been prepared, with post-office address and society to which each member belongs.

The Committee will take pleasure in answering any inquiry relating to the local arrangements of the Congress.

GYNÆCOLOGY IN SPAIN.

On February 23d of the present year, the Spanish Gynæcological Society appointed a committee consisting of Drs. G. Alarcon, E. Gutiérrez, A. Cospedal, and F. de Cortejarena, to consider the advisability of establishing a gynæcological institute in Madrid. This committee has now reported that the creation of such an institution is urgently needed, not only in the capital, but in each of the provinces, as at present next to no provision is made in Spain for the treatment of women suffering from diseases peculiar to their sex. In the Madrid hospitals there are only a very few beds for such cases, and elsewhere things are even worse. The Committee recommend that a fully equipped gynæcological institute be forthwith established in Madrid with competent teachers and special courses of instruction, not only in gynæcology, but in the anatomy, physiology, and hygiene of the female sex, obstetric operations, gynæcological surgery, etc. The building should be constructed to accommodate not more than seventy or eighty beds; the obstetrical and gynæcological departments should be kept separate from each other, and all the arrangements should be in accordance with the most advanced hygienic principles. The institute should stand in an isolated position surrounded by gardens.—*Ex.*

CREMATION IN ARGENTINA.

Cremation seems to have acquired a sure foothold in the Argentine Republic. Since 1886 the total number of cremations carried out there has been 6,789; in 1890 alone they amounted to 2,085. A law exists in Argentina to the effect that the bodies of all persons dying of infectious diseases and the fragments that remain of corpses that have been dissected must be burnt.—*Ex.*

SAHARA AS A HEALTH RESORT.

It is reported that European invalids and other persons in search of quiet and a mild climate for winter are beginning to turn their attention to the oases on the northern border of the great Sahara, where the climate is very equable. Railway communication through Algeria makes these places less inaccessible than formerly.—*Ex.*

THE DOCTOR'S EARNINGS.

According to Dr. Jarvis' tables, the average of the lives of physicians is fifty-six years. If you begin practice at twenty-four, your active life prospect will be thirty-two years, and from a thousand to fifteen hundred dollars will represent your average yearly income. Now, were you (through God's mercy) to practice these thirty-two years without losing a single day, and collect (say) eight dollars every day of the time, you would receive but $93,440. Deduct from that amount your expenses for yourself and your family, your horses, carriages, books, periodicals, and instruments; your taxes, insurance, and a multitude of other items for the whole thirty-two years (11,680 days), and then, so far from being rich—you would have but little, very little, left to support you after you naturally reach the downhill of life, or are broken down in health, and faculties deteriorated, and in need of a physician yourself, through worry, anxiety, and fatigue, in the discharge of your duty.—*Kansas Med. Journal.*

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

An extraordinary comitia of the College was held on Tuesday, June 16th. Sir Andrew Clark, Bart., M. D., president in the chair.

The Censors' Board nominated Dr. Pye-Smith Lumleian Lecturer for the ensuing year, and Dr. Sidney Martin, Goulstonian Lecturer. A communication was read from the Secretary of State for War promising the promulgation of a Royal Warrant in respect of the Army Medical Department, as already notified in our columns. The President observed that it could not be said that the College was unable to exert any public influence, as since it had first moved in the matter every demand that had been put forward had been granted save one, and that was the formation of an Army Medical Corps, which, being very costly, would necessarily take some time.

On the motion of the Senior Censor, it was resolved that the Council of the College might confer with others than fellows of the College on the question of the five-years curriculum, and the necessary rearrangement of studies entailed thereby.

Communications were received from the Secretary of the Royal College of Surgeons.

The rest of the meeting was occupied with a subject declared to be *secreta collegii*, and at 7 o'clock the further discussion was adjourned till Saturday (June 20th).

THE JOHN HOPKINS CO-EDUCATIONAL MEDICAL COLLEGE.

Miss Mary Garrett has contributed an additional $10,000 to the endowment fund of the proposed John Hopkins Medical School, says the Baltimore correspondent of the *Journal of the American Medical Association.* In a letter dated April 27th, addressed to President Dobbin, of the Board of Trustees, she makes this offer payable October 1, 1892, subject to the following conditions: That by February 1, 1892, the trustees raise the remainder of the sum necessary to bring the endowment up to $500,000—the minimum limit proposed by the trustees—and further that the trustees shall give notice in February, 1892, that they will open the school in October, 1892, and shall actually open it then. The committee of ladies organized to raise $100,000, having accomplished their object has disbanded. The following represents the present status of this endowment: The entire sum raised by the committee of ladies of Baltimore and elsewhere and paid over to the trustees May 1st was $111,000; there were already in hand additional funds sufficient to raise this amount to $178,780. In order to avail of Miss Garrett's offer, it is therefore necessary to raise $221,219. The trustees have accepted her offer and have resolved to endeavor to raise the balance required. Of the $111,300 raised by the ladies, Baltimore contributed $68,882; the next largest contribution was Boston's, $20,231, and Philadelphia's $8,075. If the ladies would only raise $200,000 to endow some medical college already in existence it would do a vast deal more good. The college in this city, for example, would be enormously helped by it.—*N. Y. Med. Jour.*

The Mississippi Valley Medical Association will hold its 17th annual session at St. Louis, Wednesday, Thursday and Friday, October 14, 15 and 16, 1891. Reduced rates and an excellent programme will bring out a large attendance. The medical profession is respectfully invited. The officers are as follows:

President.—C. H. Hughes, M. D., 500 N. Jefferson Avenue, St. Louis.

Secretary.—F. S. McKeith, 57 W. 7th st., Cincinnati, Ohio.

Chairman Committee of Arrangements.—I. N. Love, M. D., 501 N. Grand Avenue, St. Louis, Mo.

THE TRAGIC AND LAMENTABLE FATE OF AN ERRANT BACILLUS KOCHII.

AN HYSTERICO-BIOGRAPHICAL, LABORATORIOUS AND EPICAL EPISODE DONE INTO POETRY OF THE PRESENT DAY.

BY KATISHA KATZENJAMMER, OF THE BACTERIOLOGICAL INSTITUTE.

Translated from the Japanese.

A little spore in a culture grew,
Listen to my tale of woe!
Embedded in a mass of glue,
Till a full fledged bacillus it sprang into view,
Listen to my tale of woe!
Now day by day its ambition grew;
Listen to my tale of woe!
Like the witch in Macbeth who made the stew,
It said to itself, "I'll do! I'll do!"
Listen to my tale of woe!

It saw its chance in a day or two:
Listen to my tale of woe!
A draught of wind through the laboratory blew,
And out of a window the bacillus flew.
Listen to my tale of woe!
In a neighboring orchard a little peach grew;
Listen to my tale of woe!
The little bacillus came there too,
And Johnny Jones with his sister Sue,
Listen to my tale of woe!

Now, they ate the peach of emerald hue,
Listen to my tale of woe!
And swallowed the little bacillus too.
Which well in life its mission knew.
Listen to my tale of woe!
Now, the doctor was called to attend them too,
Listen to my tale of woe!
Who took from his pocket his microscope true,
And brought the bacillus into view.
Listen to my tale of woe!

He said, "Here's the cause of this cry and hue,"
Listen to my tale of woe!
For the comma-bacillus well he knew;
And he stained it red and he stained it blue,
Listen to my tale of woe!
In Susie's abdomen a little glue;
"Ah! here is infection and zymosis too,
Tis sad to say; Boo-hoo! Boo-hoo!"
Listen to my tale of woe!

Now, all kind friends my advice to you,
Listen to my tale of woe!
Is, when you are walking with a maiden true,
Avoid the peach of emerald hue!
Listen to my tale of woe!
And if, like Adam, you are tempted too,
Listen to my tale of woe!
Remember the fate of John and Sue,
Who ate the peach of emerald hue,
And the wicked bacillus that got stained blue,
Listen to my tale of woe!

CHORUS.
Hard trials for them two,
Johnny Jones and sister Sue,
And the peach of emerald hue,
Also the comma bacillus too,
Listen to my tale of woe!

—*Pacific Druggist.*

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

The deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. Manuel Moreno de la Torre, editor of the *Crónica Médico Quirurgica*, of Havana.—Dr. Bisping, of Mülheim.—Dr. L. Jacoby, the eminent Breslau otologist, at the age of seventy-four.

OXFORD UNIVERSITY MEDICAL SCHOOL.

An important step has been taken at Oxford University in the furtherance of medical education. Convocation last week by 193 votes to 46 passed a decree authorizing the expenditure of £7,000 for dissecting-room, museum, working rooms, and lecture theatre for the department of human anatomy. The vote was proposed by Professor Price, F. R. S., and supported by the President of Corpus (Dr. Fowler), Dr. Theodore Williams, Dr. Church and others. The opposition on the other hand was led by the Warden of All Souls (Sir W. Anson.) Another important matter was also decided at the same meeting, namely, that there should be an extension of the department of Animal Morphology under the direction of the Linacre Professor of Comparative Anatomy. Verily, this is a forward movement on the part of the University which has come none too soon. The condition of the Medical School at Oxford has been scarcely less than a by-word for many years. We trust that a new order of things is now about to be inaugurated. With such splendid means at hand, why should the Oxford School not take a worthy position in the cause of medical education? There is no reason for this saving the want of organization; a beginning has now been made, let it bear good fruit and be the means of taking away a reproach from an honored University.—*Med. Press.*

MEDICAL AND SURGICAL REPORTER

No. 1796. PHILADELPHIA, AUGUST 1, 1891. Vol. LXV.—No. 5.

Clinical Lecture.[1]

APPENDICITIS—OPERATION.

BY JOHN ASHHURST, Jr., M. D.,

BARTON PROFESSOR OF SURGERY, AND PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF PENNSYLVANIA, SURGEON TO THE PENNSYLVANIA HOSPITAL.

Gentlemen:—The first patient that I show you to-day is a young man, twenty-four years of age, who presents an interesting condition, the treatment of which may be said to be one of the burning questions of surgery at the present time. The patient was admitted to this Hospital last July, suffering with typhoid fever. He recovered and left the house August 15, but was again admitted in September with perityphlitis, which is an inflammation around the cæcum. He remained in the Hospital nine days, got better and went out. He again returned on December 9, after an interval of three months. On this occasion he said that five days before admission he had been taken with pain in the right iliac fossa, and with symptoms in every respect similar to those of the former attack. In the abdomen, in the right iliac region, there was a distinct mass four or five inches by two inches, painful on pressure. The temperature was 101.4° F. The urine was of a dark color, but contained no albumen or sugar. The amount passed in 24 hours was thirty-four ounces. The treatment consisted in the administration of calomel and soda until the bowels were moved. Blisters were applied over the painful region. The day following admission the pain was much relieved, and the temperature had fallen to 99° F. The bowels moved easily. December 12, there was still improvement; the mass was not so tender, and was smaller. On the 15th, there was no pain and the mass was still smaller. On the 19th, he was discharged with some slight resistance in the right iliac fossa, but no pain.

Such was the history until he presented himself the day before yesterday with the statement that three days before he had had a return of pain in the right iliac region. There is now a mass in this region which is not as diffuse as in the last attack. While there is some hardness and resistance in the line of the groin, yet the principal tumor appears to be circumscribed, two inches inside of the anterior superior iliac spine, in other words, in the position of the vermiform appendix. The patient has great pain and has lost much sleep, and there is great tenderness not only on firm pressure but on the slightest touch, with a faint suspicion of doughiness, suggestive of deep-seated pus. There is also high temperature and marked constitutional disturbance.

The first question in this case is in regard to the diagnosis, and the second in regard to the treatment. There can be no doubt, I think, that it is a variety of what is called perityphlitis. It seems to me that the inflammation must be more localized to the appendix than it was in the former attack, and that it is proper, therefore, to designate the present condition by the somewhat clumsy term of appendicitis.

With regard to the treatment: The prevailing tendency is toward exploratory operations in all cases in which inflammation occurs in this situation. I am sufficiently conservative to believe that indiscriminate operation in these cases is injudicious, and that a very large number of cases of perityphlitis and typhlitis will end in recovery under simple treatment and not recur, or that if they do, the patients may still get well without any particular danger, and have no special trouble as the result of the disease. In other cases, the disease will run on to the production of peritonitis, sometimes general peritonitis, but even under these circumstances it does not seem to me that the line of safety is, as a rule, in operation. I be-

[1] Delivered at the Pennsylvania Hospital.

lieve, however, that there are some instances, and I think that this is one, in which we can fairly well localize the inflammation to the appendix. There is no general peritonitis. There does not appear to be any great extent of local peritonitis. There is reason to believe that the appendix is inflamed, possibly surrounded by a collection of pus, and probably containing some concrete mucus, possibly a foreign body. We have to consider what will be the condition if the patient is let alone. He may convalesce as on previous occasions, and may go a long while without recurrence. On the other hand there is a certain amount of risk that the collection of pus, which I suspect is present, may burst, and that the pus will be poured out into the peritoneal cavity leading to general suppurative peritonitis. In this particular case, it seems to me that it is justifiable to make an exploration, and, if we find that the appendix is diseased, to remove it, provided that it is not so firmly bound down as to render removal impossible.

I do not recommend an operation in these cases when there is simply perityphlitis without the inflammation being localized. Nor on the other hand do I recommend an operation where the case has run on to the production of general peritonitis, unless it is suppurative peritonitis. Then, although the patient will probably die, the only hope lies in the evacuation of the pus and the washing out of the abdominal cavity. Ordinary cases of peritonitis following typhilitis admit of safer treatment than by opening the abdomen. The ordinary treatment of peritonitis will in these cases give a better hope of recovery. When there is a localized inflammation which can almost be traced to the appendix itself, and when pus is probably present, I think an operation is justifiable. It is therefore only in exceptional cases that I recommend an operation.

The question has been agitated as to the time when the operation should be performed; whether it should be done when the part is inflamed, or whether in the interval between the attacks, when the patient is well. Here again I am conservative enough to say that if the patient is well, he should be let alone. The time to operate is when he is suffering. Those surgeons who hold that opening the abdomen is attended with little or no risk believe that it is right to operate when the patient is well. In my judgment, the time to operate is when there is danger to life, and yet not such imminent danger as in general peritonitis.

My colleagues, Drs. Hunt and Morton, have examined this case, and agree that it is a proper one for exploration. On the former occasion the patient was so much improved twenty-four hours after admission, that he was practically convalescent. If I had found the same improvement follow in the present attack, I should have been disposed to recommend that operation be not resorted to. There has, however, not been such improvement as to make it probable that spontaneous recovery will occur.

I shall now proceed to the operation. The parts have been rendered aseptic, and I shall make an incision in the direction of the linea semilunaris, making a part of the incision over the point which we know to be the usual position of the appendix, that is two inches inside of the anterior superior spine of the ilium. The incision is four inches long, and the bleeding is controlled with hæmostatic forceps. Cautiously cutting down to the peritoneum, I tie the vessels with catgut ligatures before opening it. Incising the peritoneum there is at once a discharge of pus. This cavity, which is walled off by adhesions from the general peritoneal space, is irrigated with hot water, and with some difficulty I am now able to bring the appendix into the wound. This I cut off after tying it with a strong silk ligature. After the cavity is thoroughly irrigated, I insert a glass drainage tube, and suture the peritoneum with catgut, then uniting the skin and muscles with silver wire. The usual antiseptic dressings are applied and the patient is returned to his ward.

[Convalescence was uninterrupted, the drainage tube was removed in a few days, and the patient left the Hospital after some weeks, entirely recovered].

COMMUNICATIONS.

RELIEF OF PARTIAL INTESTINAL OBSTRUCTION FOLLOWING THE REMOVAL OF THE UTERINE APPENDAGES.

BY CHARLES P. NOBLE, M. D.

SURGEON IN CHARGE OF THE KENSINGTON HOSPITAL FOR WOMEN, PHILADELPHIA.

Questions concerning the limitations of abdominal surgery for good and ill, are still pressing for solution. Conditions which demand immediate operation (which positively contra-indicate abdominal section) or which render delay advisable, are constantly con-

fronting the surgeon. Because of the multitude of diseased conditions found within the abdomen, the complexity of the problems involved, and the well recognized impossibility of making absolute diagnosis in all cases. Greater responsibility is thrown upon the surgeon than is the case in the surgery of other regions of the body. This aspect of the subject, while it should stimulate the surgeon to make use of all known means in reaching conclusions, should also prevent him from forming absolutely fixed opinions except upon very positive evidence. The grounds upon which to advise abdominal section and upon which to refuse it, are not yet fixed.

More especially is this true when the symptoms complained of, cannot be explained on physical grounds. Some have gone so far as to decry operation in all cases in which a bi-manual examination will not reveal some gross physical lesion. And yet such a rule will leave many women chronic invalids who can be cured or improved by operation. The effect of cystic and of atrophic ovaries, and of chronic ovaritis upon the health of women, is well recognized, and yet, these conditions are by no means always susceptible of diagnosis by bi-manual examination. The relation of adhesions to pelvic pain is always obscure. Even more gross pathological lesions may not be appreciated during the bi-manual examination. In some cases a consistent history of suffering referred to the pelvis must be sufficient to justify operation. This indication, of course, opens the door to indiscriminate and unnecessary operating in the hands of those so inclined, but this constitutes simply an abuse of the indication. Exploratory abdominal section has so little danger that it is justifiable and urgent after simple means fail in all cases in which life is endangered or health is destroyed by pelvic (abdominal) disease, not plainly inoperable.

As illustrating this principle, the case of Mrs. R. is reported. A surgeon who is a staunch opponent of operation except for gross diseases, refused to operate upon her, alleging that her sufferings were hysterical, because he had removed her uterine appendages, and because he could find nothing further to remove.

The woman's history has been prepared for me by Dr. Deekens, and is as follows:

Mrs. R., aged 29 years, German, of good family history, came to America seven years ago. She had always been strong and healthy up to that time. She worked in the country, and while over-exerting herself, lifting heavy weights, suddenly felt a sharp cutting pain in both groins, followed by great faintness, necessitating rest in bed for a day or two. Her subsequent period was intensely painful, and was followed by profuse metrorrhagia, which remained almost constant, producing a high degree of anæmia. She remained in this condition a year, still doing her work when able. At the end of that time she was married. Pregnancy followed shortly afterwards, and three months later while working hard, was seized with sharp groin pains as before, accompanied by abdominal cramps, succeeded by a free hæmorrhage containing masses of clotted blood. A physician was called in who pronounced it a miscarriage. In about six months she had a recurrence of her former pains, followed by symptoms of pelvic peritonitis with constipation, dischezia, dyspareunia, dysecoia, etc. Under the rest cure for several months, coupled with antiphlogistic treatment, she improved, and shortly after became pregnant. She was delivered instrumentally of a very large child.

The subsequent history is merely a repetition of the past, with intermitting attacks of pelvic inflammation, of greater or lesser severity, partially relieved temporarily by rest, poultices, glycerine tampons, etc. She was then advised to enter a hospital, and within the next few years was an inmate of four of the general hospitals of the city. She was by this time a broken down hysterical hypochondriac, not being free from pain for an hour. In April 1889, a double ovariotomy was performed, both ovaries being found enlarged and cystic. Partial relief followed the operation temporarily, but later she suffered extremely from abdominal pain.

A year later we again find her a hospital inmate. At this time she could not walk owing to the excruciating pains caused by locomotion. The surgeon-in-chief decided that a secondary operation was not indicated, presuming that the symptoms were mainly of a hysterical order. The patient's sufferings were real, however, and she sought admission to the Kensington Hospital for Women. Her condition was one of profound anæmenia, malnutrition and neurasthenia, and the chief complaints were, pain on locomotion, defecation and coition. Special stress was laid on the agony accompanying defecation. On examination a hard, sensitive mass was found to the left and behind the uterus, evidently connected with the stump from the left ovary and tube. Simple intestinal adhesions or septic inflammation

about the ligature was suspected. The uterus was also found bound firmly in retroflection. These conditions were considered sufficient to account for the pelvic pain, and an exploratory incision was advised and gladly accepted.

On opening the abdomen, the uterus, small intestines, rectum, and stump of the left ovary and tube, were found firmly matted together. A beginning was made by freeing the uterus, when the intestines were, with long-continued effort, separated.

One knuckle of ileum was adherent deep in the pelvis, and the peritoneal and muscular coats were torn off in detaching it, necessitating sutures. The mass now consisted of thickened, broad ligament, and adherent rectum. As this is a fairly stationary organ, its separation was not attempted. No evidence of pus was found about the old pedicle. Irrigation and drainage completed the operation. The convalescence was interrupted by the appearance of symptoms of obstruction of the bowels on the second day, the most prominent symptoms being abdominal pain and increasing tympany and vomiting.

In anticipation of this possibility, powders of calomel (gr. $\frac{1}{12}$) had been given hourly, commencing on the first day. Enemas of turpentine and glycerin, and of soap suds given through the rectal tube, for a long time proved ineffectual. Concentrated solution of citrate of magnesia was given and rejected. The bowels were finally moved on the fourth day, after an enema of turpentine, Epsom salts, glycerin and water, given through a soft rectal tube, pressed up into the colon. Threatening symptoms at once subsided, and the patient made an uncomplicated recovery.

At the present time, five months after the operation, she has gained (11) eleven pounds, has done her own house-work, which she has not done for four years, is entirely relieved of pain in defecation, and for the first time in four years, says she is without any pain whatsoever. While her general condition is much improved, she is still markedly anæmic, and to completely restore her to health, much time and improved hygienic surroundings will be necessary. The conditions found, amply justified operation, and the result secured has been most gratifying.

The operator who removed the uterine appendages, and who refused a second operation, is a general surgeon. While he invaded the domain of the gynæcologist to remove the uterine appendages, yet, he overlooked the symptoms pointing to intestinal adhesions and partial obstruction of the bowels—conditions coming within the province of the general surgeon. These facts are of interest, as bearing upon the question of the advisability of general surgeons doing pelvic surgery; and especially of the establishing of departments for gynæcology in general hospitals.

In conclusion, I would urge that while it is prudent and necessary in general to require objective evidence of grave pelvic disease before counseling operation, yet, that there are cases, in which a consistent history of pelvic pain, together with the evidence of disease in the general condition of the patient, and the failure of simpler methods of treatment, requires, that the surgeon should offer to the patient the possible results to be obtained after making an accurate diagnosis by exploratory section.

LAVAGE OF THE STOMACH.*

BY MEFFORD RUNYON, M. D., NEWARK, N. J.

My subject to-night has been chosen in the hope of obtaining the expression of your opinion upon the merits and demerits of a method of treating stomach diseases, which in the hands of many has proved itself of considerable practical importance. My own experience has necessarily been very limited, and I shall attempt nothing further than briefly to state, the literature of the subject I have had at my command, and give roughly the histories of the few cases I have so treated.

Lavage of the stomach was not practised as a routine method of treatment until 1867, when Küssmaul commenced using the ordinary stomach pump with its stiff tube and suction and force syringe, in cases of dilatation of the stomach following chronic catarrhal inflammation. He obtained good results, but many objected to the treatment because of the inconvenience and danger of the instrument used. These objections were overcome by the introduction by Taucher in 1879 of the soft rubber stomach tube in place of the stiff one employed by Küssmaul, and the application of the principle of the syphon instead of the suction and force syringe. Taucher's tube has been modified, but his method of applying the treatment is the one commonly used to-day.

I show you here the instrument which is in in general use at the present time. It consists

*Read before the Orange Mountain Med. Society.

of a soft, flexible, red rubber catheter 30, inches long, ⅓ inches in diameter, having near its closed extremity two "velvet eyes." To the open extremity the rest of the apparatus consisting of a glass funnel and a piece of black rubber tubing 40 inches long, is attached by means of a short glass tube. There is a stomach tube sold, against which I would warn you, made of black rubber throughout, open at the stomach end and very flexible. I have attempted to use this instrument on several occasions, but have never been able to introduce it into the stomach. It would invariably curl upon itself in the patient's mouth, and no amount of effort would force it past the pharynx. But the tube I have shown you can almost invariably be passed with little difficulty. These are its advantages. It is cheap, simple, readily cleaned, easy of introduction convenient and safe.

METHOD OF INTRODUCTION.

The patient should be placed in a chair with a straight back, or on a stool, the operator standing in front. The patient's head should be kept *straight*; if flexed or extended, it is difficult to pass the tube into the œsophagus. Many have recommended oiling or greasing the tube before it is introduced, but this seems often to retard rather than facilitate its passage. The taste of the oil, even the sight of the oiled tube, is sufficient to nauseate many. All that is generally needed is to dip the tube into the solution you are about to use; this warms it, and the abundant secretion of saliva induced by the mechanical irritation in passing the instrument, is all the lubricant required. A word to your patient as to the sensations he may expect is advisable before attempting the introduction of the tube, usually the more intelligent persons are those with whom the least difficulty is experienced.

The patient's mouth should not be opened widely, for the muscular effort made in separating the jaws hinders an easy introduction. Pass the tube gradually into the pharynx; as it reaches this point a spasm of the muscles almost always occurs; pause for a moment until this subsides, and then quickly, but not hurriedly, push the instrument on into the œsophagus. If instead of passing readily, the tube curls up in the patient's mouth, it is better to withdraw it and start afresh than to continue ineffectual efforts to pass it. No difficulty is usually experienced after passing the pharynx until the stomach is reached; here the irritation of the tube against the collapsed walls of the organ often induces severe efforts at vomiting. A little of the solution you are to use, poured quickly into the tube, separates the walls of the stomach, thus removing them from the cause of irritation, and the vomiting ceases almost immediately. When the tube has been well introduced beyond the cardiac opening, the liquid should be poured in. Holding the funnel above the level of the patient's head, the operator should allow the solution to flow in until the patient, by a sign previously agreed upon, complains of a sensation of fullness, when the funnel is depressed quickly before the last of the liquid has left it, to a level below that of the stomach. This converts the tube into a syphon and the organ is quickly emptied. Usually little difficulty is met with in removing the stomach contents by means of the syphon. Occasionally bits of undigested matter or mucus clog the tube, but these can generally be removed by allowing a little more liquid to flow in. If this method should fail to clear away the obstruction, it may be necessary to remove the tube and cleanse it. The quantity of liquid used at any time will depend entirely upon the case under treatment. It will vary from a pint to several quarts. The most I have ever been able to use in any case has been two and a half quarts, and this in one of dilatation, the result of chronic catarrhal inflammation. The quantity removed should always be compared with that introduced into the stomach. A great variety of solutions have been recommended for use in lavage of the stomach. The one selected will depend upon the object the physician may have in view. If the desire is simply to cleanse the organ, or to remove its contents for diagnostic purposes, plain water, warm or hot, is best. Indeed in the great majority of cases water is all that is needed. Occasionally, when there is a good deal of fermentation going on in the stomach antiseptic solutions of boric acid, resorcin or carbolic acid seem to give better results than water alone. Bicarbonate of soda, in solution, or any of the simple alkalies are sometimes used to advantage. If, where there is a good deal of pain and irritability of the stomach, subnitrate of bismuth be suspended in water and the solution allowed to remain in the organ until the bismuth settles, great relief is often obtained.

The most convenient time to practice lavage, as a means of treatment, is in the morning before the injection of food. I say as a means of treatment, for if it be employed for diagnostic purposes, it is often better, and

after food has been taken in this way, it is possible to determine how well the stomach is digesting any special article of diet. In practicing this treatment in my office it has been my custom to advise patients to take a glass of hot milk early in the morning, at least three hours before coming. This I have found is sufficient to stay the stomach while it does not in any way interfere with the process of washing out. The length of time it is necessary to continue this method of treatment will, of course, vary greatly in different cases, a single application may be all that is required in an attack of acute indigestion, while in long-standing cases of an inflammatory nature it may have to extend for months and even years. Where it has to be continued for a long time, it is not necessary for the physician to carry it on himself. After a week or two of practice the patients learn to do it quite as well, and a tube may be entrusted to them with instructions how and when to use it. I have at the present time several patients who are washing out their stomachs one or more times each week, and doing it apparently with as little concern as they would wash their faces or brush their teeth.

In what cases may lavage of the stomach be used? I have already stated that when Küssmaul first introduced the treatment it was employed only in cases of dilatation of the stomach following upon a chronic catarchal inflammation, and it is still in these cases that it is most frequently employed. But the last few years have given it a far wider range of application, until, at the present time there is hardly a disease of the stomach in which it has not been used. Acute indigestion, or dyspepsia, chronic dyspepsia, alcoholic gastritis, ulcer of the stomach and cancer have all been treated in this way, and with satisfactory results. I have known even of a case of that so-called disease, nervous indigestion, miraculously cured by a few applications of the gastric syphon. How much moral effect had to do with the cure, I am not prepared to say, but it relieved me of the fast becoming obnoxious presence of my patient, besides bestowing upon me her warmly expressed gratitude.

In the stomach diseases of children it is fast becoming a well recognized means of combatting successfully these dangerous symptoms which arise so suddenly, and often terminate so fatally. Seibert has studied its use in over 500 cases having used it in acute gastritis, cholera infantum, acute indigestion, chronic dyspepsia. He reports most satisfactory results. Taucher has recommended its use in very young infants, and reports a case of a child 27 days old, where there was persistent vomiting accompanied by constipation and extreme emaciation; prompt and permanent benefit was obtained by washing out the stomach.

Leo has reported over two hundred cases in children treated by lavage, and his experience has been very favorable to its use.

I could occupy much of your time to-night in describing the cases and the results obtained by those I have mentioned, but to most of you it would simply be repetition.

I have described to you briefly, gentlemen, this method of treatment. I have used it myself in about 40 cases, embracing acute dyspepsia, chronic dyspepsia, chronic catarrhal inflammation, with and without dilatation and ulcer of the stomach; with a very few of these I have used it only once, the patients disappearing never to return. Whether a miraculous cure was effected, or the patients were disgusted with the treatment I have never been able to determine. These, however, have been the exceptions. With the rest, I have found it convenient, easy of application, not markedly unpleasant to the patient, free from danger, and accompanied by the most gratifying results. In the light of this limited experience, I am free to say, that in no other single method of treating stomach diseases have I found as much satisfaction as in this.

ANTISEPTIC TREATMENT OF WOUNDS.[1]

BY H. J. WARMUTH, M. D.,

SMYRNA, TENN.

Nothing delighted the sight of the old-time surgeon so much as the appearance of healthy pus in wounds, while to-day we endeavor not only to prevent suppuration, but at the same time to reduce all wounds, as it were, to a condition of subcutaneous injuries, in order to induce healing by primary union.

We are taught that suppuration is only various forms of fermentation, or of bacterial growth, and that wound fever, erysipelas, pyæmia, etc., are not accidents, or owing to a vitiated constitution, but are due to germs imported into wounds from without. Antisepsis is the gospel of absolute cleanliness, hence antiseptic surgery requires that anything coming in contact with a wound, should be perfectly free from germs, there-

[1] Read by title before the Tennessee State Medical Society, April 14, 1891.

fore the surgeon's hands, especially his finger-nails, instruments, sponges, dressings, etc., should be aseptic, in order to keep wounds free from suppuration.

There are many in the ranks of the profession to-day who are skeptics, or do not pay any regard to the antiseptic management of wounds, either from ignorance of the details or from a desire to follow the lead of a few eminent surgeons. We must not forget, however, that Lawson Tait is one of the quickest and most successful operators on record, and that in all his operations, wound surfaces are exposed to the action of the air but a minimum of time, and while he discards all antiseptics, yet he insists upon the most scrupulous cleanliness in his own behalf, and also on the part of his assistants and nurses, before, during and after each operation. A disregard of antiseptic principles has been productive of very serious consequences to patient and surgeon. Suppose we were to perform an amputation, and dress the stump according to ancient usage? Removing the first dressing we will probably find suppuration, afterwards, perhaps, sloughing. After a tedious siege the patient recovers and consults a lawyer. The result will be a suit for malpractice. The Court will hold, that wounds under antiseptic management will heal without suppuration, hence a disregard of this system renders us guilty of wilful negligence, and we are therefore liable for damages.

In the treatment of wounds it is necessary to adopt some kind of a plan, in order to procure the best results, and while it is not necessary to use the cumbersome Lister spray, or to use so many different antiseptics, it is desirable to have a few on hand, in order to meet any cases of emergency. A few antiseptic tablets, antiseptic powders, a bottle of carbolic acid and iodoform, are really the only antiseptics needed. In addition we need aseptic catgut or iron dyed silk for ligatures or sutures, absorbent cotton, antiseptic gauze, rubber adhesive, assorted tubes for drainage and a few roller bandages. The antiseptic tablets (Sharpe and Dohme) are composed of bichloride of mercury 7.3, and ammon-chloride 7.7. Dissolved in a pint of water we have a solution of 1–1000 for cleansing the skin before operating. For small sores we use 1–3000, for larger wounds, 1–10,000, and for large joints, or the peritoneal cavity, 1–21,000. This is the most powerful germicide known. Antiseptic powders are composed of boracic acid, gr. jss, and salicylic acid, gr. xvj each. Dissolved in a pint of warm water, we have Thiersch's solution, which is milder than either the bichloride or carbolic solution. The rule is, the less irritation consistent with a thorough germicidal treatment, the better will be the chance of primary union.

Carbolic acid is also an effective germicide in 1–500. For surgical purposes we use 1–30 or 1–40. Iodoform is used as a dressing.

The application of antisepsis to a proper management of wounds depend upon wounds themselves. Small incised wounds require first, to check the hæmorrhage. If the vessels are of small size, torsion will suffice; if of larger size a ligature will be needed. Should hæmorrhage, however, have ceased, then we proceed to cleanse the surface by allowing a gentle stream of warm Thiersch's, or a weak carbolic, solution to fall upon the wound, either from a sponge or a fountain syringe. Particles of dirt or sand may be removed with forceps or a small pledget of absorbent cotton, previously dipped in an antiseptic solution. After thoroughly cleansing the wound, we dry the same with absorbent cotton, approximate the edges closely, and introduce our stitches. In this kind of wounds we do not anticipate suppuration, therefore drainage will not be necessary. After the surface has been dried, we dust iodoform all over the line of incision and wash off the excess. In a few minutes this line is covered by a crust of iodoform, which is insoluble in water. No other dressing is needed. In a few days raise the edge of the crust, cut your stitches, remove the crust, and your wound is healed. In amputations or other large operations, however, it requires three basinsfull of bichloride solution; one for sponges, one for ligatures and sutures, and the third for the purpose of continued irrigation, before, during and after the operation. Instruments require a carbolic solution 1-40 to render them aseptic. After drying the surfaces and introducing the necessary stitches, dust iodoform all over the line of incision, and begin to dress the stump by applying a silk protective over the wound, and as long as it remains green the wound is aseptic, but as soon as it changes to black it has become septic. Most surgeons, however, have discarded the protective and proceed to apply 5 to 8 layers of antiseptic gauze moistened with the antiseptic solution. The gauze then is covered carefully by a piece of rubber tissue, thoroughly immersed and disinfected in the bichloride solution. Some prefer either oiled silk or mackintosh cloth, but anyway the tissue or any of them should overlap the gauze by several inches on all sides. The

whole is held in position by a few turns of a roller bandage, and this dressing may be left untouched for several days. The thermometer forms a very valuable guide as to the time of changing the dressing. A rise of temperature of 101° is an indication to change, whether the patient complains or not. After the first dressing has been removed, we proceed to thoroughly irrigate with the antiseptic solution as before, and to apply another dressing similar to the first. Where we expect more or less necrosis, however, we must provide for its removal by means of aseptic drainage tubes. They should be brought out at the most dependent part; holes are cut in the strip of antiseptic gauze for the ends of the drainage tubes to pass through. When to remove these tubes depends upon circumstances, from a few hours to three or four days and even longer.

While the above named antiseptics will prevent suppuration, we possess another agent, which will not only sterilize a suppurating wound but will also stop suppuration abruptly. Peroxide of hydrogen ($H_2 O_2$) will pursue pus through the most tortuous passages into the remotest recesses and destroy pyogenic and other micro-organisms. I have employed a 15 vol. solution (Mallinckrodt, St. Louis) in carbuncles, bone felons, etc., very successfully by injecting the cavities with a small glass or rubber syringe, waiting until the foaming ceases and injecting again until the solution fails to bubble. I then apply an antiseptic dressing. The peroxide has been used by others with success in abscesses of the brain and breast, ozæna, gonorrhœa and other suppurating cavities. A close contact with metals, however, will decompose the peroxide.

I sincerely trust that the short method of treating wounds antiseptically, described in this paper will be found not only easy of application, but will, also, by observing results, prove efficient in the management of wounds.

EMPLOYMENT OF PILOCARPINE MURIATE IN LABYRINTHINE DISEASE, WITH REPORT OF CASES. *

BY S. MACCUEN SMITH, M. D.

PHILADELPHIA.

Our object in calling attention to the following interesting cases is, as far as possible, to determine the diseases in which pilocarpine may be of decided benefit, and, if possible, to add to its sphere of usefulness.

Case I.—Mr. F. W., of New Jersey, twenty years of age, has been a bright scholar until within the last two years, when, on account of progressive loss of hearing, he was compelled to leave school and seek medical aid. From a critical examination of the patient, and also of his parents, the personal and family history were pronounced unusually good. The father gave positive assurance of being entirely exempt from any previous specific history, and certainly observation would substantiate his statement, as his entire family of seven children showed impressive evidence of good health.

The patient stated that he had been under treatment for three years with several specialists in neighboring cities, only to meet with discouragement, as his hearing continued to grow worse.

On examination the external ear and canal were found to be normal; membrane tympani slightly opaque and retracted, otherwise normal, except some inflammation the extent of the manubrium mallei. In the post-nasal space the pharyngeal tonsils were found to be much enlarged, the hypertrophy extending beyond and occluding each Eustachian tube. Very low notes of both ærial and osseous conduction of sound were perceived in each ear—the higher notes not being heard except when intense—which would seem to prove that the internal ear was at fault; and as the voice could be heard much better than the watch-tick, this would offer additional evidence of internal ear disease. By my watch, which measures fifty inches, the hearing distance of R. E. $=\frac{1}{1}$; of L. E.=quite negative; and yet ordinary conversation from the bass voice could be heard at six feet, but individual words could not be distinguished until the sound-wave was intensified.

By removing the enlarged tonsils and post-nasal adenoid growths, the hearing power was somewhat increased by equalizing the atmospheric pressure, and thus to an extent correcting the retracted condition of the membrana tympani. Knowing this patient to have been under special treatment for some time, and that the usual methods of procedure had failed to give relief, we deemed a repetition of the same to be a useless experiment, and therefore concluded to place him under the pilocarpine muriate treatment, by hypodermic injections. As the object of such treatment is to produce profuse diaphoresis, the dose to be employed must be in accordance with individual idiosyncrasy. It

* Read before the Philadelphia County Medical Society, June 24, 1891.

has been our custom to commence with a small dose, one-sixteenth to one-eighth grain, and gradually increase, until the full physiological effects of the drug are produced, provided contra-indications (*to be determined by previous careful examination*) do not manifest themselves.

The dose usually employed is one-sixth grain, although one-fourth grain is frequently necessary. In view of the danger to life that is possible to occur in administering full doses of pilocarpine, Dr. Lawrence Turnbull and other authors, advise the use of atropine or strychnine in conjunction with pilocarpine. This is certainly a proper and safe precaution, and should be employed in selected cases; yet, in the greater number of cases, the writer does not find this essential.

As patients cannot usually stand the daily injection, it is our custom to administer one hypodermic every second day; always *insisting* on the patient remaining in *bed* from three to five hours after each treatment, as the perspiration continues for that length of time, and any undue exposure or exertion may produce unfavorable symptoms. These hypodermics are continued until five, eight, or ten have been given, and, if additional ones are required, they may be administered at intervals of five to ten days, at the symptoms indicated.

We will now relate the treatment and improvement of the case in question, the details of which are purposely given, as they are intended to express in main the general treatment and improvement of the subsequent cases; the points of difference, however, will be mentioned in each case.

February 2, 1889, we gave the above case the first hypodermic of one-eighth grain (the hearing distance, you will remember, was R. E. $\frac{1}{L}$, L. E. negative); next day patient thought tinnitus was much less severe; no improvement in hearing; perspiration not profuse. February 4th, gave hypodermic of one-sixth grain, which caused copious diaphoresis, some nausea, and headache. During that evening patient heard wagons passing his window, but could not hear the music from some stringed instruments only fifteen or twenty feet away; his hearing for conversation had materially increased; tinnitus about the same watch-tick, R. E. $\frac{2}{L}$, L. E. $\frac{4}{L}$. It is interesting to note the marked improvement in left ear, which up to this time had been negative.

6*th*. We repeated hypodermic injections of one-sixth grain, as we found this to produce full physiological effect; perspiration about the same; absence of nausea and headache. The next day patient called and stated his hearing had never been so bad, he being unable to hear anything except very intense *high* notes; he was, therefore, much discouraged; all his previous hopefulness having vanished, he refused to submit to further treatment. However, he called the following day and informed me he would continue treatment, as "he thought nothing could possibly make him worse." The peculiar effects of this last hypodermic were the almost entire loss of hearing and the change to perceiving *only high* notes.

8*th*. One-sixth grain was again given, which resulted in the hearing being restored to R. E. $\frac{3}{L}$, L. E. $\frac{3}{L}$; tinnitus almost gone; feeling much better in general health and spirits.

10*th* and 12*th*. He received one-sixth grain, with marked improvement in hearing; R. E. $\frac{9}{L}$, L. E. $\frac{11}{L}$; no tinnitus; general health continues to improve.

At this date patient's father called to be treated for "some fever blisters on tongue and throat," which, on examination, presented such questionable appearances that I, without hesitation, pronounced them syphilitic. He then admitted having had a chancre when twenty years old (his age at this writing being forty-nine). His excuse for previous false statements was, that every physician whom his son had heretofore consulted questioned his family history, and a confession on the part of the father invariably resulted in the son being put on large increasing doses of iodide of potassium and mercury, which so impaired his health that the treatment was discontinued; and as his son had never improved under such medicament, he concluded to conceal his family history, with the hope that other methods of treatment might be pursued.

Granting that the patient's impairment of hearing was specific in origin, in view of his marked improvement I thought it wise to continue with the pilocarpine treatment, in order to more thoroughly establish its efficiency in this class of cases.

The hypodermics were continued on February 12th and every second day thereafter, until eight had been given, at which time his hearing distance was, R. E. $\frac{26}{L}$, L. E. $\frac{32}{L}$; general health improving daily; his weight had increased seven pounds; tinnitus aurium entirely gone.

21*st*. The patient returned home, feeling that he had entirely recovered; but in two weeks he called again at my office with hear-

ing somewhat impaired—R. E. $\frac{22}{L}$, L. E. $\frac{26}{L}$—which he thought came from "catching cold," due to exposure. I again gave him three hypodermics, his hearing increasing to R. E. $\frac{36}{L}$, L. E. $\frac{39}{L}$. Additional hypodermics did not improve the hearing. Thinking he required some *specific* treatment, and remembering that iodide of potassium and mercury could not be tolerated by his stomach, I prescribed Hostelley's syrup of hydriodic acid in two-drachm doses, four times a day, well diluted in water; also inunctions of one drachm of ung. hydrarg. each night and morning. This treatment was continued for six months without experiencing any inconvenience, his hearing remaining about the same; no tinnitus; general health better than ever before, and at this writing—about fifteen months since beginning treatment—his hearing and general condition continue to be good, although the patient has not been taking any medicine for the past nine months.

Case II.—Mr. S. G., of Pennsylvania, aged seventy-one years, consulted the writer, with his family physician, July 8, 1888, and gave the following history: On January 6th of the same year, when arising at his usual hour, he was much alarmed at not hearing the customary noise on the street; thinking, however, that his servant had by mistake awakened him at too early an hour, he consulted his watch, and, on finding the hour rather later than usual, and as everything appeared distressingly quiet, he realized that his hearing had been entirely lost during the night. This complete loss of hearing was not attended with pain, tinnitus aurium, discharge from the ears, nor inconvenience of any kind.

After being under treatment for three months, and not receiving the slightest benefit, while drinking some hot milk by the direction of his physician, he was seized with intense tinnitus aurium, vertigo, and constant emesis *without nausea*, but with entire absence of pain. The emesis continued for only three hours, but the tinnitus and vertigo increased in severity.

In this condition the patient consulted the writer. A more despondent and pitiable mortal could not be imagined. He was not able to walk without assistance, and the tinnitus had prevented sleep for almost two weeks. The membrana tympani and the external auditory canal were normal, excepting the changes peculiar to a person of his years; the post-nasal space including the Eustachian tubes, was in good condition; in brief, both ears and their appendages presented the usual normal condition in so far as observation alone could determine. In this connection it is interesting to note the entire absence of evidence of disease in such cases. Osseous conduction of sound was well marked, especially in the left ear; aëreal conduction of sound was quite lost in both ears.

The family physician informed me that his patient had been on large increasing doses of iodide of potassium and mercury, but the stomach would no longer retain the potassium iodide.

We subjected this patient to the pilocarpine treatment, as previously described, with the following results: First treatment resulted in slight decrease in vertigo and tinnitus, but hearing power remains the same; caused some temporary vomiting, which was quite severe for two hours. The second and third hypodermics were given without any appreciable benefit; the fourth and fifth, however, were productive of marked improvement in vertigo and tinnitus, and at the same time caused such changes in the perceptive organs of hearing that he was able to hear intense waves of sound. After the sixth treatment tinnitus and vertigo had almost ceased, and hearing distance increased to $\frac{1}{L}$ in both ears. The seventh and eighth treatments did not produce much change in hearing distance, but entirely relieved vertigo and tinnitus. The nineth hypodermic caused much improvement in hearing: R. E.=$\frac{9}{L}$, L. E.=$\frac{11}{L}$.

The patient found it necessary to return home, and I directed his family physician to continue the treatment until four additional hypodermics had been given, at the end of which time patient called, with this marked improvement: R. E.=$\frac{21}{L}$, L. E.=$\frac{27}{L}$. The patient's business called him to the far West, and required his being away for four months. I gave him Hostelley's syrup of hydriodic acid to take during his absence. On his return the condition of hearing was almost normal, and remains the same at this writing.

As the details of a large number of such cases would consume much time and space, and withal prove tiresome, the object of this paper will have been accomplished by briefly stating that the writer has treated forty-seven cases of greater or less impairment of hearing—some amounting to almost entire deafness—by the method of hypodermic injections of pilocarpine muriate; and that

from his observations in these cases he feels justified in expressing the following conclusions:

That age and sex have no influence on the success or failure of treatment.

That in recently developed deafness with tinnitus this treatment is much more hopeful of success than in cases of longer duration. In one case, however, which was of specific origin, the patient, aged seventy-two years, had been almost deaf for twenty-two years, and yet this was one of the most successful cases treated. Nevertheless, this must be considered as very exceptional.

That cases of chronic suppurative otitis media with some degree of impaired hearing, resulting from the exanthematous fevers, are not proper cases to receive benefit from this method of treatment.

That deafness, vertigo, and tinnitus arising from syphilis seem to be especially benefited by the subcutaneous injection of pilocarpine.

That these results can only be attained by pushing the pilocarpine to its full physiological effect, and that profuse diaphoresis must be obtained in every case.

Paris Letter.

Partial Nephrectomy, Extirpation by Dissection of a Large Cyst of the Kidney, by M. Tuffier.

In the following case reported by the above named surgeon we have union by first intention, of the renal parenchyma in the midst of the urinary liquid, thus proving the possibility of removing benign tumors of the kidney without destroying the function of the organ in question.

In the case of a serous cyst of the kidney, complete nephrectomy or drainage of the tumor is the usual resort. M. Tuffier states that the first method is dangerous, as out of twenty-four (24) operations 11 terminated fatally (45 per cent). The second method is incomplete, as in eight (8) operations, four (4) were followed by persistent fistulæ (50 per cent.,) necessitating a secondary nephrectomy. M. Tuffier's method supported by numerous operations, consists in radically extirpating the tumor, and preserving the kidney. He reports the following case: "A man sixty-four years of age employed in commercial business sought advice in consequence of hæmaturia. The patient entered Beaujon Hospital. The hæmaturia was of twelve months duration, with variable intensity, and accompanied by an exaggerated desire to urinate. The urine was blackish in color, contained some clots, indication of a notable loss of blood, which explained the anæmic condition of the patient. Careful examination of bladder resulted in diagnosis of neoplasm of that organ. Examination by the rectum was negative, and cystoscopy was impracticable. Upon palpation the kidney was found enlarged to the size of head of a fœtus. On the 9th of February I made an incision in the lumbar region. Upon exploration the body of the kidney was found to be normal, the upper extremity presented a prolongation, reaching to a point under the diaphragm, forming a tumor about the size of the fist. This was slowly uncovered, and brought into the field of operation by swinging it behind the 12th rib. I discovered that I had to deal with a large renal cyst, the transparency of which was complete. It occupied only the upper third of the organ, the rest of the gland presenting no alteration. I decided to extirpate the cyst by dissection. An assistant pressed upon the renal pedicle, while I dissected the cyst throughout the parenchyma. I removed in this manner the entire tumor without loss of blood. The opening was closed by passing fine cat-gut sutures through the lips of wound.

"Pressure was now removed from the pedicle. There was no oozing of blood. The kidney was replaced and abandoned in its lumbar abode. The muscles and aponeurosis were sutured in layers, and the skin was brought together by means of horse-hair, without drainage. On the seventh day the horse-hair was removed, and all was ended, as far as the wound was concerned. The hæmaturia continued and I extirpated, twenty days later, a neoplasm of the bladder, by supra-pubic incision. My patient is now well."

The results of nephrectomy or complete extirpation of the kidney, first practised by Wolcott in 1861, and later by Simon of Heidelburg, has not been encouraging, therefore this method by dissection seems to me susceptible of application to the vast majority of benign tumors of the kidney.

Lucia Redding Thompson, M. D.,
Paris, France.

Selected Formulæ.

PILOCARPINE IN GLAUCOMA.

Drs. Saint-Germain and Valude (*L'Union Med.*) recommend the following:

℞

Pilocarpini.....grs. ivss.
Aq. destil.....f ℥ijss.
M. ft. collyrium.

This collyrium is employed alone, or in alternation with a solution of eserine, in glaucomatous conditions of children, when eserine does not agree with the patient.—*The Prescription.*

TREATMENT OF SIMPLE CHANCRE.

In the *Revue Générale de Clinique et de Thérapeutique*, Castel, after pointing out that the danger of this lesion resides in great part in its virulence and in the facility with which re-inoculation is possible, proceeds to consider the best application for its relief. After reminding us of the fact that Ricord habitually employed the charcoal and sulphuric acid treatment for this purpose, and obtained from its use very extraordinary results, he draws attention to the more recent methods of treating the disease, also calling attention to the use of Canquoin's paste. Diday and Fournier recommend the employment of a solution of nitrate of silver, and the latter has found that the application of a 3 per cent. solution produces very excellent results. The lesions should be dressed with a tampon of absorbent cotton dipped in this solution and renewed three times a day. With this treatment simple chancre should be cured in from three to six weeks, and it may be advisable to apply not only antiseptic washes, but oxygen water and solutions of chloral or Labarraque's solution. According to Rollet and Mauriac the following applications are also very useful:

℞

Water..... 6 drachms.
Lemon-juice ..... 1½ "
Laudanum..... 45 minims.
Goulard's extract..... 1 drachm. M.

Or,

℞

Water..... 1 ounce.
Citric acid..... 45 grains.
Hydrochloric acid..... 45 "
Perchloride of iron..... 45 " M.

ATROPINE IN URINARY INCONTINENCE OF CHILDREN.

℞

Atropin. sulphat.....gr j.
Aq. distillat.....f ℥j.
M. Sig. Give as many drops as the child is years of age at 4 and 7 o'clock P. M.

—*Therapeutische Monatshefte.*

ANTHELMINTIC.

Iméré recommends the following for children from six to twelve years of age:

℞

Ethereal extract male fern.....gr. xlv.
Syrup Calomel.....gr. iijss.
Distilled water.....f ℥ iv.
Powdered gum arabic..... ℥ ss.

M. S.—To be taken at one dose. Milk diet should be given the preceding day. The worm is usually expelled in from thirty to forty minutes.—*Le Progrès Médicale.*

OINTMENT FOR HÆMORRHOIDS.

Audhoui recommends, in *L'Union Médicale*, the following ointment for hæmorrhoids:

℞

Extract of belladonna.....15 grains.
Extract of thebaia.....15 "
Antipyrin.....45 "
Mercury ointment.....2¼ drachms.
Simple cerate.....1 ounce.

This is to be made into an ointment and applied to the inflamed hæmorrhoids. Rectal injections of warm water are to be employed if constipation is present.—*Medical News.*

FOR THE GRIPPE.

Dr. E. R. Palmer, in a recent number of the *Prac. and News*, says: With the recurring prevalence of the so-called grippe, I beg leave to suggest the following as a specific for adults in such cases:

℞

Salol.....℈ iij.
Phenacetin..... ℈ ij.
Quiniæ salicylat..... ℈ j.
M. Ft. cap. xx. Sig. Two every three hours.

AN EXCELLENT COUGH MIXTURE.

℞

Ammonii hydrochlorate..... ℥ iij.
Morphina sulph.....gr. iij.
Potassii cyanidi.....gr. ij.
Syr. pruni virginiani
Syr. tolu.....aa..... f ℥ iij.
Syr. scillae..... f ℥ ij.
Aquæ q. s. ad..... f ℥ xij.
M.

Dissolve muriate ammonia, morphine and potash separately in the water and add other ingredients.

Sig. Tablespoonful when necessary, to relieve cough.

The above prescription I have found particularly efficacious in coughs of bronchitis, acute or chronic, affording relief when many other remedies had failed.—*Dixie Doctor.*

GALACTORRHŒA.

℞

Potassii iodidi. gm..... ℥ss.
Syrup raspberry " ..... f ℥v.
Aquæ dist. " ..... f ℥jv.
M. Sig. f ℥ss. three times daily.

—*Braun, L'Union Médicale.*

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

EDWARD T. REICHERT, M. D.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF PENNA.,
EDITOR AND MANAGER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

THE MEDICAL AND SURGICAL REPORTER.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent 3 months on trial for $1.

At the termination of the period of subscription, we will promptly discontinue sending THE REPORTER unless directed to the contrary by the subscriber.

Remittances should be made by draft, check, postal note, or money order payable to Edward T. Reichert.

THE POCKET RECORD AND VISITING LIST.

Two sizes. Prices to subscribers of THE REPORTER: For 30 patients a week (with or without dates), $1.00. For 60 patients a week (without dates), . . $1.25. Prices to non-subscribers, $1.25 and $1.50 respectively.

THE MODEL LEDGER.

Physicians who keep their own books will find this of great value. Sample pages sent on application. Price, $5.00.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If THE REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS.

Write in ink.

Write on one side of paper only.

Write on foolscap or legalcap paper.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be pleased to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

LEADING ARTICLE.

THE TREATMENT OF TYPHOID FEVER BY COLD WATER BATHS—OR THE METHOD OF BRAND.

Although this mode of treating typhoid fever has recently attracted considerable attention in this country, it is surprising that in consideration of the favorable results reported, it has not been more widely adopted in private as well as in Hospital practice. However, when we consider the multitude of worthless therapeutic suggestions which fill the columns of medical literature, we are forced to admit that conservatism regarding new methods of treatment is rather to be commended. In the present instance, however, it would appear that because of certain very popular and deeply rooted antipathies to this form of therapeusis, there is danger of its careless or insufficient trial by a large portion of the profession. These objections chiefly are the inconvenience attending its use in private cases, and the alarming symptoms which occasionally arise directly from the cold bath, together with a feeling of distrust of the statistics which prove its usefulness. The last objection is so groundless since observations have multiplied so richly, that it needs no comment. On the contrary, the first two objections are practical ones, and it cannot be denied that in private practice, such treatment will often meet with disfavor from the patient and his friends, or that apparently alarming symptoms do, at times, not follow the cold bath. But the test of the value of the treatment is certainly the effect which it has upon the mortality and course of the disease, and the proof already accumulated in its favor is indisputable.

It is the duty of the medical profession to mould public opinion to views consistent with our positive knowledge of the subject, and when this is wisely done, generally it will be found that popular prejudice will rapidly disappear. In very many instances it will be found that the patient strenously objects to the disagreeable exertion required in the exercise of the bath, and only a wise

firmness on the part of the physician and attendants, will enable the faithful performance of the treatment. These are the purely practical objections which have to be overcome. Theoretically, the method of Brand is opposed to our old ideas of the treatment of typhoid fever. The movement and exertion required of the patient is totally at variance with common practice, and at first sight it seems actually cruel to so disturb the sufferer; but, taking into account the results obtained, there can be no doubt that the duty of the profession is to give it a fair trial.

For the benefit of those who may not be perfectly familiar with the method of Brand we quote the following description of it from an excellent paper: ("The treatment of enteric fever, with special reference to the method of Brand," by J. C. Wilson, M. D., Physician to the Jefferson College Hospital and the German Hospital, Phila. Read before the Lycoming county Medical Society, Williamsport, Pa. Nov. 4th, 1890. *Med. News*, Dec. 6th, 1890) by Dr. J. C. Wilson, of Phila. He says: Whenever the temperature taken in the rectum reaches 103.2° F. (39° C.) the patient is placed in a bath of 65° F. A compress, wet with water about five degrees lower, is placed upon the head, or water of a lower temperature is poured upon the head and shoulders. The patient remains in the bath fifteen minutes, during which time he is systematically rubbed by the attendants and encouraged to rub himself. At the expiration of this time he is removed from the bath, and wrapped in a coarse linen sheet over which a blanket is folded, the extremities being thoroughly dried and rubbed. A little wine or spirits is then given. This is repeated every three hours, unless the temperature remains below 102.2° F. The alimentation is liquid, nutritious, and carefully regulated. No drugs are administered."

This briefly and clearly outlines the technique of the treatment, and for a fuller account of the exact application of this systematic remedial procedure, the reader is referred to the complete outline of it, as contained in Dr. Wilson's paper, being quoted from Glenard, (*Le Bulletin Médicale*, Feb. 26, 1888,) who also says: "Alimentation should consist of the following articles: Milk, diluted with coffee or tea or cocoa, (a quarter of a litre at each administration;) thoroughly cooked gruel, oatmeal, tapioca, or vermicelli; veal, mutton, or chicken-broth, freed from fat when cold and re-heated at the moment of administration. As a drink, pure cold water should be given; the indication for wine or spirits is urgent only in cases that are subjected to this treatment late in their course."

Such, then, in brief, is the method of Brand, and so harsh does it appear, when contrasted with our ordinary treatment of typhoid fever, that only the most absolute proof of its beneficient action can convince the novice that it is entirely rational. It presents a most striking contrast to the expectant method of treatment, and to all the other modern modes of dealing with this disease, such as by antipyretic and antiseptic drugs.

What proof is there that the method of Brand is better than these? Since the paper of Dr. J. C. Wilson is the most complete we have seen upon the subject, we will quote, for the benefit of our readers a few of the statistics he has so admirably collected together, conclusively proving the reduction of the Hospital mortality of typhoid fever under the use of the cold water bath. Thus, in the combined number of cases treated in London Hospitals under other modes of treatment than cold water baths, the mortality, from a total of 13,936 cases, was 17.8 per cent., and in 27,031 cases collected by Dr. Murchison, 17.45 per cent. were fatal. Jaccoud found that 19.23 per cent. of 80,140 cases collected from European Hospitals, were fatal. Of 17,000 cases treated in the General Hospital of Vienna, the mortality was 22.5 per cent. In the English army the death rate varies from 24 to 40.7 per cent. Of 307 cases treated at the Mass. General Hospital, 13.5 per cent. died. The death-rate during our late war was 35.9 per cent. among white troops, and 55.6 per cent. among colored troops. In New York Hos-

pitals the mortality from 1877 to 1883 varied from 20.1 to 30 per cent. The foregoing cases were all treated by expectant or symptomatic modes of therapeusis.

Brand collected 19,017 cases treated by cold baths, only 7.8 per cent. of which died; and Vogl's mortality from 1875 to 1881, with 702 cases, was 7.6 per cent., the treatment being baths and internal antipyretics.

Following these are statistics of strict cold water bathing: Tesssier, 139 cases in 1887, with 5 per cent. fatal; Vogl, 420 cases, treated in 1880, 2.7 per cent. fatal; 141 cases from 1882 to 1887 gave 3.5 per cent; Brand, 2,198 cases, all treated by strict cold baths, 1.7 per cent. died, and omitting those not treated before the fifth day, the same figures give 2,150 cases, without a single death.

The above figures, are abstracted from a large number of the statistics found in Dr. J. C. Wilson's paper, certainly give us food for serious thought. The same author gives an interesting table of the mortality in 1889–90, in some of the chief Philadelphia Hospitals, where the cases were treated by expectant, symptomatic or antipyretic remedies, and the mortality varied from 12.5 per cent. in the Episcopal Hospital to 26.6 per cent. in the St. Agnes Hospital. At the Pennsylvania Hospital it was 16.1 per cent., while fifty cases treated by Dr. Wilson, at the German Hospital, gave a mortality of 2 per cent.; ten of these cases were treated with carbolized iodine, and the remaining 40 cases were treated strictly by cold water baths, the only death occurring being one of the number treated by carbolized iodine, so that of 40 consecutive cases treated by the cold water baths, all recovered. Dr. Wilson states that "severe symptoms were mitigated, and mild cases ran a most favorable course," and he also remarks that he modified Brand's method in two particulars: (1) "He took the temperature in the mouth instead of in the rectum. (2) Each case admitted prior to the tenth day, received one or two laxative doses of calomel."

Thus, we have seen from the figures quoted, the large degree of confidence which the strict cold bath treatment has inspired in different countries. To read some of the reported experiences, one would almost be inclined to the belief that it should always be adopted in any stage of the disease or condition of the patient. But the indication from available statistics, is, that the best results follow its early use in sthenic cases of the disease. There seems every reason for avoiding its use in the cases where the patient is not seen until the second or third week of the disease, and not even the brilliant array of statistics can yet convince us, that it is a wise procedure when there are grave pulmonary, cardiac or renal complications. Given a case in the third week of typhoid fever, with unusually deep ulcers almost ready to perforate, the conclusion is inevitable that the *strictly applied* system of Brand would be a dangerous treatment.

Any new treatment of undoubted value is universally too widely and indiscriminately applied without sufficient attention being paid to the selection of proper cases, and no doubt the proper limitations will after a while be found, within which this system of practice can safely be used. The inclination to doubt statistics is not without some reason when it is remembered that they rise and fall considerably in different periods, without reference to the treatment employed. From 1868 to 1882, in the Hospitals of Paris, the mortality was 21 per cent., from 1882 to 1888 it fell to 13 per cent., and in 1889 it rose to 14 per cent., irrespective of the mode of treatment. (Merklem, "The treatments and the mortality of typhoid fever in the Hospitals of Paris," *Bull. et. Mem. de. la. Loe. des Hosp.*, July 9th, 1890, p. 628.) Also, there is a marked difference in the two sexes, the mortality for women being higher.

While Dujardin-Beaumetz speaks in favor of the cold bath, (*Therapeut. Gaz.*, January 15th, 1891,) he prefers in his own Hospital practice, lotions, wet packs and tepid baths, and claims as good results as are obtained from the strict system of Brand. He further says: "I am a thorough opponent of systematization * * * For a disease

like typhoid fever, which presents itself under the most variable forms, we cannot admit a therapeutic formulæ which applies indiscriminately to all cases, and our treatment should vary according to the patient we have before us." The same eminent authority says: "I obtain with these tepid baths sedations of the nervous disturbances a sufficient fall of temperature, a state of freshness of the skin and general comfort, which enables the patient to get the needed rest." (*Ther. Gaz.*, January, 1890.)

Other papers giving very favorable testimony regarding the therapeutic value of cold baths in typhoid fever are available, and we might especially mention several of interest, including one by Dr. Sihler (*Cleveland Med. Gaz.*, 1890, VI., p. 193–208,) and two others, (*Jour. Am. Med. Assoc.*, 1891, XVI., 369, and *Practitioner, Lond.*, 1891, XLVI., 161–184,) but as they contain the same sort of evidence we have already referred to, we will leave their perusal to the interested reader.

While, from the evidence before us, the method of Brand has apparently lowered the mortality of typhoid fever more than any other single mode of treatment which we are aware of, still repeated experiences with it are in order so as to establish its exact value, and the best way of application of the cold water. So many conditions influence the course, duration and death-rate in this disease, (such as climate, season, and the physical and social status of the patient) that more statistics of undoubted veracity are needed to help us decide wisely regarding its true value. From the most encouraging reports which have followed the use of antiseptics in this disease, especially with the idea of influencing local conditions of the intestines which mitigate against the patient, we should think, that the combination of the local antiseptic treatment with the method of Brand should yield good results. If it is proven that the action of *cold* abolishes all those general symptoms referable to conditions of the nervous and vascular systems, under the stress of the bacillus of Eberth; and if it is equally proven that the maintainence of intestinal antisepsis removes all those dangerous local symptoms more effectually than other modes of medication, is not the inference that a combination of these two therapeutic measures would enhance their separate value, a natural one? However enticing such a theory may be, we are inclined to agree with Professor Dujardin–Beaumetz when he says in effect that any iron-clad system of treating typhoid fever is impossible, and that just as the disease now presents one indication and anon another more or less different and important, so should our remedies differ as we appreciate the demand of each case. The addition of the application of higher degrees of cold, than we have used for many years, is undoubtedly an advantage, but it will be a greater one when we know exactly how and why cold does good, and, therefore, be better prepared to wisely administer it.

Finally, we would bespeak for the cold bath treatment the earnest consideration, and the careful trial, which the importance of the subject demands. The saving of ever so few lives in every hundred cases means many thousands of lives of use to the world, and it is to be hoped that the system of Brand, if not perfection itself, will at least aid us to know more perfectly to what extent cold can favorably influence the course, duration, sequelæ and mortality of typhoid fever.

CORRESPONDENCE.

CLEANLINESS IN SURGICAL OPERATIONS.

(*Correspondence between Dr. Hiram Corson, of Plymouth Meeting, Pa., and R. Stansbury Sutton, of Pittsburgh, Pa.*

PLYMOUTH MEETING, 7–8–91.

DEAR DOCTOR SUTTON:

Thanks for your pamphlet, on "The Importance of Cleanliness in Surgical Operations." I have carefully read it. The profession is much indebted to you; for you were one of the first to show that it was not the carbolic spray that was the preventive of danger and death in abdominal operations—but that cleanliness was the essential. I have much pleasure in believing that the surgeons in America are as skilful and suc-

cessful as any others in any country; and since the issue of your paper years ago, have held you up as one who could reach success without other antiseptics than the cleanliness obtainable by the use of simple unmedicated water—but I have been confronted by the fact, urged against me, that you carbolized your instruments—I have regretted, and still do, that you did not try what could be done with merely using water in which to lay your instruments and for all other purposes. I feel sure that you would have been equally successful. On p. 8, speaking of Prof. Schröder, you intimate very plainly that the hazard of his operations is greatly lessened by the fact that "the peritoneum is but little exposed to the spray." But why did you not add, in your facile way of putting things, that he ought not to *endanger* his patients by even a weak spray. Don't you believe that any use of the antiseptics in contact with the peritoneum is dangerous? You do not, for on p. 9, you say, that "where hospital surroundings are not pure, it will be well to follow the antiseptic method." You do not doubt Lawson Tait—but do not go so far. I wish you would try cleanliness and nothing else. But on p. 10, you say: "There *are* many surgeons who no longer use Listerism." Why then use it at all? You properly give Lister credit for doing that which led to cleanliness, and I never wish to lessen in the least the honor accorded to him, but you admit that death has been caused by some of the antiseptics, but never by cleanliness. Would it not be safer to have the ligatures "submerged" in water, than in "a five per cent. carbolic acid?" The ligature touches the peritoneum. "In Europe, Listerism and cleanliness accompanying it, is seen everywhere." But do you think it necessary? Almost, No—I wish you could no without the *almost*.

We owe you much my Dear Doctor, but I do want you to put us under still further and greater obligations by proving to the world that cleanliness—the cleanliness that can be obtained by the use of water—is safer than cleanliness and Listerism combined. You have, doubtless, seen my paper on "Antiseptics in Mid-wifery." It is a paper that was written for our Society—the County Society—and without any expectation that it would go further. I could have made it stronger perhaps, but I am so old and forgetful now, that I ought not to write at all, not even this letter. If you have not seen it I will send a copy. I shall be most happy to read whatever may hereafter fall from your graceful pen. With kindest regards, sincerely your friend.

HIRAM CORSON,
Plymouth Meeting P. O., Pa.

PITTSBURGH, PA., July 11, 1891.

My Dear Dr. Corson:—Your kind letter of the 7th inst. is to hand. It was with great interest that I read your paper on "Antiseptics in Midwifery" in a recent journal. Facts are stronger than theories. In your letter just received, commenting upon my paper, "Importance of Cleanliness in Surgical Operations" read before the American Gynæcological Society at their meeting eight years ago this Autumn, you say that you have been confronted with the fact that "you carbolized your instruments." To assure you of that support, which you fear is not to be found, in my practice with reference to carbolic acid, I am glad to say, that for *eight years no carbolic spray has been used over any wound which I have made. No carbolic acid or other chemical has been used in the water covering my instruments, during operation, or been introduced into the sponge, water or overhead flushing bag during the same period. I have not carbolized a ligature for five years. The last carbolized ligature which I placed upon a pedicle came through the abdominal wall three months after the operation; it had been boiled in a five per cent. solution.* Eight years of constant experience have elapsed since I wrote my paper. Now I can say, that I know of no chemical solution which can fail to be injurious if introduced into the cavity of the abdomen, and that pure water at a moderate temperature is all that is required. After I close an abdominal wound I put on a top dressing of thymol or iodoform gauze, first having sponged off the surrounding skin with 1–2000 mercuric solution. Pin on a bandage and let it go for a week. Probably this chemical top dressing is not needed, but gauzes are clean and aseptic. The chemical is outside of the body, *where it ought to be*, and simply guards the open gate way. In total extirpations of the uterus I have deviated from my habit in abdominal sections. In the total extirpations, I have operated with the patient on her back, the trunk of her body, above the pelvis, elevated, and the pelvis still *further set on end* by a roll three inches in diameter placed under the small of her back. During the extirpation, a stream of 1–5000 mercuric solution has been playing into the vagina, and after the operation was completed an iodoform tampon has been put into the

vagina. In this position no fluid runs upward into the peritoneal cavity. But I should have said that in my last total extirpation the solution was 1–10,000. Do you observe, my dear doctor, the tendency to get rid of the chemicals here also? I will do it. The Listerian technique so far as it pertains to chemicals is abandoned, so far as it presages the importance of cleanliness it is retained, in my work, with the exception referred to. The results obtained in abdominal surgery under this seclusion of the Listerian technique have been good, by far the best ever obtained by any other operator in this city.

My institution, Terrace Bank Sanitorium, has just completed its eighth (8) year. It will reopen September 1st. With kind regards, and the hope extended that you may be spared to see the bacillus, only the little tail of pathology, made less of,

I am sincerely your friend,

R. Stansbury Sutton.

Book Reviews.

PHILADELPHIA HOSPITAL REPORTS. Volume 1. Edited by Charles K. Mills, M. D., Member of the Neurological Staff, Philadelphia, 1890.

We hail with pleasure the appearance of this, the first volume of the Philadelphia Hospital Reports. In an institution of such magnitude as Blockley, with a staff of physicians, surgeons, obstetricians, neurologists, optholmologists, dermatologists, pathologists, bacteriologists, etc.; each member of which, is an authority upon his special branch, the opportunity for valuable clinical study cannot be overestimated, and it is important for three reasons that such work shall be recorded in annual reports. In the first place, it encourages the members of a medical board to do more scientific work and study; secondly, the profession at large, is benefited by the experience gleaned from the pages of such a volume, and finally, the Hospital's interests are advanced both by the better records made and the wider knowledge given the public of the institution's work.

Abroad it is the general custom for the large Hospitals to publish annual reports, and the published volumes are replete with useful knowledge and with statistical and other papers, which have been quoted over and over again in medical works of the highest standard.

In the present initial volume of these reports, considerable space has been devoted to the history of the Hospital. Contributions in this line are furnished from such well-known writers as: Dr. D. Hayes Agnew, Dr. Alfred Stillé, or Lewis P. Bush, Dr. Chas. K. Mills and Dr. Roland G. Curtin. Valuable papers have been furnished by:

Drs. Roland G. Curtin, James B. Walker, J. H. Musser, F. P. Henry, W. E. Hughes, J. M. Anders, S. Solis Cohen, Wm. G. Porter, John B. Deaver, Ernest Laplace, E. E. Montgomery, Clara Marshall, Barton Cooke Hirsh, Edward P. Davis, Henry F. Formad, J. L. Hatch, Chas. K. Mills, F. X. Dercum, W. J. Hearn, Wharton Sinkler, T. J. Harris, C. S. Bradfute, J. H. Lloyd, A. J. Smith and G. E. de Schweinitz.

An interesting contribution from Dr. Roland G. Curtin is worthy of special note as bearing upon the history of epidemic diseases. It is entitled "Epidemics in the Philadelphia Hospital from 1862 to 1890."

The book is illustrated.

We earnestly hope that the Philadelphia Hospital authorities will continue the good work, so auspiciously begun, from year to year and we further wish that the example thus set, may soon be followed by the other large Hospitals in the United States.

THE MODERN ANTIPYRETICS: THEIR ACTION IN HEALTH AND DISEASE. By Isaac Ott, M. D., Easton, Pa.: E. D. Vogel: 1891.

This little *brochure* comprises within its fifty odd pages considerable new and interesting information as to several of the new chemical compounds that are being offered to the profession for their antipyretic value. Within this small compass the author has given a description of his human calorimeter, a study of the calorimetry of malarial fever, some important notes on the chemistry, physiological and pathological action, and on therapeutics of those coal-tar products that are of the class in question, and lastly, an interesting chapter on the "Value of Antithermics in Typhoid Fever."

Dr. Ott says "My experimental researches lead me to believe that fever is due to an agent from within or without, which deranges the harmony of the thermotaxic, thermogenetic and thermolytic apparatuses, by which, in the initial stage the metabolism of the tissues is usually temporarily increased, and this increment is usually greater than that generated upon a restricted amount of nutriment."

Those interested in the study of the relations between body temperature and disease will certainly find the volume highly entertaining, whether they agree with the author in his conclusions or not.

PERISCOPE.

THERAPEUTICS.

THE USE OF COCAINE AS AN ANÆSTHETIC.

At a meeting of the Académie de Mèdecine, on May 12th, the report of the commission appointed to consider M. Hallopeau's communication on cocainism (see supplement, December 13th, 1890, p. 84), was presented by MM. Panas and Magitot (*Bull. de l'Acad. de Méd.*, 3me Série, t. xxv. No. 19). After a review of the literature of the subject—confined almost exclusively to French sources—they cite the experience of M. Paul Reclus, who has performed more than 1,200 operations (removal of tumors, hydrocele, excision and erasion of joints, laparotomy, gastrostomy, strangulated hernia, etc.) without accident. M. Reclus finds that for mucus membranes the application of cocaine to the surface is sufficient, but if more profound anæsthesia is required it should be injected, not hypodermically, but intradermically. Care must be taken not to inject any of the drug into a vein; the injection should be made slowly, the quantity never exceeding 10 centigrammes, this amount being used only for extensive operations, and being administered in a series of injections at different points so as to embrace a wide surface. MM. Panas and Magitot, following in great part the teaching of M. Reclus, sum up their conclusions as follows: (1) Cocaine is an excellent local anæsthetic, which should on no account be banished from surgical practice. (2) It should, however, be used with the following precautions: (*a*) The dose should be proportional to the extent of surface it is desired to render insensitive, but should in no case exceed from 8 to 10 centigrammes; (*b*) cocaine should never be employed in persons suffering from cardiac complaints, chronic affections of the respiratory passages, or well-marked neurotic diathesis; (*c*) it should be injected *into* and not under the mucus membrane and skin; a 2 per cent. solution is the best; it should always be prepared fresh and injected with a sterilized syringe; (*d*) the patient should always be in the recumbent position when the injection is given, even if the head has to be raised afterwards; (*e*) the drug should be of the most absolute purity, and in particular free from any admixture of toxic alkaloids; (*f*) it should be given in divided doses, an interval of some minutes being allowed to elapse after the first injection of the first portion; this will give an opportunity of observing whether any untoward effect is likely to occur. (3) Used in this way cocaine has obvious advantages over chloroform, ether, etc., one of the chief being the possibility of operating without assistance. (4) The anæsthetic effect always lasts long enough to allow of the performance of "all the operations of ordinary surgery." In the discussion which followed the reading of the report M. Constantin Paul spoke of the internal administration of cocaine, pointing out that doses of 15, 20, and even 30 centigrammes could be taken in this way without danger. He said the intradermic injection was very painful. M. Laborde, while admitting that much larger doses could be taken by the mouth than could be safely given hypodermically, and that remarkable analgesic effects could thus be produced in cases of gastralgia, etc., and that he had seen serious accidents from the internal administration of large doses. The conclusions embodied in the report of MM. Panas and Magitot were adopted by the Academy.—*Brit. Medical Journal.*

INHALATIONS IN THE TREATMENT OF PHTHISIS.

The *Lancet* for May 23d says: "The history of inhalations in the treatment of phthisis is not an encouraging one. They have been widely employed and hailed as the most rational and effective mode of assailing the disease at its seat. But the results of this method of medication have not been commensurate with the expectations excited by it, and we imagine that of late it has been gradually falling into disfavor and disuse. Several potent objections have been urged against the method. First, it has been denied that the various antiseptic and germicide agents applied by inhalation succeed even in reaching the seat of the disease—viz., the submucus tissue of the bronchial mucus membrane—but are arrested often in the pharynx, oftener still in the larynx. Then it has been shown that, even assuming that the medicated atmosphere produced by one of the ordinary inhalers really reaches the seat of the disease, its impregnation with carbolic acid, creasote, thymol, or other such agent, is so exceedingly feeble as to leave no

solid ground for anticipating serious benefit from its use. Further, many authorities urge with much force that if the phthisical patient be taught to rely upon inhalations the inevitable result will be a life of indoor invalidism and constant tinkering with his inhalers—a mode of existence sure to effect an amount of mischief more than sufficient to counterbalace the problematical advantages of inhalation.

"There is much weight in the above objections, and until they can be satisfactorily met, the place of inhalations in the therapeutics of phthisis can not be an important one. Professor Germain-Sée, in a recent paper presented to the French Academy of Medicine, has sought to overcome the first of the objections to which we have made allusion—viz., the failure of the medicated atmosphere to reach the actual seat of the disease. He recalls the researches made at various times into the action of creosote upon tuberculosis. This drug has had a remarkable and somewhat checkered career. Discovered in 1832 by Reichenbach, its true composition was first made known in 1853 by Gorup-Besanez, who showed that it consisted mainly of two substances—gaïacol and créosol. It was in 1877 that Bouchard and Gimbert conceived the idea of its possible utility in phthisis, and made trial of it both *per primam viam* and hypodermically. Later, Fraenzel and Sommerbrodt in Germany made extensive trial of creasote, and reported benefit from its use. Guttmann, in his researches in the year 1889, found that the saturation of the system with creasote arrested the development of the bacilli, and suggested that the best means of bringing the system thoroughly under the influence of the drug would be to submit the patient to an atmosphere saturated with creasote under pressure. This is also the method recommended by Professor Germain-Sée. He describes it as follows: "The patient is shut up in a metal chamber, hermetically closed, and compressed air, passed through creasote and eucalyptol, is made to enter slowly. The air in passing through these liquids is saturated, and arrives charged with a large quantity of these medicaments. The pressure must be slowly increased, and should not exceed a half-atmosphere. The speed of delivery of the air saturated with the medicated vapors is from fifteen to twenty cubic metres per hour for a space of five cubic metres of capacity. The length of time the patient remains in the chamber is usually two hours, sometimes three or more, and no inconvenience ensues as the result of this proceedure. The inhalations are made daily or more frequently.

"Professor Germain-Sée has tried this method in twelve cases, of which one was a case of apical bronchitis, a second was a case of fœtid bronchitis, and the remaining ten were genuine cases of tubercular phthisis —all of which, with one exception, had arrived at the stage of softening. The results obtained would appear to be surprising, a marked amelioration being in most cases observable, not only in the amount and character of the expectoration, but in the general constitutional condition, and in some cases, though not in all, a corresponding improvement in the physical signs. Contrary to what might seem probable, hæmoptysis was not only not excited, but seemed controlled by this mode of treatment, and the appetite and digestion were improved rather than otherwise. Hectic fever was also diminished. Naturally, the least improvement was manifested in the physical signs, but Professor Germain-Sée is inclined to hope that by this new method the disease, if not cured, may be at least arrested, and further progress prevented. Benefit was obtained in some cases in a fortnight, in others the treatment was kept up for three months. Very great benefit was obtained in some cases of scrofulous enlargement of the cervical glands.

"At the present time it is hardly necessary to emphasize the necessity for extreme caution in admitting the claims of any new alleged remedy for tuberculosis, and the evidence before us in the present case, although interesting, falls immeasurably short of demonstration. Further trials will no doubt be made, and the results will be awaited with attention. One benefit, somewhat negative in character, may even now be derived from Professor Germain-Sée's researches—viz., the realization of the utter futility of the methods of inhalation so long adopted, and the uselessness of the inhalers now commonly employed. If inhalation is ever to become a valuable agent in therapeutics, it will probably be by the adoption of some plan analogous to that sketched above, and, according to our present knowledge, the most hopeful medicament with which to experiment would seem to be creasote."

SOLUBILITY OF NEW MEDICINES.

The following table of solubilities of some new medicines may be useful to some of our readers:

One Part of	Is soluble in		
	water.	alcohol.	ether.
Antifebrin	200	10	10
Antipyrin	1	1	50
Antithermin	Slightly sol.	Slightly sol.	Slightly sol.
Cocaine hydro.	5	10	—
Iodol	5,000	3	1
Paraldehyd	10	—	—
Pyridine	1	1	—
Quinoline tart.	80	150	—
Resorcin	1	1	—
Salol	—	5	5
Thallin (sul.)	7	100	—
Thallin tart.	10	—	—
Urethane	1	0.6	—

TRIGEMINAL NEURALGIA AND IODIDE OF POTASSIUM.

In the last number of the *Neurologisches Centralblatt* reference is made to some interesting facts related by Dr. S. Ehrmann as to the occurrence of severe facial neuralgia after the administration of even small doses of iodide of potassium. In the first case mentioned the patient, a strong working man of thirty-five, suffered most intense pain in the forehead and in the teeth, with sensitiveness over the whole distribution of the fifth nerve, after taking fifteen grains of the drug. A second patient after taking thirty grains had much pain in the region of the upper jaw, with pain and tenderness in separate branches of the nerve, and also œdema of the eyelids on the left side. A third and a fourth patient also suffered from similar symptoms after similar doses. There were associated in all the cases with much lacrymation and injection of the conjunctiva, but the symptoms rapidly vanished, and did not reappear on a further administration of the drug. The cases are not only interesting, but important, for it is desirable to know as much as possible regarding any peculiar effects likely to be produced by a drug which is so frequently administered as an iodide of potassium.—*Lancet.*

URETHRAN IN TETANUS.

Dr. G. Maresti (*Raccoglitore Medico*, Sept. 30, 1890) was called to see a case in which he made the diagnosis of rheumatic tetanus. The temperature was slightly above the normal; the pulse 120. Darkness, complete rest, chloral and subcutaneous injections of carbolic acid were without effect. It was finally ascertained that about fifteen days before, the patient had injured the big toe of his right foot, the skin being torn off in a spot. The diagnosis was changed to traumatic tetanus; local treatment was instituted (curetting of the lesion on the big toe, and a solution of phenic acid (30), and corrosive sublimate (3) in water (1000) was applied topically). Chloral was given three times a day, the daily amount being six grammes. The chloral was given for twenty days. Complete resolution of the opisthotonus was thus obtained, yet there remained a slight degree of trismus, with some rigidity of the pectoral and abdominal muscles. The writer then substituted urethran for chloral, its use being suggested by Prof. Coza, who remarked its manifest antagonism to the convulsions produced by strychnine, and hence recommended it in the treatment of tetanus and convulsions. The remedy was first given in the dose of two grammes a day, and finally carried up to three grammes, with total disappearance of the tetanic symptoms.

The writer claims this to be the first case of tetanus in which urethran was used.—*Jour. Nerv. Ment. Dis.*

HYPNOTIC ACTION OF ATROPINE AND DUBOISINE.

Dr. Ostermayer, of Buda Pesth, draws the following conclusions from a number of experiments made on the action of atropine and duboisine: 1. Atropine in doses of $\frac{1}{64}$ to $\frac{1}{32}$ of a grain is an undoubted sedative in maniacal cases and is indirectly a hypnotic in so far as the reduced reflex irritability which follows its administration tends to favor sleep. 2. It is not to be compared with the safe and prompt action of hyocine in this respect, although the amount of depression which follows its use in medium doses is much less likewise than that which is caused by hyocine. 3. From repeated employment the organism becomes habituated to its use and the effects become accordingly less, or even may be entirely absent. 4. Unfavorable complications, with the exception of vomiting and diarrhœa in one case, are never observed. 5. Atropine frequently has, in the author's hands, succeeded in producing a sedative effect where hyocine and morphine had proved entirely inert.

From the above it would appear that atropine in certain cases may perhaps possess some sedative properties, yet there is so much to be said on the opposite side of the question that it is doubtful whether its use will ever become general. As regards duboisine, the author concludes that, in excitable conditions and various mental affections, duboisine is comparable to hyocine, and is free

from any of the objections which may be urged against the use of the latter. 1. sedative action of duboisine may be observed within ten or fifteen minutes after the injection. 2. Duboisine's prominent action is a sedative one, and sleep ordinarily follows within twenty to thirty minutes after its administration. 3. In states of extreme excitement $\frac{1}{32}$ grain to $\frac{1}{24}$ grain are required in simple insomnia, and $\frac{1}{64}$ or $\frac{1}{40}$ grain will usually suffice. 4. Symptoms of poisoning or unfavorable effects were never noticed. 5. The action of this remedy becomes weaker under prolonged use. The remedy was used by the author in 1 per mille solution.

The author likewise claims that the system becomes habituated to the use of hyocine as is the case with atropine and duboisine. In fact, he seems to regard duboisine as quite as useful a remedy as hyocine, as regards its activity, and preferable to it on account of its greater cheapness.—*Therapeutic Gazette.*

MUSIC IN THE TREATMENT OF NERVOUS DISEASES.

Among the accessories of directly medicinal treatment, and side by side with such health-promoting agencies as rest, exercise, and change of surroundings, a definite place is due by right of its character and history to music. It is true that in later, as well as in earlier times, the sister art has been associated rather more with what is mythic and visionary in medicine than with its accredited or scientific practice. Miracle workers, mystics, and charlatans have in all ages made much of its influence on the minds of the impressible, whether truly suffering or not. There can be no doubt also that they have, as a class, been indebted in no small degree to their appreciation of this and the like natural aids for an apparent mastery of physical effects too commonly imputed to other personal and mysterious gifts of healing. In this respect they may teach us a lesson. The possession of a refined musical taste or a so-called " ear " may be denied to many persons. Some conception of harmony is probably almost universal. This understanding differs, as it must, with different minds and moods, but it exists in some degree and form, we should say, in every human being. Each temperament knows and could show, if intelligence and language were adequate, the terms of its own simplest musical coefficient, and perhaps even some of its remembered variations. The cheerful rhythm that lightened for him an hour of gloom, the flowing cadence that absorbed his petulent irritation, are as the kindred spirits of a man's family. What wonder, then, if music be found equal to the treatment of some of his diseases—those, namely, which concern his mental and nervous condition. In connection with this subject Dr. G. H. Lilley sends us a short and interesting paper on the Therapeutics of Music in Mental Diseases. He discusses with considerable force the effect of this ancient remedy on those disorders of nutrition which explain so many departures from the normal health of mind and body. A brief and lucid argument illustrates the close resemblance in physiological action between music and other stimuli which regulate the vaso-motor activity employed in tissue nutrition. Some general observations on the mode of applying the treatment suggested are likewise worth reading, and the paper as a whole forms a useful and practical, if somewhat irregular, contribution to the hygiene of the nervous system. —*Lancet.*

ADVANTAGES OF PHENACETIN OVER OTHER ANTIPYRETICS.

Dr. M. B. Herman, in the *Memphis Med. Monthly,* says, that in phenacetin we have a reliable and valuable antipyretic and analgesic, possessing advantages over antipyrin and acetanilid in that it is

1. Less toxic.
2. It seldom if ever produces cyanosis, collapse or rigor.
3. It does not produce nausea or vomiting —nor the scarlatinaform rash of antipyrin.
4. It is tasteless.
5. The administration is unaccompanied by unpleasant after effects.
6. It requires two-thirds less than antipyrin to obtain the same effect.
7. It is cheaper, being unprotected by patent.

MEDICINE.

SUBCUTANEOUS EMPHYSEMA FOLLOWING BRONCHO-PNEUMONIA.

Professor Damsch, of Göttingham, contributes a paper to the *Deutsche medicinische Wochenschrift,* No. 18, 1891, on the subject of subcutaneous emphysema, and gives details of a case in which the condition was set up in the course of broncho-pneumonia. He points out that its occurrence in association with disease of internal organs is extremely rare. It is generally produced during some act of respiratory effort, such as

straining, prolonged crying, violent vomiting, etc., but is commonly found to be limited within the alveolar or subpleural tissue of the lung itself—the so-called interlobular emphysema. This condition is not always productive of diagnostic signs, unless it spreads to the mediastinal tissues. Children are on all hands admitted to be more liable to rupture of the pulmonary alveoli than adults, but almost all writers agree that simple whooping-cough, unless accompanied by tuberculous or inflammatory disease, is hardly ever productive of subcutaneous emphysema. The latter has been produced by phthisis, especially where tuberculous ulcers are present in trachea or bronchi, and by other forms of disease tending to weaken the bronchial walls. The air, as a rule, passes from the mediastrinum to the surface along the course of the great vessels. A case is recorded in which a gradually progressive condition of subcutaneous emphysema affecting the left half of the head, face, and body, showed itself in an infant aged 15 months in the course of broncho-puenmonia of both bases. The emphysema attained a degree described as "monstrous," but the child did not appear to suffer from it, becoming quietly somnolent until its death. On examination, it was found that extensive interstitial emphysema was present over the upper lobes of both lungs, forming several rows of tiny subpleural bubbles, some of them as large as a bean. The rest of the lungs, except where consolidated by the broncho-pneumonia, were somewhat dry and anæmic. The tissues of the mediastinum were emphysematous, but the pericardium was free, and the air was found to have reached the surface by the usual route.—*Brit. Med. Jour.*

MORBID ANATOMY OF PARALYSIS AGITANS.

Dr. von Sass (*St. Petersburg, Med. Woch.*, Nos. 19 and 20) furnishes a contribution to the *morbid anatomy of paralysis agitans.* He prefaces the history of his case with a review of what has been observed post mortem by Parkinson, Scoffela, Hall, Cohn, Lebert, Skoda, Virchow, Ordenstern, Leyden, Bourillon, Rosenthal, Joffroy, Charcot, Luys and others. As is well known, these eminent observers have furnished reports of lesions most diverse in character and point of localization, many of the changes noted being either purely accidental, or else the result of those senile degenerative processes, that occur so frequently, without producing any of the characteristic tremors. The fact that this disease is essentially confined to the most advanced periods of life, when the retrograde changes of nutrition are everywhere more or less manifest, renders it difficult to isolate the characteristic lesion. Sclerotic changes, affecting now the white matter, again the grey matter of the cord, pons or basal ganglia, diffuse or circumscribed as the case may be, seem to be the most common pathological changes. The author makes no claim that he has solved the vexed question, and frankly confesses his own disappointment at the unsatisfactory result of the careful investigation. Nevertheless, considerable credit should be his due for the very full and interesting report he has furnished, both of the clinical history and the microscopical investigation of the nervous system. None but those who have followed similar studies can properly estimate the amount of time and labor involved in a histological review of the cerebro-spinal axis, peripheral nerves and muscle fibres; each case thus studied deserves to go on record.

The patient, a woman, aged seventy-one, had complained of muscular tremor for twenty years. The history and symptoms were characteristic, and the only remarkable feature was the increase of the tremor during voluntary movements; this, as Charcot has shown, sometimes occurs in the last stages. Aside from partial obliteration of the cerebro-spinal canal, abundance of the corpora amylacea at all levels of the cord, and some arterio-sclerosis, there was nothing abnormal in the cord; however, the peripheral nerves and muscles showed decided alterations. In the brachial plexus there were seen thickening of peri and endoneurium, a diffused proliferation of connective tissue with increase of nuclei, atrophy and partial appearance of nerve fibres, with coagulation of myelin, and thickening of the blood vessels. In the muscles the fibres had everywhere undergone some atrophy, so that they appeared smaller than normal, and the sheaths were crowded with nuclei—evidently a chronic myositis.

The author calls attention to the fact that, with the exception of Leyden and Skoda, no observer had made any effort to examine either the peripheral nerves or voluntary muscles; and, while not inclined to make all the symptoms dependent on these changes, he thinks they may be largely responsible for the clinical picture; and he would explain the neuralgic pains, that frequently precede the occurrence of tremors, as due to an actual neuritis.—*Cinn. Lan. and Clin.*

VARIETIES OF URTICARIA.

Dr. Beatty (*Brit. Jour. of Derm.*, May, 1891) describes a case in which a lady, aged 23, after suffering from urticaria, had a second eruption consisting of extremely irritable papules, from 2 to 6 millimetres in diameter. The papules after a few days became flattened first at the periphery, and then at the centre; brown pigmentation took place at the periphery, and the centre became pale. The papules did not develop as wheals, but were independent of them. They remained itchy for a long time, and, some of the old pigmentary spots, having for a time ceased to be irritable, became irritable again. A few elongated patches formed, with a pigmented periphery and white elongated centre. The papules continued to appear after the wheals had ceased to form. Dr. Beatty associates the case with two cases previously published by him in the *Trans. Acad. Med. in Ireland*, vol. ii, p. 37, 1884, and considers that urticaria associated with pigmentation may be divided into three groups—namely, urticaria pigmentosa; ordinary urticaria, or urticaria papulosa of children, followed by temporary brown pigmentation; and urticaria, in the course of which occur, sometimes quite independently of the wheals, extremely itchy papules, which on subsiding leave either pigmentation only, or more commonly a zone of brown pigmentation, with a white pigmentless centre. These papules continue to come out after the wheals have ceased to appear. The pigment may eventually disappear, and white pigmentless spots remain. The disease may occur after childhood.—*Brit. Med. Jour.*

NORMAL ALBUMINURIA.

Few, if any, insurance companies will accept a risk, if albumin has been demonstrated to exist in the applicant's urine, and while the examining surgeon may personally be convinced of the trifling nature of the cause which has produced the trace discovered, the company considers it inexpedient to discriminate, and hence places all such cases in the same class as undesirable.

Undoubtedly albumin can be found in many instances where nephritis does not exist and where it does not subsequently develop, and much injury and injustice is done to those who are unfortunate in one sense and fortunate in another, as the victims of temporary, cyclic, regularly or irregularly intermittent, or any other form of benign albuminuria. These individuals are the victims of a science which goes far enough to discern the signal, but is not in every instance able to make out whether it is really a signal of danger. So important is this question of the forms of albuminuria which are not of necessity dangerous to life, that everything bearing upon it should receive careful consideration.

Senator ascertained to his own satisfaction that there was a "physiological albuminuria" some nine years ago, and believed that the source of the albumin is the epithelia of the urinary passages, and of the tubules of the kidney which undergo periodical desquamation.

The difficulty of demonstrating the slight amount of albumin present in health, lies in the fact of its high state of dilution. Posner has proposed a method of detecting the presence of small quantities of albumin, which is a modification of the process advanced by him in 1886, and which consisted in the free addition of acetic acid to the urine, which converted the albumin into a non-coagulable acid-albumin. After evaporation and filtration the albumin is made apparent by the ferro-cyanide of potassium.

This he has modified as follows: Precipitate with alcohol, wash the precipitate with hot alcohol, then with cold ether, and throw upon the filter boiling concentrated hydrochloric acid. If albumin is present on the filter a beautiful violet color is obtained.

Pavy has given an excellent description of the transitory albuminuria tending to recur in a cyclical manner, and many have since added their observations on this interesting phenomenon.

It is now quite generally accepted that the condition may arise from dietetic causes as well as from muscular exercise, and some observers, among them Falkenheim, have found it in certain individuals always following rest in bed. In one case lying upon the left side produced a marked increase in the albumin, due it was thought, to compression of the renal veins by a large spleen.

Dr. Lewis, of Hartford, has found that although from six to ten per cent. of persons who apply for life insurance have more or less albumin in their urine, still the mortality rate "both of selected lives and the general public" rarely exceeds 3 per cent., from which he infers that only about 30 or 40 per cent. of albuminuria cases terminate fatally. While it is well to bear in mind the possibility of albuminuria without nephritis, we must not fall into a habit of regarding the presence of albumen as trivial and thus overlook the really serious cases.—*Med. Record.*

TRAUMATIC NEUROSAL PEMPHIGUS.

R. F., aged 17, a well-nourished bright-looking girl, had suffered from fits of an epileptic nature, brought on by a fright at school, from childhood. In December, 1887, while cutting wood, she chopped off the distal phalanges of the index and ring fingers, and cut through the middle phalanx of the middle finger. She was taken into the Cottage Hospital at Sevenoaks, which she left in a month with the wounds unhealed; they remained open for three months. Shortly afterwards patches of redness followed by blebs appeared on the left wrist, hand, and arm. The eruption was peculiar from the rapid way in which it spread; sometimes in a quarter of an hour the whole hand and arm would be covered with large blebs, which would burst and give out a thin sticky watery discharge, which on drying would leave the surface of the skin of a purple or bluish tint. The circulation also seemed very feeble.

In February, 1889, she had a crop of these on the left leg. Up to that time she was rarely without a series of blebs or threatening of them for quite twelve months. Various remedies, principally arsenic and iron, with external applications, were tried without effect. I admitted her into the Norwood Cottage Hospital, and having found the puckered cicatrices of the ring and middle fingers, especially the latter, very tender, I amputated the stump just beyond the proximal joint of the middle phalanx.

In March, 1889, she had a much slighter return of vesicles, and in August of the same year, a single vesicle, after being at the seaside, since which she has had no return. At this time a small fragment of bone worked out of the dorsal surface of the wrist.

The vesicles in this case occurred in irregular patches upon both the front and dorsum of the forearm, in the area of distribution of both the median and the ulnar nerves. That the irritation was reflex is rendered probable by this scattering of its effects and the occurrence of the disease on the leg of the same side, as well as its cessation after removal of a source of irritation upon the median nerve alone.

A microscopic preparation of the scar on the amputated portion, kindly made by Mr. H. G. Plimmer, shows hypertrophied papillæ with new small cell inflammatory growth round vessels and nerves extending in all directions.

June 8th. Since the above was sent for publication, a slight return of vesicles has occurred and may probably require an operation upon the other finger. She has been quite free for eighteen months.—Dr. John H. Galton, in the *Brit. Med. Jour.*

ON SOME POINTS IN THE PATHOGENESIS OF AURAL VERTIGO.

Dr. Oren D. Pomeroy communicates through the *New York Medical Journal* a paper which is not intended to enter into all the causes of vertigo, but only those associated with diseases of the ear, and these are drawn principally from the experiences of the writer. It is probably safe to say that vertigo depends on cerebral and spinal disturbances; on some fault with the eyes, including any or all of its muscles, or the condition of the optic nerve; on ear affections; on stomach disorders; or any other source of peripheral irritation which acts on the co-ordinating center. The twenty-four cases illustrating this subject are taken from his private note-book.

The cases may be summarized thus: Vertigo was the result of eye or ear trouble or brain tumor in 1 case; of suppuration of middle ear in 1 case; of labyrinthine disease from traumatism in 3 cases; from sunken membrane in acute middle-ear catarrh in 1 case; from labyrinthine disease or sclerosis of middle ear in 1 case; from acute suppuration, and possibly labyrinthine disease in 1 case; from Ménière's disease in 2 cases; from suppuration and polypi in 3 cases; from sunken membrane in chronic aural catarrh in 5 cases; from labyrinthine disease, secondary to middle-ear disease in 1 case; from sunstroke or labyrinthine disease in 1 case; from sclerosis in advanced middle-ear disease in 1 case; from syphilis, epilepsy, or middle-ear disease in 1 case.

It would seem by the above summary that a more exact statement might have been made as to the specific causation of the vertigo, but the writer used what acumen he was possessed of in estimating causations.

In the review of cases, only one is recorded as vertigo from advanced sclerosing processes of chronic middle-ear disease. This might be misleading, for Dr. Pomeroy is sure he has met with a considerable number of cases of vertigo in profound middle-ear deafness with no tubal obstruction. In such cases ankylosis of the ossicula, adhesive bands within the tympanum causing fixation of the stapes in the oval window, secondary contractions of the tensor and stapedius muscles, thickening and rigidity of the membrane of the round window, exhibit sufficient causes

for producing pressure upon the perilymph and consequent vertigo. Of late, operative procedures have been instituted for the relief of this condition—such as division of the tensor tympani, of the stapedius, perforation of the membrane, division of the posterior fold, etc,—but with little effect. More recently still, the membrane itself, with one or more of the ossicles, has been removed with the hope of relieving sources of pressure, or obstruction to the passage of audible tones, but with uncertain results. The general opinion of the American Otological Society at its meeting in 1890 seemed opposed to this procedure, although it was confronted by a single case of Dr. Burnett's, of Philadelphia, where removal of the drum membrane and malleus had completely relieved a patient of tinnitus and vertigo. Dr. Pomeroy conceives that such operations may be justifiable, though he should incline to reject all cases where bone conduction was weakened.

Vertigo may be observed in any form of *labyrinthine disease*, but Dr. Pomeroy believes, always in Méniere's disease.

Labyrinthine disease from traumatism very often exhibits vertiginous symptoms, as my cases show. In hyperæmia of the labyrinth from the effect of drugs, notably of quinine, there is very likely to be vertigo, although, where quinine is administered, there may be a middle-ear causation as well. In disease of the labyrinth which is secondary to middle ear disease we often observe vertigo. It is difficult to state precisely the mode in which disease of the labyrinth causes vertigo, but, in a general way, we may conclude that pressure has very much to do with it—pressure from hyperæmia or inflammatory products. Disorganization of the labyrinth would naturally disturb the function of co-ordination. The integrity of the semicircular canals would be affected by almost any form of labyrinthine disease, and we may give these canals whatever credit they may have in presiding over co-ordination. Vertigo from any form of organic labyrinthine disease is not to a great extent amenable to treatment. Absorbent remedies, like mercury and iodide of potassium, promise the best results, perhaps, of any.

In middle-ear disease the vertigo undoubtedly depends on pressure. In great hyperæmia of the tympanum, pressure on the labyrinth waters may easily be effected through the round or the oval windows. Collections in the drum cavities, the product of inflammation, may produce a similar result. Pressure on any part of the perilymph may disturb all the functions of the labyrinth.

The sunken drum membrane causes direct pressure on the vestibule, through the stapes, it being driven inward at its fixation in the oval window. The cases here reported show a direct relation between the obstructed tube and the vertigo. Treatment relieved the patient; but, on a relapse of catarrhal symptoms with obstruction of the Eustachian tubes, the vertigo returned.

Another cause of vertigo mentioned by Dr. Burnett, of Philadelphia—to wit, spasmodic contraction of the tensor and stapedius muscles, causing temporary hardness of hearing and vertigo—Dr. Pomeroy has no experience of, though he readily sees the possibility of such a phenomenon: pressure on the perilymph from indrawn membrane.

The cases also show great frequency of vertigo in aural polypi. In these instances it needs no demonstration to show that pressure is the cause of the trouble. In malignant tumors of the tympanum there is vertigo, with, perhaps, greater frequency than in ordinary polypi. Dr. Pomeroy has no record, but, to the best of his recollection, almost all of his cases of malignant disease of the tympanum have been accompained by vertigo. In these instances the tumor is likely to grow more rapidly, attain to a greater size, and consequently cause more pressure than in aural polypi. Other causes of aural vertigo may, perhaps, be mentioned here. Syringing the ear often causes giddiness, undoubtedly from violence inflicted on the labyrinthine fluids. Dr. Pomeroy once heard of a patient who fell to the floor from an attack of vertigo while administering a nasal douche, some of the fluid having entered the tympanum. Violent inflation of the drum cavity will sometimes induce a temporary vertigo.

In reviewing the work of neurologists, it is apparent enough that diseases of the internal ear figure principally as pathogenetic factors in vertigo. This Dr. Pomeroy believes to be a conspicuous error, as in his experience a much larger number of cases of middle-ear disease are concerned in the causation of vertigo than are those of the labyrinth.

Dr. Pomeroy was led to develop this subject as in the present article, from the fact that vertigo has often been regarded as evidence of brain or spinal disease, when an investigation of the auditory apparatus might have placed the difficulty elsewhere.

SURGERY.

THE OPERATION FOR INTUBATION OF THE LARYNX WITH REPORT OF TWENTY-TWO CASES.

Dr. Hal Foster in the *Kansas Medical Journal*, reaches the following conclusions as a result of a careful study:

Intubation of itself, performed with care, involves little if any danger to life. Accidents during the operation generally result from want of care.

It prevents asphyxia, and thus gives more time for the administration of remedies, and for the system ultimately to throw off the disease. It prevents laborious and rapid breathing and lessens exhaustion. It allows a free supply of air, and thus assists in the cure of the original malady. It is the supreme resource, and as the patient cannot be made worse by it, do not postpone it until there is but a forlorn hope even from it.

Persistence of the original disease, delay in the performance of the operation, and neglect afterwards are the causes of its failure. Operate early, very slowly, deliberately, carefully and without hurry. It is never too late to operate even though the child has stopped breathing, if life is not extinct, insert the tubes and perform artificial respiration. I have saved several children under just such conditions. If strangulation is the main symptom neither age, constitutional condition nor complications can furnish a contra-indication to its performance. It alleviates suffering; it mitigates all the symptoms; it obviates secondary complications; it never adds one element of danger to the original disease.

Statistics taken collectively show that nine-tenths of the cases which render the operation needful will suffocate without it. Performed early it snatches from certain death fully two-fifths of all the cases. No patient that dies after the operation would have lived if it had not been performed. When it fails to save life the relief afforded and the substitution for the most agonizing mode of death, strangulation, for one of the least, by asthenia, are sufficient to justify its performance.

OPERATION FOR OPENING THE POSTERIOR MEDIASTINUM.

In a recent communication to the *Société de Chirurgie of Paris*, Mr. Quenu described an operation he has lately devised, in association with M. Hartmann, for gaining access to the posterior mediastinum (*Revue de Chirurgie*, No. 3, 1891.) A vertical skin incision is made midway between the spinal border of the scapula and the vertebral column. After division of the exposed portions of the trapezius and rhomboid muscles, and displacement inwards of the outer border of the sacro-lumbalis, a portion of the entire thickness of each bone and about three-quarters of an inch in length is taken from the third and each of the two following ribs. An opening is thus formed nearly five inches in length, and extending from the first rib to the upper border of the sixth. Quenu states that by separating the sides of this wound one can see very clearly the whole of the posterior mediastinum and all the organs it contains. This operation, it is pointed out, is attended with more difficulty and danger on the right than on the left side, because, as was first shown by Braune, the pleura, which on the left side passes directly from behind forwards, insinuates itself on the right side between the œsophagus and the vertebral column in order to reach the aorta. Operative penetration into the posterior mediastinum might, it is thought, be indicated in disease of any organ contained in this part of the thoracic cavity, but is most likely to be needed in cases of impacted foreign body in the lower part of the œsophagus. The anatomical conditions in this operation are not favorable to removal of malignant disease of the gullet unless the growth is of very limited extent.—*Brit. Med. Jour.*

STERILITY OF PUS IN ABCESSES OF THE LIVER.

An unfortunate accident which, however, was unattended with any bad consequences, happened to a surgeon a short time ago, who was operating for the relief of a large hepatic abscess, about which there were no adhesions. The surgeon, M. Peyrot, had just withdrawn about two litres of pus from the abscess, and was proceeding to wash the cavity out when the hepatic incision disappeared from the field of operation, and it was only after much difficulty, and the expenditure of twenty minutes in manœuvring that it was again discovered. A certain quantity of pus had evidently escaped into the peritoneal cavity; nothing, however, followed this accident. No untoward symptoms occurred, and the patient made an excellent recovery. In order to explain the fact of the harmlessness of the pus, it is essential to recollect that Saveran and Neltee have shown that pus obtained from abscesses of the liver consecu-

tive to dysentery is usually sterile.—*Med. Press and Cir.*

STATISTICS OF BREAST AMPUTATIONS.

Terrillon, in a recent number of the *Bulletin General de Therapeutique*, publishes a practical paper on the immediate and remote results of a hundred cases of amputation of the breast performed by himself. They are divided into forty-eight cases of carcinoma with enlarged axillary glands; thirty-one of mixed growths, mainly sarcomatous; twenty-one of adenomata or cystic growths. Out of the first series, forty-two are dead, but recurrence has taken place in all of the remaining six. Of the second series, two only are dead; one of these lived eight years, recurrence taking place in the region of the scapula, the other lived four years, recurrence showing itself in the axillary region. Of the last series all the patients are alive. Thus, out of the whole number submitted to operation, fifty-six are still living, and forty-four were only benefited in varying degrees. With regard to the forty-four carcinomatous cases the following details may be given of the periods of their survival:—One patient lived seven years; two survived five years; four four years; five three years; eleven two years; twelve one year and a half; and lastly, eight less than one year. He remarks that recurrence seems to be the rule when, after removing the breast, it is found at the same time necessary to extirpate some of the axillary glands. The recurrence, moreover, most commonly takes place in the first years, that is, there is seldom survival beyond the seventh or eighth year. The paper includes various remarks about complications arising from the operation and the after treatment.—*Med. Press.*

PERMANENT ANTISEPTIC IRRIGATION.

Dr. E. von Meyer recommends this method of treating septic wounds, which he has successfully practised in Czerny's clinic during the last two years. It consists in placing the affected part in the metal tub, and keeping up constant irrigation by means of an irrigator provided with a spiral coil of perforated metallic tubing which acts as a "sprinkler." The limb is lightly covered with gauze, and suspended in the tub by broad bandages attached to hooks at the sides. The bottom of the tub is sloping so that the fluid can flow off readily through an opening connecting with a tube, which terminates in a vessel placed under the bed. The cases in which this method has been employed comprise:

1. Cases of general sepsis arising from subfascial phlegmons and septic conditions after fractures.

(*a*) Cases of progressive gangrenous phlegmons, of spontaneous origin or developed after compound fractures.

(*b*) Septic amputation stumps after intermediate amputations and resections.

2. Extensive lacerated and contused wounds, with marked gangrene and sepsis of the soft parts.

On the ground of the results obtained in these cases, the author presents the following indications for the employment of permanent antiseptic irrigation:

1. In all cases of fractures and luxations attended with suppuration, especially when the surrounding parts are phlegmonous, and distinct signs of commencing sepsis are present.

2. In all cases of deeply seated progressive phlegmons in which gangrene is likely to occur.

3. In all cases mentioned above in which resection or amputation has to be performed, owing to pronounced general septic infection, or for the treatment of septic amputation stumps.

4. In severe contused wounds in which a conservative method of treatment is selected, as soon as the integrity of the soft parts is threatened by gangrene, and the danger of a general septic intoxication is present.

For irrigation a number of antiseptic fluids have been proposed, but the best, in the author's opinion, is a 1 per cent. solution of aluminium acetate. In cases of septic and phlegmonous wounds the author also makes a liberal use of iodoform, to which he assigns an important part in the disinfection of septic wounds. The gauze layer should be changed twice every day, the wound carefully inspected, and all gangrenous fragments of tissue removed, so that the antiseptic solution comes in contact with a clean surface, washes away all pus, and penetrates the tissues. The drainage tubes in the wound must be carefully watched, for they become easily plugged with fragments of necrotic tissue. Unless all these details are attended to, no success can be expected from permanent irrigation; for the fluid then flows over firmly adherent necrotic portions, beneath which abundant pus stagnates. Permanent irrigation should only be discontinued when all signs of sepsis have completely disappeared, and the wound appears perfectly cleansed.—*Deut. Zeit. für Chir.*

NEPHROLITHOTOMY IN A BOY, AGE 10.

Mr. Bilton Pollard reported a case of a boy who during the past three years had been subject to attacks of abdominal pain associated with hæmaturia. The attacks of pain were not characteristic of renal calculus. The hæmaturia was sometimes profuse. The urine contained no pus, and when free from blood it appeared to be healthy. The right kidney could be felt, it was not tender on pressure and there was no renal tumor. The boy's general condition was good, although he was anæmic. On December 25th, the right kidney was explored through the lumbar incision at the North Eastern Hospital for Children. The stone could be felt in the pelvis of the kidney by the finger, and was also struck by the exploring needle. It was easily extracted through the cortex of the kidney. The stone weighed twenty-seven grains. The kidney bled rather freely, but the bleeding was stopped easily by plugging the wound in the kidney with gauze. The gauze was removed on the following day, and the tube on the second day after operation. No blood appeared in the urine after the operation, and as the discharge of urine from the wound did not diminish materially, the renal pelvis was again explored on the fourteenth day after the operation, as it was thought possible that it might be plugged with blood clot. No clot was found. A fine tube was passed in the direction of the ureter and some lotion syringed through it with the object of dislodging a clot if there was one impacted in the ureter. The quantity of urine which escaped from the wound now diminished quickly and ceased entirely after the fifth day, and the patient made a complete recovery. It was now sixteen weeks after the operation and the patient continued well. From inquiries which Mr. Pollard had made he thought nephrolithotomy was a rare operation in childhood. Mr. R. W. Parker had twice operated for renal calculus in children at the East London Hospital, but no cases of the kind had occurred in three other London children's hospitals, nor yet at the Pendlebury Children's Hospital. Mr. Pollard reported the case with the view of ascertaining the experience of others in regard to renal calculus in childhood.—*Med. Press.*

ABDOMINAL SECTION FOR ACUTE INTESTINAL OBSTRUCTION.

Jordan Lloyd (*London Lancet*) after giving the details of eight cases reaches the following conclusions:

1. In acute intestinal obstruction our attention should be primarily directed to the strangulation of the walls of the bowel rather than to the fæcal current. When strangulation exists immediate operation is demanded.

2. The ordinary text-book distinctions between obstruction in the large and small bowels are not always to be depended upon.

3. In all obstructions above the rectum calling for operation, median abdominal incision is the proper primary procedure.

4. When the abdomen is open the examination of its contents should be systematic and expeditious, the hand being introduced into the peritoneal cavity, if necessary, and if the obstruction is not quickly discovered, the most distended coil should be fixed to the skin and opened at once. If the large intestine is the part involved, the cæcum or sigmoid should be brought through a special opening made in either groin.

5. With proper precaution a few feet of bowel may be withdrawn from the peritoneal cavity, and returned without difficulty and without serious risk.

6. Rapidity of procedure with a minimum of disturbance are the essentials of operative procedure.

7. The number of lives saved by abdominal section will increase, as earlier and more accurate diagnosis comes to be made.

OPERATION FOR NASO-PHARYNGEAL POLYPI.

Baracz (*Centralbl. f. Chir.*, April 18, 1891) describes a method for which he claims the following advantages, namely, that it avoids much bleeding and enables the operator to get the growth completely away. The plan has, as he states, been employed previously by others, but has not met with the general acceptance which it deserves. It is principally applicable to those growths which cannot be removed by the forceps through the nostrils. Chloroform is not administered, but the part affected, together with the surface of the lips and nose, which has to be incised, is rendered insensible by means of cocaine. An incision is made through the lip just to one side of the middle line, and the incision is carried up through the fleshy part of the nose on one side of the septum as far as the nasal bones. Should the growth be very large the nasal bone may be cut and turned aside, along with the flap of skin, to the corresponding side of the face. This flap is grasped by an assistant, and the nasal aperture enlarged slightly by bone forceps if

necessary, though it is very rarely needful to do so. One finger can then be introduced into the nostril and another behind the soft palate, and the polypi enucleated with the finger nail. In children an anæsthetic must be employed. Baracz states that the whole nasal cavity, so far as the base of the skull, can thus be got at. If the cavity is well irrigated out afterwards the bleeding is not great. The edges of the wound are then accurately adjusted, and only a linear scar remains. Baracz claims that by this comparatively simple incison quite as much can be effected as by the larger-planned operations of Langenbeck and others.—*Brit. Med. Jour.*

OPERATIONS FOR PROMINENT EARS.

Monks (*Boston Med. and Surg. Jour.*, Jan. 22, 1891) discusses the treatment of this deformity. In his first case an attempt was made to reduce the prominence of the ears by keeping them pressed close to the side of the head by means of a spring passing over the top. This contrivance was faithfully tried for several months, but no great improvement could be seen. In the second case a vertical strip of skin and cartilage was taken from behind. The anterior surface was left intact. This operation was successful, although the cartilage took a long while to heal, and a vertical fold of skin was formed on the front aspect of the ear where the cartilage had been brought together. In three other cases an elliptical piece of skin was removed. The result was satisfactory. A girl of 5 years was similarly treated, and the result was satisfactory.

Operations by excision of skin and cartilage are only called for when the cartilage is stiff. It seems almost impossible to perform an operation on the cartilage which will leave no trace of undue prominence, scar or depression. The method by excision of the skin alone is applicable to cases where the cartilage is not stiff. The shape of the ellipse varies somewhat with the case, the strip being widest where the prominence is most marked. In all cases the inner incision should be close to the bottom of the culcus. As the cartilage tends to regain its old position after the operation, a broad piece of the skin should be resected; that is, a piece equal to more than half the breadth of the back of the ear. The sutures may be removed from the third to the sixth day. A bandage is to be worn for ten days or two weeks, and for several months a night cap should be used.—*Univ. Med. Mag.*

GYNÆCOLOGY.

GYNÆCOLOGY IN THE JOHNS HOPKINS HOSPITAL, BALTIMORE.

During a recent trip to Baltimore, Dr. J. E. Graham and I enjoyed the hospitality of our old friend, Professor Wm. Osler, and were also entertained by others of the leading medical men of Baltimore, whose cordial manner cannot help but foster warm and friendly feelings. Johns Hopkins Hospital is unique and must be seen to be appreciated. Though it is situated near a densely populated part of the city, where clinical material is abundant, it is so elevated that it commands a view of the city and suburbs. The Hospital buildings are so constructed that they give the most perfect sanitary results. The grounds are spacious and well kept. Everything seems so ordered that both the convenience of the medical men and the best interests of the patients may be served. Post-graduate work is only done. The teaching is thorough, and such a scientific atmosphere pervades the place that it cannot help leaving a favorable mark upon all who are fortunate enough to be able to avail themselves of its manifold advantages.

In the Hospital my time was chiefly occupied with work in the gynæcological department, under Professor Howard A. Kelly and Dr. H. Robb.

One is particularly impressed with the great amount and thoroughness of the work. From the out-patient clinic suitable cases are chosen, and the wards are filled with many patients demanding operative measures for their relief.

The wards are well lighted, suitably ventilated, scrupulously clean, and supplied with every convenience. The appearance of the operating room is unique, with its tiled floor, clean walls, brass table with glass top, instrument cases with glass shelves, wash basins, trays, vessels of glass of different color for different solutions, sterilizers, and glass bottles for cotton, bandages, etc., and in fact every appliance for convenience and perfect cleanliness.

Professor Kelly believes that the greatest difficulty is encountered in freeing the hands from infectious germs—the most harmful of which he takes to be the streptococcus aureus. In order to be sure of avoiding the baneful effects of these germs, he goes through and causes his assistants to adopt a most rigorous course. First, they dress in white duck for the operation. The hands and arms are bared, and after scrubbing for ten minutes

with soap and hot water, they are rinsed with pure water and soaked in a saturated solution of pot. permanganate, which is again rinsed off in distilled water, and then the brown color is removed by a saturated solution of oxalic acid, which in its turn is rinsed off in tepid distilled water. The instruments are wrapped in a towel, sterilized by steam, and placed in a glass tray under distilled water ready for use.

I saw some "hand cultures." After an assistant had washed his hands and soaked them in perchloride of mercury solution, some scrapings from under the nails were placed in culture media. In due time germs were produced, some of which, when injected into a rabbit, caused death. Dr. Kelly believes that perchloride of mercury solutions retard but do not absolutely prevent the production of poisonous germs, whilst saturated solution of permanganate of potash absolutely destroys the germs. The patients are prepared with as great care as the instruments and the hands of the operator. Ether seems to be used oftener than chloroform. I saw a good many cases of vaginal hysterectomy, all doing well. One was notable, as the operation was done for prolapse of the uterus, which was of such a marked character that no other plan of treatment seemed to offer a chance of relief from her distressing symptoms. Some of the hysterectomies were done for myomata, and Dr. Kelly believes that where the life of the patient is rendered unbearable by pain or disease caused by pressure from myomata, and when other treatment is unavailing, hysterectomy is justifiable. One case of cystic ovary was operated upon by Dr. Kelly in which the adhesions were so dense and general and the bleeding was so free that the cyst could not be removed without seriously threatening the life of the patient. He broke quickly through the adhesions of the pedicle ligated it, emptied the clots out of the sack and washed it out with warm water, drained and packed with iodoform gauze, with good result. In a case of subperitoneal myoma removed by Dr. Robb the omentum was attached, and its vessels so enlarged that, instead of separating adhesions, he tied off omentum, tied the pedicle and removed the tumor, after which he tied the pedicle again by cross stitches.

There were very many other operations of great interst to me. In dilating the cervix-uteri, Professor Kelly uses the dilators with repeated quick movements, changing the position so as to dilate evenly. In repairing lacerations of cervix, he cuts the scar tissue away very freely, and uses silk-worm gut with catgut for the superficial stitches. In lacerations of the perineum he does a very neat operation, using Emmet's curved scissors, and denuding higher up on the vulva than many advise. Catgut for the lesser and silk-worm gut for the deeper stitches are used. Glass catheters are preferred, as they are so easily cleaned.—*Albert A. McDonald in the Canadian Practitioner.*

RECTAL FISTULA AFTER PYOSALPINX.

Dr. Ozenne (*Revue Obstêt. et Gynécolog.*, March, 1891) recently had under treatment a patient, aged 30, suffering from chronic pelvic disease. Eight years previously salpingitis followed a forceps labor. The pus escaped into the rectum, and after three months' rest no more purulent material came away from the bowel. Six years later severe pelvic pains again set in, with symptoms of metritis and pyosalpinx. After many months of ill health the pus once more escaped into the rectum, this occurrence being followed by great temporary relief. At length the patient fell ill again. On examination a swelling could be felt in the left iliac fossa. The orifice of the fistulous tract was detected about 3½ inches above the anus. Dr. Ozenne believed that, seeing how long the pelvic disease had existed, abdominal section would entail great difficulties and dangers. He treated the patient by rest in bed and by vaginal injections of a 1 in 4,000 sublimate solution night and morning, whilst at the same time the rectum was washed out with about five quarts of a warm boracic solution, thrown up slowly so that it might be retained for some time. Every morning a boracic solution was thrown into the abscess, a double-channelled gutta-percha sound being passed into the fistula. Laxatives and tonics were given. At the end of a fortnight the patient was able to get up and lie on a sofa; the injections into the abscess were left off. For a month longer the enemata and vaginal injections were continued. The general health was completely restored, and the walls of the pelvic abscess had contracted. Eight months later the patient was still in good health, without any sign of recurrence of her pelvic troubles.—*Brit. Med. Jour.*

OBSTETRICS.

UTERINE IRRIGATION OR INTRA-UTERINE CAUTERIZATION.

Dr. Eichholz, in the *Frauenarzt*, gives statistics to prove that during epidemics of

puerperal fever the mortality was higher in cases in which intra-uterine injections were made than when they were omitted. In Gusserow's clinic, *e. g.*, the mortality was 3.8 per cent., the injections being used, and after they were omitted the mortality was reduced to 0.39 per cent. Breisky and Fehling made similar observations in 1877. E. claims that the injections are at times not only useless, but may be dangerous, for it is possible to bring infection into the uterus by introducing foreign material from the vagina. The injections have in many cases produced symptoms of poisoning. Steffek reports a case which ended fatally after the use of a corrosive-sublimate injection (1:5,000), in a woman who was delivered of a macerated fœtus in the fifth month, the symptoms of poisoning appearing one hour after the injection; the patient died on the seventh day. Maurer observed a case of poisoning due to an injection of carbolic acid. The author gives another reason to prove that the injections are dangerous, namely, the fact that the fluid enters directly into the venous system, and also that it may be carried into the system through the Fallopian tubes, as evinced by pains in the abdomen, general peritonitis, and death. Chrobak collected eighteen cases of death due to the use of intra-uterine injections of caustic fluids. He furthermore claims that we have to consider the amount of pressure used in injecting, as also the quantity. If the pressure is at all great, considerable irritation is produced; consequently there must be no pressure and the quantity must not be too great. He therefore concludes that it is better to make direct applications, and recommends the use of chloride of zinc (fifty per cent.) as practised by Rheinstädter: His method of employing the zinc is as follows: He introduces a Trelat's speculum into the vagina, carefully cleansing the external genitals and the vagina by means of cotton soaked in corrosive sublimate (1:1,000). The cervix is then drawn down and the canal dilated. Next he curettes the uterus, and then makes a uterine application by means of a brush—the thickest portion of which does not exceed five millimetres—dipped in chloride of zinc (fifty per cent.). The vagina is then cleansed again, and a cotton pad placed over the vulva and changed when soiled. The brushes are never to be used more than once. Author reports twelve cases of premature births treated in this manner with most excellent results.

He summarizes the subject as follows:

1. That uterine irrigation, used as a prophylactic measure or for therapeutic purposes, is not as valuable as is generally believed.

5. When we consider its inefficacy on the one hand, and its dangers on the other due to entrance of air and water into the vessels and tubes and the danger of poisoning, we must consider it preferable to adopt other methods.

3. This method can in the majority of cases be replaced by the application of $ZnCl_2$, as described by Rheinstädter. It is not as dangerous as is irrigation, and undoubtedly disinfects the interior of the uterus much more thoroughly.—*Exchange.*

THE PLACENTA IN ECTOPIC GESTATION.

The question of the growth of the placenta after the death of the fœtus in cases of ectopic gestation is not only interesting in itself, but may be important from a medico-legal point of view. It has long been suspected that the growth of the placenta must outlive the fœtus, for instances are common in which a large placental mass exists without the trace of an ovum, or at most with a fœtus obviously much younger in point of age. Recent observations by Mr. Tait and by Dr. Bantock have now placed this developmental survival of the placenta in occasional cases of this kind beyond a doubt. There remains, however, the interesting histological question as to how the placenta continues to grow. As has been pointed out by Dr. Barnes, the placenta is a double organ, consisting of a fœtal and of a maternal portion. *A priori* considerations would suggest that the growth must bear principally if not exclusively on the maternal portion, but microscopical information, which alone can settle the point, is wanting, though doubtless now that attention has been called to the lapsus, the requisite investigation will shortly be carried out. This fact, moreover, has a bearing on the treatment, for it would obviously be useless to kill a fœtus by electricity or other means leaving it *in situ* if the placenta is likely to continue growing, for rupture of the tube and hæmorrhage will as certainly follow as if the fœtus were present in person.—*Med. Press.*

TREATMENT OF SEVERE VOMITING OF PREGNANCY.

Dr. Amand Routh, after alluding to the difference between the vomiting *of* pregnancy

and the vomiting *in* pregnancy, noted the anxiety occasioned by severe forms of this condition, and the advantage of having an easy and efficacious mode of treatment in itself free from risk. Although it was now generally held to be reflex, and due to some local irritation at or near the os uteri internum, great difference of opinion existed as to the exact pathology and to how it was produced. The author did not think the vomiting was often secondary to displacement or incarceration, and showed that it occurred where no malposition existed, and that, even when vomiting occurred with misplacement, replacement did not cure it. The treatment by drugs, accessory measures, replacement, Copeman's dilatation, local applications of cocaine, counter-irritation, etc., was reviewed, and it was shown by several cases that painting the cervix and the end of its canal with iodine paint (equal parts of iodine, iodide of potassium, spirits of wine, and water) had, in the author's hands, never once failed in the last seven years, at once to stop the sickness, which might, however, begin to return from the fifth to the fifteenth day, when it was almost certainly permanently arrested by a second application. A prompt use of this remedy in cases threatening to become urgent would prevent the occurrence of the so-called "uncontrollable" or pernicious vomiting, which differed only in degree, and not in kind, from the milder forms. Induction of abortion would still be required when the vomiting was due to the presence *in utero* of a foreign body, such as a dead fœtus or a hydatid or fleshy mole, but might otherwise, by this proposed remedy, be avoided.

PÆDIATRICS.

A RECORD OF THE RESULTS OF FIVE HUNDRED AND TWELVE CASES OF INTUBATION OF THE LARYNX.

Bleyer has embodied in an interesting paper, which appears in the *Archives of Pædiatrics* for March, 1891, his observations made in an experience covering the above number of cases of intubation. In order to show that the operation has now attained a position which entitles it to recognition as a feasible and practical surgical procedure, he compares its results with those of tracheotomy. Of the 512 cases in which he performed intubation, thirty-seven per cent. recovered, while the most complete statistics of tracheotomy, those of Lovett, show the proportion of recoveries from that operation to be twenty-eight per cent. With regard to the details of the operation of intubation, Bleyer insists upon the necessity of a preliminary laryngoscopic examination, the performance of which will be facilitated, when the patient offers resistance, by the employment of a gag and tongue-tractor of his own device. The examination is of value, not only because it will reveal the nature of the affection for which the intubation is contemplated, but because, in cases of diphtheria or of croup, it will permit the operator to see and remove any loose membrane which might be pushed downward by the tube—a complication which the writer regards as the rule rather than the exception.

The matter of the selection of the size of the tube to be employed in a given case is one which requires some experience. It must be remembered that the size of the larynx varies considerably in different children of the same age.

Daily removal of the tube for the purpose of cleansing it from accumulated loose membranes and secretion was practised in many of the writer's later cases. He prefers that it should be accomplished by means of the two forefingers rather than the forceps. In a large number of the cases he found that the tube could be dispensed with after the second, third or fourth day. In a few cases its re-introduction was necessary.

By way of local treatment, irrigation of the nostrils with a solution of peroxide of hydrogen, one part to two of water, is recommended, a soft rubber catheter being used for the purpose. After the nares have thus been thoroughly cleansed, the pharynx and larynx are to be irrigated with a 1–8 solution of the peroxide of hydrogen, the patient's head being held forward over a basin in order to facilitate the escape of the fluid. These cleansing applications should be made every two hours. At the times of removal of the tube irrigation with a solution of bicarbonate of sodium, half an ounce to fourteen ounces of luke-warm water, is advised.

As to medicinal treatment, Bleyer speaks favorably of his experience with calomel, given in half-grain doses every hour. In the administration of food the stomach tube was, for the most part, employed. A source of danger, which is to be kept in sight in these cases, is an inordinate desire for fluids, the result, not of actual thirst, but of uncomfortable sensations caused by the presence of the tube. In five cases, through the

too frequent administration of liquids in response to the patient's appeals, death took place in consequence of mechanical obstruction of the heart from distension of the stomach.

As sequelæ of intubation, ulceration from pressure of the tube and alterations in speech are mentioned, the former having been met with in almost one per cent. of the cases; the latter may vary from partial to complete aphonia, but is always amenable to treatment. From a tabular statement of the results of the 512 cases it appears that of the patients under 3 years of age, 74 recovered and 197 died; while of those over 3 years old, 115 recovered and 125 died. The chief causes were extension of the membrane to the bronchi, bronchitis, pneumonia, sepsis and exhaustion.

In conclusion, the writer points out the advantage of intubation by means of a rubber catheter and the intubation tube over tracheotomy, in connection with operations upon the mouth or throat, when much hæmorrhage is anticipated—*Univ. Med. Mag.*

THE TREATMENT OF INFANTILE PARALYSIS.

The following is an outline of treatment of infantile paralysis recommended by Simon. At first counter-irritation over the spinal column at a point corresponding to the origin of the roots of the nerves affected. For this purpose the least painful agents should be chosen. The functions of the skin should be stimulated at the same time by means of baths of hot water or vapor, given in the bed. Chloral, aconite and canium may be employed to calm nervous excitement. After the first eight days, electricity should form the basis of the treatment. Simon uses a weak galvanic current, applying the positive pole to the shoulder and arm, the negative pole being placed in a basin of water in which the child's hand rests. The sitting should never last more than eight or ten minutes. At a later stage faradism may be used, always, with the greatest caution. Among drugs, nux vomica is of the greatest service. A drop of the tincture is given twice daily at the two principal meals. At the end of ten days, or earlier if indicated, the nux vomica should be replaced by arseniate of sodium, a sixty-fifth of a grain at a dose. The use of these two remedies alternately is to be continued throughout the case. Salt and sulphur baths are recommended, but only in the last stages of the disease. Above all, Simon enjoins us never to be discouraged, as the treatment must necessarily be very long.—*La France Méd.*

OCCLUSION OF DUODENUM IN A NEWBORN CHILD.

MM. Porak and Bernheim (*Bull. et Mém. de la Soc. Obstét. et Gynéc. de Paris*, No. 4, April, 1891) describe a case where a woman was delivered at the eighth month of a sickly female child. There was hydramnious, and over six pints of fluid came away during labor. There were two small fibrous deposits in the placenta. On the first day the child vomited dark matter, each attack of vomiting coming on about three-quarters of an hour after suckling. On the third day, as no meconium had passed, imperforate rectum was suspected; but a sound could be passed for over two inches up the anus. An enema was given, and a little meconium came away; but the vomiting continued, and the infant died on the fifth day. The stomach was found much dilated; the lower part of the large intestine was full of meconium, but the remainder of the intestinal canal was like a little packet of worms. The stomach communicated by a contracted orifice, apparently the pylorus, with a blind pouch which had no connection of any kind with the rest of the intestine, which terminated above in a blind extremity close to the pancreas, which opened into it. In a similar case reported by Crooks in 1828, the pancreatic duct opened into the pouch connected with the stomach. Luton described in 1855 a third case where that pouch communicated with the blind end of the intestine by a ligament. There was a similar breach of continuity between the large and small intestine. No trace of peritonitic bands could be seen in Drs. Porak and Bernheim's case.—*Brit. Med. Jour.*

HYGIENE.

THE TETANUS BACILLUS.

Guido Tizzoni and Giuseppina Cattani have recently published some new facts concerning the bacillus of tetanus, which may possibly reconcile some discrepancies between their observations and those of Kitasato. They find (*Riforma Medica*, 1891, p. 157) that virulent cultures always liquify gelatine, have a decidedly alkaline reaction, give out

a disgusting odor, and cause death by acute tetanus in animals in twenty-four to thirty-six hours. Less virulent bacilli still liquefy gelatine, but the reaction soon becomes acid. Still more attenuated cultures show growth much sooner, give off far more gas, do not liquefy the gelatine, give out no bad smell, and have a marked acid reaction. Thus to various grades of virulence correspond notable alterations of the morphological and cultural relations, also of the products, and we here again observe the strict tie which exists between peptic enzyme and the toxine of tetanus bacilli. As to cultures in serum, observers differ. Kitasato has not seen the liquefaction of coagulated blood serum, which has now been noticed by several observers besides the above. Again, as regards liquid serum, its successive solidification and liquefaction by the tetanus bacillus, as first noticed by the authors, has been confirmed by Nikiforoff (*Zeitschr. f. Hygiene*, Bd. 8, p. 497.) The differences are possibly explained by assuming that Kitasato worked with a less virulent bacillus. The authors have already shown that cultures on meat broth and agar are weakened even in the second generation ; the same weakening follows culture in other media, only after a long interval of some months. Cultures kept for more than a year under various gases (H. N. Co_2) gave attenuated cultures when transplanted into gelatine, but similar cultures *in vacuo* yielded very virulent cultures. Perhaps this was due to freer development of gas by the cultures *in vacuo*. The acids of attenuated cultures are fatty acids, chiefly butyric, as already shown by Kitasato and Weyl, but the addition of butyric acid made no difference to the culture; the acidity is thus a consequence rather than a cause and the fact that it is due to fatty acids, and its small amount, explain why it does not annul toxicity as mineral acids do. Virulent gelatine cultures continued to be very toxic for six months when filtered and kept in the dark, but after that time they lost their virulence altogether, or only caused emaciation and death in about three weeks. They were strongly acid and odorless. In contrast to this, the toxalbumen of tetanus, kept dry for a much longer period, preserved all its toxicity.—*Brit. Med. Jour.*

PRACTICAL INSTRUCTIONS FOR PUBLIC HEALTH DIPLOMAS.

Sixteen different examining bodies in the United Kingdom have formulated regulations for examinations in Public Health. Naturally enough, there is considerable variation in the standards and range of subjects required, and still more in the manner in which they are specified. The recent resolutions of the General Medical Council—making laboratory training and practical sanitary work imperative upon candidates—have led to further modifications in the synopses issued by the examining boards, and, as the Education Committee of the Council pointed out in the report discussed at the meeting on Saturday last, "there is difficulty in understanding what the whole of the regulations under which some of the authorities grant the diploma in Public Health really are." The difficulty is one with which the teaching bodies and intending candidates for these diplomas are only too well acquainted, although perhaps inevitable in a period of transition like the present. The clear and well-timed report of the Education Committee will enable the respective examining boards, with or without pressure from the General Medical Council, to bring their regulations into more explicit form, and to ensure the high standard of efficiency which the Council prescribes.

The laboratory work required should comprise the study of air, water, food, clothing, soil, sewage ; meteorology, bacteriology, disinfection, parasites, and certain branches of human and comparative pathology. The Committee suggested that use might be made of the resources of the veterinary school, and that candidates should be required to produce evidence of having received practical instruction in diseases of animals in relation to public health. The Council adapted the recommendation of the Committee in a slightly modified form (see page 1230).

The course of laboratory instruction must cover a period of six months after the candidate has obtained a registrable qualification, in a laboratory or laboratories approved by the examining body. Several efficient laboratories are now being organized, and it is important that the other authorities should clearly define in detail, as the Conjoint Examining Board in London have already done, the points upon which practical instruction is required.

The Committee offer no suggestions with reference to the six months' course of practical out-door sanitary work with the medical officer of health for a county or large urban district, which is to be required in the new order of things. Facilities for this purpose have already been given in Newcastle and elsewhere, but it would be interesing to know how far the new system of pupilage has been

acccepted by medical officers of health generally, and by their sanitary authorities.

Both courses of practical work must be taken in a post-graduate year, and at least twelve months must elapse after obtaining the first registrable qualification before a candidate is admitted to the examination for a diploma in public health, the object being "to secure the attention of candidates to the higher special studies, undistracted by the ordinary work of the medical curriculum."

The Medical Council has taken strong action to ensure that the next generation of medical officers of health shall be scientific men, well trained in the theory and practice of this special branch of medicine. Let us hope that the sanitary authorities of the future will also advance with the age, and that a true national public health service, worthy of the country, may at last be formed, with a Minister of Health at its head.—*Brit. Med. Jour.*

MEDICAL CHEMISTRY.

DEODORIZING NAPHTHALIN.

To deodorize naphthalin, simple mixture with benzoic acid or tincture of benzoin does not suffice. Its admixture with camphor and other deodorants has been found to be of but temporary effect. But if it be mixed with benzoin and then sublimed, it loses its tarry odor and acquires a pleasant smell, which it retains.—*Drug. Bulletin.*

NOTE ON *P*-PHENETIDIN AND PHENACETIN.

An interesting communication on *p*-phenetidin and a new test for purity of phenacetin appeared in a recent issue of the *Pharmaceutisch Zeitung*, having Ludwig Reuter for its author, of which the following is a short resume:

Physiological experiments made on rabbits and guinea-pigs revealed the fact that *p*-phenetidin is a poison, continued small doses including nephritis accompanied by albuminuria, larger doses (10 drops hypodermically(causing instantaneous collapse. One drop a day given internally sufficed to superinduce severe nephritic troubles within a few days.

When *p*-phenetidin is dropped into fused chloral hydrate, a strong color reaction ensues instantly, which increases in intensity on the further addition of the former, and on shaking, a strong reaction is seen to take place between the two chemicals. Pouring this mixture into a large volume of cold water, the latter assumes an intense purplish-blue color, while at the same time a dark pasty mass is separated. This body is almost insoluble in water, but more so in the presence of chloral hydrate. A little, however, remains to color the liquid, since 1 drop *p*-phenetidin treated with chloral hydrate is enough to distinctly tinge 2 liters of water, and the chromogen produced from 1 gram of *p*-phenetidin gives a distinct color to 40,000 parts. The new dye may be extracted from its chloral-free aqueous solution with chloroform or ether. Allowing this latter solution to evaporate, spontaneously, well defined hard crystals are formed, dark red and transparent.

Phenacetin (=acet-p-phenetidin) is produced by boiling together *p*-phenetidin and glacial acetic acid, and it will happen that acetylization is not always perfect, so that traces of *p*-phenetidin will pass over. The last traces of this impurity are exceedingly difficult to remove. In view of this fact, and in further consideration of the physiological action of *p*-phenetidin, as reported above, the presumption is warranted that this latter impurity may have been the cause of the many untoward effects following the administration of phenacetin, especially coma and cyanosis.

It therefore becomes the duty of pharmacists to look well to the quality of their phenacetin dispensed, and for this purpose chloral hydrate becomes an excelleut agent, Reuter stating that the smallest traces may be detected. He describes the reaction as follows: Liquify 2.5 grains of choral hydrate, by means of a water bath, in a small test tube, then add 0.5 gram of phenacetin and assist solution by shaking. If the mixture was not exposed to the water bath heat longer than two-third minutes,, the solution will be clear and *colorless* in the total absence of *p*-phenetidin from the phenacetin. If, however, only traces of the impurity are present, the solution *immediately* turns more or less deeply, purplish-red or bluish-purple, according to the degree of impurity.

However, it must be noted that absolutely pure phenacetin, remaining unchanged by heating during five minutes with chloral, will yield a pink coloration when the heat is prolonged to 15–30 minutes. This latter reaction, it will be seen, therefore constitutes a good test of identity for phenacetin.

The same author also mentions an iodine re-action, without, however, crediting the same with any importance. The same test

for for *p*-phenetidin, it seems, has also been employed for some time, but with better success, by Felix Goldmann, who, in a later issue of the Pharmaceutische Zeitung, makes public the details of his method. Goldmann proceeds as follows:

Dissolve with the aid of heat, 0.5 gram phenacetin in 2 ccm. of alcohol, and add 5 ccm., of a solution containing 1.0 gram of iodized potassium iodide solution (potassium iodide, 7.0; iodine, 5.0; water, 100.0) in 20 liters of water. Re-dissolve the phenacetin, which crystallizes out, by continued boiling. If pure no color re-action appears; in the presence of traces of *p*-phenetidin, however, a rose pink color develops.

Goldmann also substantiates the observations of Reuter with regard to the physiological effects of *p*-phenetidin. Administered to dogs, in the proportion or 0.1 gram per kilo of their weight, it produced marked lassitude, vomiting, acceleration of pulse, and cyanotic discoloration of mucus membranes. In addition, the kidneys were found to be irritated, the urine became strongly albuminous,and contained large amounts of *p*-phenetidin and *p*-amidophenol. However, the last two decomposition products are also present in small quantities in urine after the ingestion of phenacetin, free from *p*-phenetidin.—*West. Druggist.*

TEST FOR MERCURIC CHLORIDE.

Mr. Borntraeger recently discusses the best methods of detecting traces of mercuric chloride (in *Pharm. Centralhalle.*)

He points out that any aqueous, oily, or soap liquid containing mercuric chloride gives immediately with zinc chloride and hydrochloric acid a black-gray color, while with sulphuretted hydrogen or ammonium sulphide it immediately becomes blackened.

When shaken with a mixture of potassium iodide, acetic acid, and ether, and allowed to stand, three layers are formed, the middle one constituting a green zone of the mercurous salt.

The separation is said to be so sharp that when carried out in a narrow test tube it gives approximately quantitative results. —*Pharm Jour.*

TOXICITY OF CRYSTALLIZED ACONITINE.

The great toxicity of crystallized aconitine has recently been again illustrated in Belgium. A lady, according to the *Journal de Pharmacie d'Antwerp,* was ordered to take some pills containing $\frac{1}{4}$ of a milligram ($\frac{1}{1000}$ grain) of this alkaloid, to be repeated five times a day, but after the third dose she was seized with great nausea. A male relative scouted the idea that the pills were to blame and swallowed two of them at once, representing $\frac{1}{125}$ part of one grain of crystallized aconitine. He died amid convulsions within one hour. In commenting on this case M. Ferraud, in the *Bulletin Commercial,* calls attention to the fact that three years ago it was demonstrated to the Paris Pharmaceutical Society that $\frac{1}{4}$ of a milligram given to a grown person had nearly proven fatal. The foregoing only adds strength to the conviction that all of the so-called aconitines should be left severely alone for internal medication.—*Western Druggist.*

SALICYL-SULHPONIC ACID A NEW ALBUMIN TEST.

Salicyl-Sulphonic acid ($C_6H_3.OH.SOH_3O.COOH$), or sulphosalicylic acid, has been found by J. A. Mac William (*Brit. Med. Jour.*) a very delicate reagent for albumin and all other proteids in solution. Following is the method employed: Take a small amount of urine (for example, 20 minims), preferably in a very small test-tube, and add a drop or two of a saturated watery solution of the reagent. If the urine is strongly alkaline, an extra drop or two of the acid should be added, and if no opalescence or precipitate occurs it is well to test the reaction with litmus-paper, and make sure that the urine has been rendered strongly acid. On adding the reagent, shake the tube quickly so as to mix its contents. Then examine at once. The occurrence of an opalescence or cloudiness immediately or within a very few seconds (for example, two to three seconds) is a test for proteids intermediate in delicacy between the cold nitric acid test on the one hand and the acetic acid and heat test (under favorable circumstances) on the other. The development of an opalescence some time after (for example, one-half to two minutes) is a more delicate test than even acetic acid and heat, and shows the presence of minute traces of proteid, which are probably insignificant, from a clinical point of view, as a rule. Next heat the tube to the boiling-point. If the precipitate or opalescence is caused by the ordinary "albumen "(albumen and globulin) commonly present in albuminous urine it does not disappear on heating, but, on the other hand, becomes markedly flocculent. But if the precipitate or opalescence is due to the presence of albumoses or pep-

tones, it clears up on heating (before the boiling-point is reached) and reappears when the tube cools.—*Western Druggist.*

NEWS AND MISCELLANY.

DR. G. FRANK LYDSTON.

Dr. G. Frank Lydston has been elected to the chair of Genito-urinary and Venereal Diseases, in the Chicago College of Physicians and Surgeons.

CHOLERA IN ASIA MINOR.

Reports as to the spread of cholera in Asia Minor have compelled the Porte to active precautionary measures for the watching of ships arriving from the Syrian ports.

DR. J. P. CROZIER GRIFFITH.

Dr. J. P. Crozier Griffith, Professor of Clinical Medicine in the Philadelphia Polyclinic, has also been elected Clinical Professor of the Diseases of Children in the University of Pennsylvania.

THE HISTORY OF TUBERCULIN.

In four acts:

Act 1—Eureka.
Act 2—Vici.
Act 3—Ave, morituri te salutant.
Act 4—De mortuis nil nisi bonum.
Epitaph—Fuit.
—*Medical Press.*

GLYCERIN SUPPOSITORIES.

Polubruiski (*Deutsche Med. Zeit.*) advises that glycerin suppositories are useful under the following conditions: 1. Constipation due to hardened fæces in the rectum. 2. Intestinal impaction in large intestines. 3. Pressure on the rectum from tumors. 4. To prevent straining at stool. 5. In children. 6. To hasten and increase ordinary evacuations.—*Western Druggist.*

THE ANTI-TOBACCO MOVEMENT IN FRANCE.

The French Society against the Abuse of Tobacco offers a prize of 300 francs (£12) for the best report of at least six unpublished observations of affections exclusively attributable to the abuse of tobacco. Full details must be given as to the etiology, symptoms, progress, and termination of the cases. Further particulars may be obtained from the President of the Society, 38, Rue Jacob, Paris.

DR. H. M. WHELPLEY.

Dr. H. M. Whelpley has been elected Professor of Physiology and Histology and Director of the Histological Laboratory of the Missouri Medical College. He has also accepted the office of Secretary of the faculty. The doctor is Professor of Microscopy in the St. Louis College of Pharmacy and Secretary of the Section on Materia Medica and Pharmacy of the American Medical Association.

FEMALE MEDICAL PRACTITIONERS IN JAPAN.

Since 1884, 36 women have passed the primary and 8 the final examination for the license to practice medicine. The examinations have in all cases been held at Tokyo, and the gradual progress of the movement is shown by the fact that while in 1884, only 1 woman passed the primary examination, the number of the successful candidates in 1889 was 15. In 1890, however, the number fell to 7. The number of those obtaining the license to practice has never exceeded 2 in any one year.

HEADACHES OF CHILDREN.

The headaches of school children, says Dr. W. S. Higgins in the *Peoria Medical Monthly*, are caused, not by over-study, but strain on the eyes caused by the white book paper used. Smoked eye-glasses will prevent the trouble, but children naturally dislike to wear glasses, and he now earnestly advises printing school books on yellow paper in blue ink, experiments having proven this the very best combination. For similar reasons white letters on black ground have also been recommended.

THE MODERN DIFFERENCE.

The doctors of the long ago,
With minds upon their patients' pain,
With ready lance were never slow
To bleed 'em in a vein.

The doctors of the present day,
Who count upon their patients "payin,"
Oft find their efforts—so they say—
To bleed 'em are in vain.

REMOVAL OF MOTHER-MARKS.

The *Allgemeine Medicinal Central-Zeitung* gives the following as very efficacious: Mix one part of tartrate of antimony with four parts of *emplastrum saponatum* and work into paste. Apply the mixture over the mark to be removed to the depth of one line (one-twelfth inch,) and cover with a strip of gummed paper or court plaster. On the fourth or fifth day suppuration sets in, and a few days later scarcely a sign of the mark can be seen.—*Dixie Doctor.*

AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

The American Electro-Therapeutic Association will hold its first annual meeting at the Hall of the College of Physicians, corner Locust and Thirteenth Sts., Philadelphia, Pa., Thursday, Friday and Saturday, September 24th, 25th, and 26th, 1891, under the Presidency of Dr. G. Betton Massey.

Physicians interested in the discussion of electricity in medicine, are invited to attend without further notice.

HORATIO R. BIGELOW, M. D.
Chairman Executive Council.
WM. H. WALLING, M. D.,
Secretary.
2005 Arch Street, Philadelphia.

MEDICAL TEMPERANCE ON THE CONTINENT.

In the struggle to check inebriety, which has of late so occupied the most cultured intellects on the Continent of Europe, very little has been done in the advocacy of abstinence. The prevailing idea, even among Continental members of the medical profession, has been that the increase of insanity and of other evils from drinking has arisen from the heavier alcohols, and that pure unsophisticated spirits, wines, and beers are really temperance beverages. A new departure has, however, been taken by a few of our Continental *confrères.* Professor Forel of Zurich, Professor Bunge of Basle, and Dr. Wilhelm Bode of Dresden, have established strictly abstinence societies in those cities, and these associations are now vigorously at work.—*British Med. Journal.*

"A COLD IN THE HEAD."

"A cold in the head;
What need be said?
Uglier, stupider, more ill bred;
Almost any other disease
May be romantic if you please,
But who can scoff
At a very bad cough?
If you have a fever you are laid on the shelf
To be sure—but then you pity yourself,
And your friends' anxiety highly excited,
But who do you suppose
Ever pitied a man for blowing his nose?
Yet what minor trial could be worse?
Unless it be reading this blundering verse,
Never fit to be written nor read,
No, nor said,
Except by a man with a cold in his head."
—*Exchange.*

REPORT ON HYPNOTISM.

The Committee of the British Medical Association, appointed to investigate the subject of hypnotism state that they regret that the time at their disposal has been too limited to allow of their completing their researches into a subject of such width and complexity. They are, therefore, as yet unable to express any definite conclusions to the Council. So far as their investigations have gone they seem to prove that the phenomena of hypnotism are such as to favor the belief that it may prove of service as a therapeutic agent when employed legitimately by properly qualified scientific persons.

They have no doubt, and they desire to give emphatic expression to this conviction, that the use of hypnotism by persons who are not so qualified, or without due precautionary restrictions, is greatly to be deprecated, and might properly be limited by legal enactment.

The Committee suggest their re-appointment.—*Brit. Med. Jour.*

MEDICINE AND PHYSICIANS IN RUSSIA.

M. Perfilieff, well known in Russia by his studies in public and social hygiene, and by his publications upon the desiderata of medical teaching and sanitary organization in Russia, speaks this time of medicine and physicians. He observes that the natural sciences are too sparingly and badly taught in Russian gymnasiums, and that, during their stay at the Faculty, the medical students are content with studying the theory of medicine without acquiring enough practical knowledge. The author complains that young physicians confine themselves to specialities as soon as they obtain their diplomas, so that there are no (or but very few) physicians qualified in natural philosophy.

The country has no need of female physicians; but these may usefully practice

medicine within restricted limits, well defined, or among the Mahommedan tribes in the empire, whose religion and customs are opposed to the practice of the medical art by men.

The sanitary organization of the empire and the sanitary conditions of life with most of the inhabitants leave much to desire. Mortality is much higher in Russia than in other countries. Of 1,400,000 male children born in 1855, within twenty-one years (in 1876—time of the conscription) 610,000, or 43 per 100 only, were found living. Among 1,512,202 boys born in 1862, in 1882 (time of the conscription) 777,769, or 51 per 100, were found living. Among 382,109 called in 1884, 71,607 men, or 19 per 100, were found, after medical examination, incapable for military service. The military incapacity is in most cases determined (in 32.9 per 100 cases) by affection of the bones, articulations and muscles.

These sad percentages need no commentaries and show that if France is threatened with depopulation on account of its feeble natality. Russia whose natality is considerable, is threatened especially by the physical degeneration of its inhabitants, a degeneration which was ascertained repeatedly on all sides through the latest statistical inquiries of Russian hygienists.—*Cin. Med. News.*

AMERICAN PUBLIC HEALTH ASSOCIATION.

The Nineteenth Annual Meeting of the American Public Health Association will be held at Kansas City, Missouri, Kansas, October 20, 21, 22, 23, 1891.

The Executive Committee have selected the following topics for consideration at said meeting:

1. Sanitary Construction in House Architecture.

(a) Heating; (b) Lighting; (c) Drainage; (d) Ventilation.

2. Railroad Sanitation.

3. Meat Supplies.

4. Milk Supplies of Cities.

5. Arsenical Papers and Fabrics.

6. Isolation Hospitals for Infectious Diseases in Cities.

7. Papers upon any of the subjects upon which special committees have been appointed.

8. Papers on Miscellaneous Sanitary and Hygienic Subjects.

All papers will be received by the Executive Committee subject to the requirements of the by-laws. Preference will be given, however, to papers upon the subjects selected by the Committee in making up the daily programme of the meeting.

All persons who propose to present papers at the next meeting of the Association, will be governed by the following by-laws of the Executive Committee:

"4. All papers presented to the Association must be either printed, type-written, or in plain handwriting, and be in the hands of the Secretary at least twenty days prior to the annual meeting, to insure their critical examination as to their fulfilling the requirements of the Association.

"5. If any paper is too late for critical examination, said paper may be so far passed upon by the Executive Committee as to allow its reading, but such paper shall be subject to publication or non-publication as the Executive Committee deem expedient.

"6. All papers accepted by the Association, whether read in full, by abstract, by title, or filed, shall be delivered to the Secretary as soon as thus disposed of, as the exclusive property of the Association. Any paper presented to this Association and accepted by it shall be refused publication in the transactions of the Association if it be published in whole or in part by permission or assent of its author in any manner prior to the publication of the volume of transactions, unless written consent is obtained from the Publication Committee.

"7. Day papers shall be limited to twenty minutes, and evening papers to thirty minutes, each."

Invitations extended to individuals to prepare papers, for the Association do not imply their acceptance by the committee, merit alone determining that question.

All communications relating to local matters should be addressed to E. R. Lewis, M. D., Chairman Local Committee of Arrangements, Kansas City, Mo.

Another circular will be issued before the meeting, giving transportation rates, hotel rates, etc.

Blank applications for membership can be obtained by addressing the Secretary, or Chairman of the Local Committee of Arrangements.

Officers: President, Frederick Montizambert, M. D., Edin.; F. R. C. S.; D. C. L.; Medical Superintendent Canadian Quarantine Service, Quebec; First Vice-Presi- Dr. Thomas F. Wood, Wilmington, N. C.; Second Vice-President, Dr. Henry B. Horlbeck, Charlestown, S. C.; Secretary, Dr. Irving A. Watson, Concord, N. H.; Treasurer, Dr. J. Berrien Lindsley, Nashville, Tenn.

Clinical Lecture.

DYSMENORRHŒA—MISCARRIAGE AND ITS SEQUELÆ—FIBROIDS OF THE UTERUS.

BY W. GILL WYLIE, M. D.,

PROFESSOR OF GYNÆCOLOGY AT THE NEW YORK POLYCLINIC—VISITING GYNÆCOLOGIST TO BELLEVUE HOSPITAL, ETC.

DYSMENORRHŒA.

Gentlemen.—The first patient I show you to-day, is a married woman thirty-five years of age, who has been married five years but has never become pregnant. She commenced to menstruate for the first time when twenty-two years of age and she has now been sick for several years. She complains of pain in the lumbar region, which is considerably increased during the process of menstruation, has frequent micturition, and complains of a lump in the epigastric region which sometimes rises up in the throat. Her urine is of normal consistency.

When a woman comes to your office with such a history as she gives, and one who has never been pregnant, the chances are that, in the large majority of instances you will find on digital examination, per vaginum, a small uterus, anteflexed either forward on the bladder, or backward on the pelvis. It seems to me that there is a great deal of nonsensical talk on the part of gynæcologists about the degree of anteflexion in any given case, for if the uterus is small, it is a little matter whether it be flexed forward to a great or small degree. In retroversion it does, however, make a good deal of difference, but in the case of anteflexion, it means simply that the uterus is weak and unable to sustain itself in its normal position in the pelvic cavity.

As I now proceed to examine this woman's uterus through the vagina, I find as I have already told you in anticipation, an anteflexion of quite a typical character, though the uterus is somewhat larger than is generally found in most cases of this kind. As the uterus is movable I cannot make out any disease of the tubes and ovaries, although the signs I find present in this case, point somewhat in that direction. I can distinctly feel the whole sigmoid flexure, and know that this woman's backache is due to the bearing down sensation which arises, not from the displacement of the uterus, but from displacement of the abdominal and pelvic contents which impart to the patient the sensation of uterine displacement. It is for this reason that the backache, which is a very common symptom in uterine trouble, is not always relieved when the uterus is restored to its normal anatomical position. We know from clinical experience how frequently the rectum is involved in these cases of uterine trouble, how common a symptom constipation is, how exceedingly common are fissures of the rectum and hæmorrhoids, and how hyperæsthetic is the condition of the rectum. We frequently find that this hyperæsthetic condition of the rectum is due to some ulcerative process in the intestine, and the tissues of the part are so extremely sensitive that the slightest amount of blood pressure, when the patient is in the erect posture, will commonly give rise to all the symptoms of uterine displacement. Then, let me impress upon you this one important fact that backache, when associated with uterine trouble, is often not due to the abnormal condition of the uterus, but derives its origin from some other source.

There is another pathological condition often overlooked by the physician, and which I wish to direct your attention to in this connection. In a great many cases of so-called uterine disease I find by digital examination of the uterus that there is very little, if any trouble, present in that organ. Perhaps it may be nothing more than a slight displacement, and you will find when you correct the displacement you will not cure your patient. The reason of that is that a great many

women, who lead sedentary habits of life, are of a gouty and rheumatic temperament, and many of these cases of obstinate and persistent backache are of gouty and rheumatic origin. So, acting on this hypothesis, when a woman comes to my office complaining of backache, I nearly always give her twenty grains of salicylate of soda, three times a day for three days, and then ten grains for the same space of time, three times a day, and then five grains three times a day, following this course of treatment with bicarbonate of soda. By adopting this plan in these cases of backache, you will be greatly surprised at the number of patients that you will be able to cure of their trouble.

Now, to return to the case before us. We have seen that this woman has flexion of the uterus, and have diagnosticated that by digital examination. We will now proceed to determine if she has dysmenorrhœa, a pathological condition some gynæcologists positively assert is usually found associated with flexion. I, however, hold that flexion has no sort of relationship whatever with dysmenorrhœa, and that the latter is nearly always due to one cause, and that cause is an abnormal condition of the lining membrane of the uterus, at or about the os internum.

The best proof of this lies in the fact that when you wash out the vagina with a bichloride solution, and having dipped the sound in an antiseptic solution, shaping it in the form of the uterine canal, and pass it into the cervix, it will pass about three-quarters of an inch without giving rise to any pain or feeling of discomfort on the part of the patient; but as soon as you touch the os internum with the sound, she will begin to cry out with pain. This sense of pain is pathognomonic of the existence of dysmenorrhœa in that woman's uterus, for if there be no dysmenorrhœa, there will be no pain when the sound is brought in contact with the lining membrane at the os internum. If you will bring twenty women with dysmenorrhœa to me I will demonstrate this pathological fact to your entire satisfaction in every instance.

When a woman comes to my office with those characteristic signs of dysmenorrhœa, and I find that the uterus is movable, having excluded a diseased condition of the tubes and ovaries, my treatment consists in dilatation, that is in introducing the blades of the dilator into the cervical canal, separating them three or four points and then withdrawing them. I next make an application of pure carbolic acid through a cylinder tube to the diseased portion of the uterine membrane. In that way I secure perfect drainage and bring about a physiological change in the diseased lining membrane of the uterus. If you want to be a little careful in your procedure, you may apply against the cervix a little iodiform by means of a powder blower, as the speculum is withdrawn. The first dilatation should be made at the home of the patient and she should be kept in bed until all the mental and physical disturbance incident to the operation has completely subsided. I would advise you not to make more than two intra-uterine applications in any one case, and if you make the application at a period of time near the menstrual discharge you may cause trouble, and arrest the function of menstruation. By this simple procedure you can cure the dysmenorrhœa in nearly all cases that apply for treatment suffering from this pathological condition.

There are some of these patients whose uteri are markedly indurated, the uterine tissues exceedingly sensitive, and the patients extremely nervous. Under these circumstances, it may be necessary to give ether, and I would then advise you to use the curette in addition to the application of carbolic acid to the endometrium. In the use of the curette, have a good steel instrument and put in a hard rubber drainage tube 2¼ inches in length, and about the size of an ordinary lead pencil, slightly bulbous at the point, and curved so as to approximate the normal physiological curve of the uterine canal. At its proximal end, it should have a button shaft so as to rest in the cul de sac, with a deep slot running from one end to the other; this slot is to act as a medium for drainage. The slot should equal in calibre, at least one-third of that of the tube itself. This tube should be permitted to remain in position in the canal for a week, a roll of iodoform gauze being introduced into the vagina to maintain the tube in its proper position. Then put the patient in bed, and have her remain there for a period of one week. On the third day you can remove the iodoform gauze, wash out the vagina with a bichloride solution, replace the gauze, keeping it in for three or four more days, and at a later period you may use a warm douche or two. Then take out the drainage tube and have the patient use boroglyceride after the next menstruation. Two or three days after she has ceased menstruating, examine her in Sims' position, wash out the vagina, take a clean sound and pass it into the uterus. If you can pass it freely into the uterine cavity without causing pain

or hæmorrhage, the dysmenorrhœa of your patient will be cured.

By these measures, I claim you cure nine out of ten cases of dysmenorrhœa that may present themselves to you for treatment, within from eight to ten weeks. Where, however, the general condition of the patient is very bad, or becomes bad in the spring, in some cases only a temporary cure will be brought about, and the next spring when the general condition of the patient has deteriorated, uterine catarrh will again return, and with it the dysmenorrhœa.

These produces viz., curetting, divulsion and drainage, may appear to you to be a very simple measure, but in the vast majority of the cases operated upon in this manner by you, you will fail to secure a good result unless you are particularly expert in the use of the instruments you employ. Up to eight years ago in this city, most of the cases treated in this way where the uterus presented an indurated appearance, failed to bring about a good result, because the operation did not succeed in dilating the os internum. In dilating the os internum, the tendency is for the instrument to slip off. When an operator takes a tenaculum and holds the uterus well down while dilating the os, you can be assured that man does not understand the very first principles of dilatation of the uterine canal, and will not consequently succeed in bringing about the desired result. The cervix will simply become elongated, and the tube rests in the cervical canal, instead of going into the uterine cavity. Fifteen years ago, I took the trouble to go around and see the most eminent men in this country perform this operation. And I have seen Marion Sims himself fail two out of three times to get the tube into the cavity of the uterus. I drew his attention to this elongation of the cervix, I have just spoken of, and in a case where he failed I took the curved dilators myself and got them well through. I dilated the os internum and succeeded in introducing a sound an inch farther in than he could. When I put his glass plug through the os internum, it was held there so firmly that it could not, without some difficulty, be drawn out.

Not long ago, at a meeting of the Obstetrical Society of this city, I heard a very eminent gynæcologist get up in the meeting and make the statement that he never cured a single case of dysmenorrhœa or sterility by dilatation or divulsion. I replied that he did not cure them, because he did not know how to perform the operation properly and efficiently, and the man who knows how to do this operation thoroughly, will succeed in securing the desired result in nine cases out of ten.

MISCARRIAGE AND ITS SEQUELÆ.

The next patient I present to you is a married woman, 23 years of age. She has been married three and a half years, and has had but one child born, a year after her marriage. She has had four miscarriages and did not menstruate previous to her marriage.

We learn from the history of this woman that she gave birth to her child one year after marriage, and had her first miscarriage nine months later. She had her second miscarriage, four months after her first, the third, six months after the second and the fourth, about five months after the third. She had pain in the left ovarian region, and pain in the back, which continued up to a few months ago, when a laparotomy was performed and an ovarian cyst removed from the left side of the abdomen.

Among the better classes in New York, the form of uterine disease that generally prevents itself to the gynæcologist, is the arrest of development of that organ, while, among the poorer classes, and especially in the case of patients who present at clinics like this, the chief trouble seems to be due to miscarriage and its sequences. These generally take the form of chronic endometritis, subinvolution, laceration, displacements and sterility. A great many of these sequelæ have their origin in want of cleanliness after labor or miscarriage, an ignorant and unclean mid-wife being the obstetrician employed in very many instances. This patient represents a typical instance of this.

As I examine this woman's uterus I find that it occupies its normal position in the pelvic cavity, though it is, perhaps, a little larger than normal. I can detect no signs of a tumor on either side, except that I feel on the left side a mass which appears like a prolapsed intestine.

I wish, in this connection, to say a word on miscarriage. As to the cause of this condition, of course, it may have its origin in a number of sources. Excluding mechanical causes, such as induced criminal abortion, syphilis is one of the most frequent. A woman who has been infected with syphilis, is liable to have a miscarriage any time after the second month, though it is generally more apt to go on to the fourth, fifth, or sixth month.

As to the local conditions that cause mis-

carriage, displacement backward plays a very important part. If you have a retroflexion of the uterus, the fundus may be caught in the hollow of the sacrum, and as the uterus grows larger, the fundus doubles under the sacrum, as a result of this pathological process, the fœtus is squeezed out of the uterine cavity.

Another cause of miscarriage is laceration of the cervix, with eversion of the os. You may get, as a result of this condition, an active catarrhal disease of the cervical canal starting from a latent process, as the uterus becomes congested, and as pregnancy continues, this cervicitis becomes so active as to extend into the uterine cavity and give rise to an abortion. These cases are frequently found associated with membranous dysmenorrhœa. These are the most frequent causes of spontaneous abortion in women.

Where women have had six or seven abortions, it is very rarely you can cause the pregnancy to go on to full term by simply curing the uterine cervical trouble. There are many cases of spontaneous abortion, where if you relieve the congestion by means of boroglyceride applications during the first three or four months of pregnancy, the patient may go on to full term. In the case of retroversion, when the woman becomes pregnant, by putting in a pessary so as to prevent the uterus from being kept in the hollow of the sacrum, that organ will go on enlarging, and after the fourth month is past there will then be no risk of an abortion taking place.

I always make it a habit in practice to examine a woman the second week after her confinement to determine whether there be any abnormal condition present in the uterus or not. If the lochial discharge continues up to that time I place the woman in Sims' position, push the uterus up if it be necessary, and use boroglyceride cotton pledgets. By these measures, you will be certain to secure the establishment of involution and get a firm contraction of the uterine ligaments. I make it a rule now to take no case of confinement unless I have the privilege of superintending the condition of the patient for at least six weeks after delivery. If the perineum be ruptured, I always sew it up, and you will in vain search for any pathological condition following a woman after labor or miscarriage in any case that I have treated.

The doctor asks me whether there be any danger in the use of boroglyceride pledgets in the treatment of uterine disease. I would say, in answer to that question that there is absolutely no danger whatever, and instead of it having a tendency to abortion, it, on the contrary, usually prevents it, if there be such a condition threatened. I generally use boroglyceride in case of threatened abortion, and generally with very good result. The physiological action of this drug is to produce a free watery discharge from the vagina. In the case of nausea in women, I use boroglyceride till the os is soft, and it is surprising to see the beneficial effect produced by this simple measure. If the nausea is not relieved by this means, I dilate the cervix below the os internum, and by this measure, I will guarantee to cure any case of nausea and vomiting, if the period be not too near menstruation ; I use boroglyceride tampons twice a week to soften the os, then I take the dilators, introduce them three-quarters of an inch up the cervical canal, and dilate freely. When you have dilated the os sufficiently so as to be able to introduce your index finger, you will be able to cure any case of nausea and vomiting that may present itself to you for treatment.

There is another point, in this connection, I wish to impress upon your minds, and that is, when you first begin to treat these cases, in this way, you will be sure to fail in curing your patient. My views about the ætiology of nausea and vomiting in women are that these pathological conditions are due to either a diseased or indurated condition of the cervix. When the tissues are normal and the cervix swells and becomes large, there is then no pressure on the nerves of that region, but when the cervix is the seat of a pathological process, the diseased follicles and glands that are located there, become enlarged, and when the time arrives for a physiological enlargement of the cervix it does not grow large, but causes pressure and gives rise to reflex symptoms. I have been frequently called in consultation to see cases that were utterly hopeless and where an abortion had been advised by the attending physician, as the only means of relief, but where I dilated the os, and brought about a complete cure of the symptoms.

FIBROIDS OF THE UTERUS.

The next patient is a married woman 48 years of age, who has been married 26 years. She has had nine children and one miscarriage, the last child being born six years ago. She had two uterine polypi removed 6 months since, and had some discarge from the vagina three days ago, she having ceased menstruation for some years.

It is always a cause for some suspicion of

pathological process going on in the uterus of a woman who had ceased menstruating, as this woman has and then for the flow to go on again. As I examine the uterus of this woman I find it somewhat enlarged, and as I pass my finger along the vagina, it comes in contact with a small fibroid of the uterus. In a case like this, the hæmorrhage this woman complains of ought to be controlled by the use of the curette and removing any small fibroids that may be found in the uterine cavity. If curetting does not succeed and the hæmorrhage still persists, the proper course to pursue then would be to remove both tubes and ovaries, and put an end in that way to any further trouble.

This question of fibroids brings up the subject of electricity in the treatment of these morbid growths. My belief is simply this, that if you employ electricity in sufficient quantity and with sufficient force to act as a destructive agent, you can stop the hæmorrhage and destroy these growths, but in doing so, except in rare instances, you run greater risk than if you were to resort to operative interference for their removal. If electricity stops hæmorrhage, it does so by practically destroying the mucous lining of the uterus. If it diminishes the size of a fibroid, it acts as a destructive agent by interfering with its growth and vitality. Who has ever heard of a tumor on the hand or other external portion of the body cured by electricity unless it was sufficiently powerful to destroy the skin or adjacent tissues. Fibroids cured by electricity in young women grow more rapidly after you have stopped the electricity than before its use. My experience in the use of electricity in these cases of fibroids has been, that it has seemed beneficial in women who are near the menopause, and it is doubtful whether this beneficial effect was due to the electricity or to the menopause.

In a case like this woman, I would prefer the use of the curette to that of electricity; for I know by practical experience that I can stop the hemorrhage, with much less risk, and certainly less trouble in the future, than if I were to employ electricity to produce the same effect. My main objection to the use of electricity in these cases is, that the uterine cavity is lined with follicles and glands, and by the use of electricity or any other caustic agent, you shut up the mouths of these glands, and follicles, deprive them of drainage, and in this way give rise to the establishment of tumors. As a result of this condition of affairs, you produce in the woman reflex symptoms of a much more distressing nature than the original trouble for the elimination of which you employed the use of electricity.

COMMUNICATIONS.

SHORT CONSIDERATIONS ON INTUBATION IN CHILDREN AND ADULTS, AS ADOPTED IN ITALY.

BY PROFESSOR F. MASSEI, M. D.,

NAPLES, ITALY.

Although intubation owes its birth to America, and is a subject that is well known and frequently illustrated in that country, I think that its interest will, in no way, be diminished by a slight contribution of my own personal experience, which embodies the results that have been secured in Italy by this new method. In presenting this contribution to the profession in America on the subject of intubation of the larynx, it will, I believe, represent the best homage I can offer to the genius and ability of its distinguished inventor, Dr. O'Dwyer.

The value of intubation in croup ought to be better appreciated by specialists in diseases of children than it has been, but it has happened, on the contrary, that the first who have given this new method a trial have been the laryngologists.

Great difficulty was experienced in the practical introduction of intubation into Italy, and I myself was most firmly opposed to it on purely theoretical grounds, being of the opinion that intubation, although by no means a bloody operation, was not always free from danger. My own researches and experiments have been, I am glad to say, mainly instrumental in dissipating these groundless fears and establishing on a sound basis the credit of intubation in Italy. I now rank myself among its warmest and most steadfast advocates.

It is worthy of mention that the unjust comparison that has been instituted between intubation and tracheotomy in croup, did not fairly reflect the virtues of the former. Our sincere gratitude is due to Dr. F. Egidi, of Rome, who, despite my strenuous opposition, was the first to introduce intubation into Italy. Unhappily, in Rome the malignant character of croup has given very bad results.

Dr. Egidi, a specialist of long and active practice, is a most determined and avowed

partisan of intubation. He has shown by clinical experience that the best results were not secured by tracheotomy in croup. He performed intubation and tracheotomy, and death resulted in 90 per cent. of the cases, with the general symptoms of poisoning, even in cases of primary croup favorable to a good result. In Naples I was afforded a good opportunity for experiment. In eleven intubations in children, nine of them being for croup, I have had five successes, and these occurred in so striking a manner that the profession began to look favorably upon intubation, appreciating its great value in this disease.

I will cite a few, brief clinical cases, as they have occurred in my practice.

NATURE OF THE DISEASE FOR WHICH INTUBATION WAS PERFORMED.

In my first eleven cases in children, intubation was performed for croup in nine instances; for stridulous laryngitis in two. In the first case, intubation proved in a striking manner the fact that when it is possible to lengthen the duration of the disease in the so-called primary croup, we may watch the development of the characteristic signs of diphtheria, such as the appearance of the diphtheritic patches in the throat, the skin, diphtheritic paralysis, albuminuria, etc.

The views which I have for a long time entertained with regard to the identity of croup and diphtheria, will, in all probability, find a confirmation in some of the bacteriological researches that have been recently made in Italy. Although not as yet published, they go to prove that the bacillus of diphtheria has been found also in membranes of the so-called typical primary croup.

The two cases of stridulous laryngitis have convinced me that the anatomic-pathological impairment is represented by an acute epiglottic laryngitis (chorditis epiglottica acuta), and that the disease may easily produce death by suffocation, if intubation or tracheotomy be not performed. These cases show also that in children we have the right to separate an acute narrowing of the larynx of non-infectious character, (laryngitis stridulous) from those diseases in which a simple catarrh is present, and the presence of a thick, mucus exudation, is the cause of the intense dyspnœa which frightens families, but disappear after simple treatment. Every catarrh of the larynx in children may easily render the glottis smaller, and when mucus is added to that, a spasm is apt to result; but in the acute epiglottic laryngitis we have present a morbid process which is very similar to croup, and time only can settle the question. Hence, we can understand why it is that in some eminent French publications, the symptomatology of stridulous laryngitis is presented in such a manner as would lead us to conclude there was an intermittent spastic danger, which is not really the case. From this we can see the importance of distinguishing in young children a severe form of simple laryngitis from a mild one, both being accompanied by stridor, the one in a constant, the other in an intermittent manner.

Acute epiglottic laryngitis not only represents a danger in itself, but also is the first stage of an inflammatory condition which may extend to the lungs. One of my intubations for this disease ended fatally on account of a double attack of pneumonia. I do not deem it proper to explain this result on the ground that pneumococci, which are found in the saliva physiologically, may descend through the tube into the lungs, first, because pneumonia had developed before the intubation had been performed, and second, because I have seen this condition present before I had performed intubation, viz., as a result of tracheotomy, or as a result of the ordinary treatment of the local applications of ice over the chest, third, because in the case of adults who have been intubated, we never meet with a pneumonia following this procedure. The pneumococci may reach the lungs in such a variety of ways that it is not essential to insert a tube in the larynx for their migration into the lungs.

The eleven intubations above referred to, were performed by me in children not more that five years of age, and not younger than eleven months. Three were twenty-three, eighteen and eleven months of age respectively; that is these three were under the age of two years, a period of life which gives us bad results in tracheotomy, and this, notwithstanding, I can record one successful case. Two other children were twenty-seven and twenty-nine months old respectively, who were suffering from croup, and in one, recovery took place, although it was a secondary croup.

THE TIME DURING WHICH THE TUBE REMAINED IN PLACE.

The tube, when recovery took place, that is, when the stenosis of the larynx had entirely disappeared, remained *in situ* for a period no longer than six days, nor shorter than thirty-two hours. During this period,

it was sometimes coughed up and sometimes taken out to be cleaned. It is worthy of mention that these extreme conditions existed in cases of stridulous laryngitis, one of which ended in death, and the other in recovery.

In two cases of croup, the tube remained *in situ* for a period of five days, in one case, only 63 hours. In two instances (croup and stredulous laryngitis) although death took place when the tube was removed, no sign of narrowing of the larynx was present.

RESULTS.

The result of my eleven intubations in children has been as follows: five recoveries, six deaths, and more particularly in nine cases of croup six recoveries; of two cases of laryngitis stridulous, one ended fatally, and one recovery took place. In the five cases that ended fatally I may mention the fact that the intubation was done by way of an experiment, as the patients were all in a very bad condition and presented no hope of recovery. Twice, the tube was coughed up, and I had not been advised of the fact until it was too late to re-introduce it. In only one instance did death occur from pneumonia, and in this instance, the breathing through the larynx was perfectly free.

The same occurred in a case of stridulous laryngitis, so that so far as the restoration of breathing was concerned intubation fulfilled every possible indication. This fact is in itself sufficient to prove that a comparison between intubation and tracheotomy in croup is not practicable. Intubation, in many instances, is sufficient to ensure free breathing through the larynx. When this is not possible, we have always sufficient time left us for the performance of tracheotomy, but in view of the superior advantages of intubation over tracheotomy (it being less dangerous and the possibility of removing the tube in a shorter time without making a wound) it becomes a duty in the treatment of croup for the physician to employ the simple procedure of intubation. Tracheotomy always remains as a last resort, particularly in cases where there is a trachal-stenosis or propulsion of a false membrane down the trachea.

We must not, however, forget that the last modifications of O'Dwyer may meet with just such inconveniences as these I have referred to and I cheerfully take this occasion to inform the profession that my colleague, Dr. Egidi, has made a very useful modification of the tubes. Taking into consideration the fact that the short, thick tubes of O'Dwyer, remained with difficulty *in situ*, that the long one had not sufficient room for the issue of false membranes, and finally, that the introduction of the tube may, in advanced stages of the disease, provoke apnœa, he employs now a tubulated introduction (in imitation of Bouchius camela) and thus the operator is not only sure to follow the right path, but the patient can freely breathe the very moment of its introduction. Egidi's tubes are shorter than those of O'Dwyer's and larger than O'Dwyer's short tubes, but they are oval in shape and remain readily in position. One set is sufficient, in all cases, and the operation is thus very much simplified.

IMMEDIATE DANGERS OF INTUBATION.

The immediate dangers of intubation, apnœa, syncope, etc., may be avoided by an early interference, eliminating by such means every inconvenience. Intubation is a simple operation, when performed as soon as the signs of a stenosis are present, and when the usual treatment has not been sufficient to avoid its employment.

The Thread.—This may be allowed to remain *in situ*, if precautions are taken that children do not snatch it away. This I prevent by enveloping the hands of the patient with a kind of pocket glove. When the thread is *in situ*, an assistant is always at hand to take out the tube, when it is occluded, and the same operator can do it in a simpler manner and shorter time than with the extractors, whose employment, as every one that has practiced intubation can testify, is difficult, and even more so when the child is dying by suffocation. The difficulty added to deglutition by the presence of the thread is not great, but we ought not to forget that the thread, although very strong, is at times broken by the teeth of the patient.

Deglutition.—As far as swallowing is concerned, I have seen in many instances that children were unable to drink satisfactorily, but in all cases, when the tube remained in place some days, they swallowed quite well. In general, I have taken care to select large tubes and to push them well down in order to prevent any obstacle to the function of the epiglottis, because I am personally convinced that this must be the real cause of the difficulty experienced by patients in swallowing. I have never permitted children to drink unless in my presence. I begin with a little coffee or tea, and afterwards give the glass, although in some instances, the first method has not proved as satisfactory as the second. In general I am able to feed my little patients with semi-solid food (pap, milk, wine,

broth, etc.,) and was never obliged to make use of the œsophageal catheter, a simple but not very practical expedient, and a very troublesome one withal. When the patient complained of thirst, I several times preferred to remove the tube, temporarily, and introduce it again; although even without the tube, some time after it remained *in situ*, deglutition was not free from difficulty.

Pneumonia—As a last consideration I may be permitted to speak a few words on pneumonia, a subject of great importance in this connection, and which not infrequently is the cause of death. I believe it has been demonstrated by post-mortem that pneumonia does not depend on the entrance of food into the inferior tract, now that the tube affords a readier access for the entrance of the pneumococci. (See s. 1.)

Pneumonia in croup, as in stridulous laryngitis, is a common complication, a consequence of, or a new localization of the disease, which in both instances may be considered to be of microbic origin, the Lœfflers' bacillus in diphtheria, the pneumococci in the latter case.

I cannot leave this interesting subject without adding a few words on intubation in adults. Since the valuable communication of Prof. Lefferts was made to the International Congress of Berlin on Intubation of the Larynx in Acute and Chronic Syphilitic Stenosis, I presented the great success of the new method, and, in fact, as soon as I was furnished with tubes for adults through the kindness of Prof. Lefferts, I began my experiments and with wonderful success. I will briefly refer to these cases. They are few in number but very instructive.

1st Case—A girl, 16 years old, very slender and pale, had a contagion on the lips when 5 years old, which was followed by the symptoms of constitutional syphilis. She applied to me for treatment, suffering from severe dyspnœa. On laryngoscopic examination the left half of the larynx was found to be infiltrated; the rima glottidis reduced to a few millimetres in diameter. Hypodermic injections of bichloride of mercury for two days resulted in no improvement, and the girl feared death from suffocation. Intubation was performed and the tube was permitted to remain for six hours in position. When taken out, her breathing was much better. The treatment was continued at intervals and the patient is now considered cured.

2nd Case—A young woman 25 years old whom I had previously on several occasions treated for severe attacks of nasal and laryngeal tertiary syphilis. She lately applied to me with symptoms of extreme laryngeal stenosis. She was in the sixth month of pregnancy and showed on laryngiscopic examination signs of gummous infiltration of the vocal cords. Intubation was readily performed and repeated for many days. The tube remained in place for from 6 to 8 hours daily. The improvement in this case also was marked. The general and local treatment was kept up, being suspended only for one or two days.

3rd Case—A man, 32 years of age, presented the symptoms of pacchy-dermi-laryngitis in the arteriod space, and in consequence, developed a marked narrowing of the larynx. By means of the curette and Schrotter's tube I avoided a tracheotomy which I was prepared to do the same day. The patient greatly improved, but in order to continue the dilatation, I used the common intubation tubes and a large one was well supported, although introduced with some difficulty and easily coughed up. This was owing to the fact that when dilatation was done, the tube was not well retained *in situ*. The effects produced after a few hours were indeed marvelous.

4th Case—A young man, 17 years of age, was suffering from chronic epiglottic laryngitis. He improved a little under the use of iodide of potassium and revulsives, but on account of an acute attack of catarrh, the stenosis increased and tracheotomy was urgently demanded. The patient lived at a 17 hours ride from Naples, and when I reached his home, I found him in a very bad condition. Intubation was easily performed and the tube was permitted to remain *in situ* for 12 hours. After this time I removed it and noticed a marked improvement of his local condition. The tube was reintroduced and then left in position for 8 days; at the end of this time, the patient was in a condition to come to Naples and follow out the local treatment under my personal supervision. He could swallow both solids and liquids from the moment of the first introduction of the tube.

In referring to these different cases, I have made no allusion to the difficulties, selection of tubes, and the time they may remain in place, as these have been very clearly and ably stated in Prof. Lefferts' original pamphlet. There is no reason to doubt that in the second case of laryngeal syphilis, as in the last one, tracheotomy was the only course to be adopted to save the patient's life. Intubation has been found to be an excellent substitute for tracheotomy with all the added

advantages of its simple and rapid mode of action, in contrast with the danger and difficulty of tracheotomy. My patients were all able to swallow solid food, and one of them even liquids, although their condition was one of great danger. After the first application of the tube, it was possible in two cases, to take it out, allow them to swallow and rest without danger of suffocation. I understand that this is not possible in all cases, and that time is the best guide to determine whether the patient can swallow well or not, as Prof. Lefferts states. I can now prophesy that intubation in adults will soon meet with larger indications, and principally in acute stenosis of the larynx, (œdema, angio-neurotic œdema of Strübing, phlegmonous laryngitis, primary erysipelas of the larynx, &c.) and even in other cases of chronic stenosis when it can be determined from laryngoscopic examination that a way, though a very narrow one, exists for the tube to take a right and firm position.

It is scarcely necessary to bear in mind that in the case of adults I have always performed intubation under the guidance of the laryngiscope, and it was possible to take out the thread and remove the tube in a simple and ready manner by means of the extractor.

I submit this brief communication as a sincere homage to Profs. O'Dwyer and Lefferts, to both of whom humanity and science are greatly indebted.

INDIGO AS AN EMMENAGOGUE. *

BY J. L. JONES, M. D.

BELLS, TENN.

Indigo was introduced to the notice of the profession as a remedial agent, and at first chiefly employed by the German physician, from whose statements our knowledge of its physiological action and therapeutical application was derived. It is odorless and tasteless, and may be given in doses of ʒss. to ℥ss. three times daily. The great difficulty in administering it is occasioned by the nausea and vomiting which the crude drug produces when given in very large doses. My attention was first directed to it as an emmenagogue in July, 1887, from an essay published in The Medical and Surgical Reporter, of Philadelphia, read by Dr. S. T. Yount, of Lafayette, Ind., before the Tippecanoe county Medical Society. He says his attention was directed to it accidentally, he being called to remove a retained placenta in a case of abortion at three months. Inquiring of the lady what she had taken to produce the abortion, he was told that she had taken indigo in teaspoonful doses three times daily for ten days; that she had taken it several times before this, always with satisfactory results. She informed him at the time, it always produced great nausea and watery discharges from the bowels. Acting on the suggestion offered by Dr. Yount's paper, I have used it in many and various cases. My first case was a young lady twenty years old, who had not menstruated in five months. I had been treating her for three months with our usual remedies without any effect from anything I gave her, so I made up my mind at once to give indigo a trial, which I did with the following result: I ordered indigo ℥ij., subnitrate of bismuth ℥ss., well mixed. She had taken ½ teaspoonful in ½ of glass of water three times daily for nearly four weeks, when one day I was sent for in great haste to see my patient. On my arrival I found my patient on the bed and comfortable. I asked why I was so hastily called; I was told by the mother that her daughter had been walking in the garden, when without any pain or warning of any kind, she began to flood. There was a gush, followed with a gentle flow that lasted only for a little while. In five days she was well, and has not suffered from amenorrhœa since.

I have since then used it in thirteen cases with but one failure, and that lady proved to be pregnant. To test its effects I have given the remedy in the amenorrhœa of phthisis, and have always had a definite result, namely, the appearance of the menses, the menses stopping when the remedy was stopped. After using the remedy for twelve or fifteen months, I procured from Mr. O. G. Zers, an apothecary of Lafayette, Ind., a concentrated extract, as he called it, five grains equalling twenty-six grains of the crude drug. The effects with the crude drug and the concentrated extract, is the same, except that the nausea does not occur when the extract is used. The menses come on painlessly and very suddenly. There is no warning given. In seven cases the effects occurred in about two weeks after the treatment was begun; in five, I had to continue the treatment four weeks; in the other, by the time she had taken the remedy three weeks I found out beyond a doubt my patient was pregnant; however, I had no abortion in this case, my patient went on to full time.

My last, or thirteenth case, is a young lady

* Read before the Tennessee State Medical Society, April 15, 1891.

twenty-six years old, and the very picture of health now, and also when her menses fail to make their appearance. She can, and has gone four months without menstruating, and never have a pain or an ache, never complaining, only saying she was afraid of going into consumption if her menses did not become regular. I have treated her three months with our usual remedies without any effect whatever, but I can give her indigo ten days, and her menses will come on and be regular for several months.

During the administration of the drug the os uteri becomes soft and patulous, admitting the end of the index finger. There is often a serous discharge from the vagina. The urine becomes of a brownish green color, and offensive odor. The stools are watery and offensive.

To summarize; indigo is an emmenagogue of decided value in any case. Dr. Yount says, it should not be given to pregnant women; it should not be given where there is an irritable stomach; it should not be given where there is a history of previous pelvic inflammation; it should not be given where there is marked cerebral anæmia. However, I have never noticed the effect of indigo in any of the above cases, except the first (pregnancy) and that woman went to full time after taking indigo three weeks. The concentrated extract may be given in doses of five to ten grains, three times daily. The powder of the crude drug should be given mixed with a small quantity of bismuth subnitratis, and the patient should drink a little whiskey or sherry wine afterwards. In cases in which it is given for a long period, give Tr. gentian. comp. after each dose. Give the concentrated extract in capsules mixed with extract of gentian and bismuth subnitratis.

MILK AS A MEDIUM OF CONTAGION IN TYPHOID FEVER.[1]

BY EVERETT J. BROWN, M. D.,
DECATUR, ILLINOIS.

I wish to report a number of cases of typhoid fever occurring recently in the city of Decatur, in which the origin of the disease could be directly traced to the milk supplied by one dairyman, in whose family there existed two cases of the disease. Within two months after the development of the first case in the family of this dairyman, there appeared in rapid succession five other cases of the disease, in as many different families, all of which derived their milk supply from this dairy. The families in which the disease appeared lived in portions of the city widely distant from each other, so that there were no local causes affecting them all alike; another point of importance was that there were scarcely any other cases of the disease in the city at that time.

We can safely say then that the milk of this dairyman was infected, and that it was the medium of contagion for the disease. Our first thought would be that the milk supplied to these families had been diluted with polluted water, or at least that the milk utensils had been washed with water containing the disease germ; this could not have been the case, however, for on the premises of the dairyman there were no wells or cisterns in use, the water used by the family being derived from the common water supply of the city, and as this is the almost universal drinking water of the town, it is evident that the milk was not contaminated by it, even if diluted with it.

On inquiry it was found that the person having charge of the milk of the dairy—such as the straining, etc.—also assisted in the care of the two members of the family sick with the disease—washing their clothing and bed linen, and preparing their food; this I think, explains the manner in which the milk became infected: by the failure of this person to observe the ordinary acts of cleanliness, the poison was undoubtedly carried directly from the sick room by means of the hands or articles used in the room, to the milk or the vessels containing it; it is what Dr. Cyrus Edson calls "digital infection," and is regarded by him as a very frequent manner in which the disease is transmitted, and explains many cases, the origin of which seems obscure.

In investigating the causes of typhoid fever, we can safely accept three propositions as thoroughly proved:

1. That the exciting cause of typhoid fever is a specific organized pathogenic germ, called by Eberth the "bacillus typhosis," which is constantly found in the various organs and fluids of the bodies of persons suffering from the disease.

2. That the germ is invariably derived from a previously existing case of the disease, and is never developed *de novo* in filth or decomposing organic matter as was formerly supposed.

3. That "the poison is always tangible,

[1] Read before Illinois State Medical Society, May 1890.

and like cholera, can never infect through the medium of the atmosphere, but must enter the stomach of man, in his food or drink.

It is probable that the large majority of the cases of typhoid fever are due to the use of either polluted water, milk, or meat, although any kind of food may become infected. In milk the typhoid germ is in its element; it there finds the very best possible medium for its rapid growth and reproduction; it is in a culture fluid in which it finds all the conditions necessary for its development.

The presence of the poison in water and in ice is easily accounted for, especially in a neighborhood where cases of the disease have occurred, and where the ordinary precautions, such as the disinfecting of the discharges, etc., have not been taken; its presence in milk or other food, except in those instances where polluted water has been added to these, and, provided we reject the theory of atmospheric contagion, can only be accounted for by assuming that the poison has been carried directly from the sick persons to this food; the hands, the clothing, or the many articles used about the sick room may be the carriers of the poison. A nurse having charge of a typhoid patient cannot possibly keep the hands entirely free from contamination; the sputa as well as the excreta may infect the fingers; dishes, knives and forks, door-knobs, etc., may receive enough of the poison to infect the hands of those who subsequently touch them.

That typhoid fever is a preventable disease, there can hardly be a question, and if it could only be universally regarded as such, and be placed in the same category with the other preventable diseases, such as septicæmia, pyæmia, erysipelas, etc., and if the physician would practice the same scrupulous cleanliness—the same antisepsis—that is practiced by the surgeon, much would be done to eradicate this terrible disease. The typhoid germ is very easily destroyed by the ordinary means of disinfection, such as the use of heat, carbolic acid, and bichloride of mercury; in fact, antisepsis about a typhoid patient is as easy of attainment as it is in a surgical case.

Many rules have been laid down for the prevention of the disease and for checking its spread, but they may all be summed up in two short sentences:

1. Complete and thorough disinfection of all the discharges from the patient.
2. Absolute cleanliness.

HOW TO USE MYDRIATICS.

BY EDWARD JACKSON, M. D.

PROFESSOR OF DISEASES OF THE EYE IN THE PHILADELPHIA POLYCLINIC; SURGEON TO WILLS EYE HOSPITAL, ETC.

The present purpose is to discuss methods, not indications, for using these drugs; but, in passing, it is worth repeating, since it is so often forgotten, that remedies of this sort are too powerful to be used indiscriminately. If one has not been able to make a positive diagnosis in a case of ocular inflammation, to clearly recognize the indications, and to definitely exclude the contra-indications for one of these drugs, he should let them alone, and confine his hit-or-miss prescribing to such agents as boric acid, or weak solutions of common salt, whose power for harm is really very slight.

These drugs are applied to the eye for their direct influence on the cornea, iris, or cilinary body. In either case they must be absorbed through the cornea, the lymph streams of which are in close relation with those of the anterior chamber. Any portion of the drug that may be absorbed from other parts of the conjunctival sac is carried into the general circulation without coming in contact with the structures it is intended to influence. Any solution placed in the conjunctival sac is almost immediately diluted by the lachrymal secretion present; only the part with which it first comes in contact receives it of full strength. Now, if the amount of fluid instilled is very large as compared with the amount of tears diluting it, the dilution is of very little importance. But instillations of large amounts of mydriatic solutions are not advisable, because they give the maximum of absorption into the general circulation with the maximum of effect on the eye, And one thing to be constantly guarded against in the use of mydriatics is the excess of constitutional action. Therefore, a mydriatic solution used in the eye should be instilled so as to come immediately in contact with the cornea while of full strength; that is, it should be placed at the upper margin of the cornea, allowed to flow over the surface of that membrane, and the closure of the lids prevented as long as possible, to allow absorption to occur before the fluid is swept away by the movements of the lids and diluted with the tears.

Instilled in this way, the concentration of the solution when it comes in contact with

the corneal tissue, and consequently the amount absorbed, may be ten times as great as if the single drop of the same solution had been placed in some other part of the conjunctival sac. Thus applied, a very small drop of solution suffices to bathe the whole cornea. A dropper giving a small drop is therefore to be chosen. One is readily obtained with a small point that will drop half-minims, or even less. The use of such a dropper allows the employment of stronger solutions than it would otherwise be safe to employ, or a large number of instillations may be made in the same space of time without producing symptoms of mydriatic poisoning.

It is by attention to such a minute point of technique that one surgeon will at once secure the dilatation of an inflamed iris, or the complete relaxation of the accommodation under homatropine, where another less careful will fail to attain the end sought, or to give relief to his patient. And even where the utmost power of the mydriatic does not need to be exerted, to obtain the effect that is required with the least danger of constitutional symptoms, or with the minimum of constitutional disturbance, is a very important point; for these symptoms, although really not indicating any danger to life, are extremely annoying and alarming to the patient. They occur quite frequently after the use of mydriatic solutions, and such occurrence has much to do with the objection of patients to the use of mydriatics in the diagnosis of ametropia.

The strength of the solution of one of these drugs to be used in the eye varies with the purpose for which it is used. To break up the adhesions in a case of iritis, the stronger mydriatics are to be employed and in strong solution; as atropine sulphate 1 to water 50, or about 10 grains to the fluidounce; daturine sulphate 1 to water 100, or about 5 grains to the fluidounce; duboisine sulphate 1 to water 100, or about 5 grains to the fluidounce; hyoscyamine sulphate or hydrobromate 1 to water 100, or about 5 grains to the fluidounce. The effect of either of these solutions may be somewhat increased by using cocaine with it. But the patient should not be intrusted with the cocaine solution for home use, because the temporary comfort it gives, in many cases, leads sometimes to dangerous excess. Either of the above solutions is to be used one small drop in the eye at a time at intervals of ten minutes until the dilatation of the pupil is secured, and then at such intervals as may be necessary to maintain such dilatation; and continued three times daily until it can be replaced by a weaker solution.

In making the mydriatic attack on a case of plastic irritis, it is, to a certain extent, simply a question of whether we can get enough of the mydriatic into the eye without getting too much into the general circulation. And to accomplish this we must prevent the solution from making its way into the tear passages, and so being absorbed from the respiratory and digestive tracts, as well as from the conjunctiva. For this purpose it is often recommended to make pressure on the inner canthus. But such pressure is quite ineffective. Even the placing of a little clamp on each canaliculus, as proposed by Dr. Tansley (*Trans. Amer. Opthalmological Society*, 1888,) does good mainly by the displacement of the puncta that it causes. The most effective means is to so draw on the skin of the lids as to evert the puncta, and hold in contact with them a small pledget of dry absorbent cotton. This will prevent the passage of any fluid from the eye into the lachrymal sac, and permit us to apply the mydriatic vigorously to the cornea.

For paralyzing the accommodation of the eye, solutions of the same drugs of about half the above-mentioned strengths may be instilled three or four times daily.

Probably a single efficient instillation of this kind, or at most two or three would be sufficient to produce complete paralysis of the accommodation in almost every case, with the eye in anything like normal condition. But frequently the instillation must be intrusted to unskilled hands, and so may produce but a small fraction of its full effect, and in a few cases the active hyperæmia, caused by the mydriatic and involving the anterior segment of the globe, may increase the difficulty of attaining complete ciliary paralysis; so that it may be necessary to continue such applications for some days.

For simply paralyzing the accommodation, however, our most valuable agent is homatropine, commonly used in the form of the hydrobromate. Of this a two or three per cent. solution, ten or fifteen grains to the fluidounce, should be instilled every five or ten minutes until at least four efficient applications have been made. Used in this way, I have found it a perfectly reliable and efficient paralyzant of the accommodation, even in the presence of high grades of retinochoroidal irritation and general hyperæmia of the eye. But we have not with this drug the excess, or reserve of power to control the ciliary muscle, that is possessed by the other

mydriatics named. Every instillation or at least a sufficient number of them must be efficient. The cornea must have the chance of absorbing the solution at nearly its full strength; and for that reason the application of the drug must be intrusted only to skilled hands, usually attended to by the surgeon himself.

To bring about simple dilatation of the pupil our choice of the drug will be determined by whether the dilatation is to be long sustained as a measure of treatment, or only temporary as for purposes of diagnosis. In the former case atropine is to be used, in the latter, homatropine or cocaine. Atropine or homatropine should be employed in a solution one-tenth the strength of those used for paralyzing the accommodation, or even weaker than this. The atropine to be repeated as often as the pupil contracts again, say once every one, two or three days; the others, of course, used only the once.

Cocaine, which is of especial value as a dilator of the pupil, is to be used in solutions of the ordinary strength ordinarily employed for producing local anæsthesia of the eye, that is, two to four per cent. But the instillation must be made at least thirty minutes often an hour, before the dilatation is desired, the anæsthetic action often having quite passed away before the dilatation of the pupil becomes noticeable, and repeated instillations do not very greatly hasten this dilatation. As a paralyzant of accommodation cocaine has very little power, and by itself is not at all valuable for the purpose. But it can sometimes be advantageously combined with homatropine. Here the frequent repetitions of the instillation, as in the case of iritis, give the advantage of local anæsthesia, greatly lessened resistance on the part of some patients, and prevention of the excessive secretion of tears that follows each instillation of homatropine alone and by dilution of the solution lessens the intra-ocular effects produced, as well as an apparent hastening of absorption. For this purpose the solution may be made with two or three per cent. each, of cocaine and homatropine.

The instillation of a strong solution of any of the mydriatics causes a pericorneal hyperæmia, which, though not serious, is sometimes alarming to the patient or his friends. This phenomena I pointed out in a paper on homatropine, published in *The Medical News*, July 18th. It is especially liable to occur from the use of homatropine, because this is more likely to be used in stronger solutions. The combination with cocaine lessens this tendency to a considerable extent.

Selected Formulæ.

FŒTID BREATH.

This may arise from decaying teeth, or it may come from some stomach difficulty, as impaired digestion; lung troubles may cause it. In any event, thorough cleansing of the teeth and a camphorated dentifrice is by many thought more useful than other varieties. The following formulæs are commended by various authors as to the several sources of the trouble. The active materials for disinfecting being one of the following articles: Carbolic acid, chlorine water, potassium permanganate, thymol, salicylic acid, camphor, borax.

1. Camphor water; water, equal parts; use as a mouth wash.

2. Thymol, 10 grains; alcohol, 1 ounce; borax, 30 grains; water 19 ounces.

3. Potassium permanganate, 8 grains; water, 8 ounces.

4. Chlorine water, 1 ounce; glycerin, 2 fluid ounces; water, 14 ounces.

5. Salicylic acid, 120 grains; glycerin, 2 fluid ounces; water, 6 ounces.

6. Borax, 240 grains; water, 1 pint.

7. Chlorinated lime, 120 grains; sodium carbonate, 160 grains; water, 6 ounces; alcohol, 2 ounces; rose water, 12 ounces. Dissolve the sodium carbonate in 2 ounces of the water, rub the chlorinated lime to a paste with water, adding in all 4 ounces; mix in a 12-ounce bottle, adding the alcohol. After the reaction separate the clear solution and add to the rose water.

8. Salicylic acid, sodium bicarbonate, saccharine, each 60 grains; alcohol, water, each 4 fluid ounces; oils of peppermint, 5 drops. Of this solution, use two teaspoonfuls to a wineglass of hot water, and use as a gargle twice daily.—*Pharm. Rec.*

TREATMENT OF URTICARIA.

Quinquaud (*La Tribune Médicale*) recommends in cases of intermittent urticaria, quinia, but preferably arsenic. In the chronic form, baths and hydrotherapy in all its forms are to be absolutely forbidden. On the other hand, wrapping the patient up in cotton batting is often excellent. Internally alkalies, arseniate of soda, naphthol, are indicated.

For the pruritus he advises:

℞

Aq. lauro-cerasi	grammes	50.
Chloral	"	5.
Aquæ	"	200.

M.

Or,

℞ Ether.....grammes 30.
Tepid water..... " 60.
M.

Also a powder for dusting on the surface:

℞ Amyli.....grammes 50.
Zinci oxid..... " 10.
Or
Acid. salicyl..... " 5.
M.

When fresh outbreaks supervene, one-fourth of a milligramme of aconitine in divided doses will prove serviceable.

PERMANGANATE OF POTASSIUM IN DIPHTHERIA.

Dr. Netzetzky says that his twenty-two years' practice convinced him that the best treatment of faucial diphtheria consists in an energetic use of permanganate of potassium. The drug should be administered in the shape of paintings and gargle. The following strong solution should be employed:

℞ Potassii permanganatis.....3 j.
Aquæ destillatæ.....3 j.
M. Sig. To paint the affected surface every three hours.

For gargling, which is to be repeated as often, a teaspoonful of the same solution should be mixed with a tumblerful of boiled water.

In those cases in which the child is unable to gargle, the following mixture should be given internally:

℞ Solutionis hydrogenis superoxydati, two per cent.....3 ij.
Glycerinæ.....3 ij.
M. Sig. A teaspoonful every two hours.

TREATMENT OF SYCOSIS.

Rosenthal in the *Annales de Dermatol. and de Syphilog*, recommends the following method, which possesses the advantages of facility of application, freedom from pain, and relatively rapid cure.

The diseased surfaces should be carefully shaven each day and the following ointment applied two or three times a day:

℞ Tannic acid.....grammes 1
Sulphur..... " 2
Vaselin..... " 10
M.

After the friction with this ointment at night, an emollient ointment, Wilson's or Hebra's, may be applied.

The writer has also recently employed with good results the following paste:

℞ Tannic acid.....grammes 5.
Sulphur..... " 10.
Oxide of zinc.
Starch., aa..... c.cm. 17-50.
Vaselin..... c.cm. 50.
M.

This may be applied night and morning. By this method epilation may be dispensed with.

HAY ASTHMA.

℞ Cocainæ hydrochlor.....3jss.
Glycerini.....f 3iij.
Aquæ destil.....f 3v.
M. Sig. At the onset of the attack make two applications, with an interval of five minutes, by means of a brush, to the accessible nasal mucus membrane.

℞ Cocainæ hydrochlor.....3ss.
Benzoini, pulv.....3jss.
Sacchari, pulv.....3ss.
M. Sig. Use as a snuff.

—*L' Union Méd.*, April 18, 1891.

CHLOROSIS.

Liégeois (*Lyon Medical*, in *Boston Med. and Surg. Journal*) has obtained very satisfactory results from the following formulæ, suggested by Luton:

℞ Cupri acetatis neut.....gr. ⅙.
Sodii phosphat., cryst.....gr. ¾.
Pulv. glycyrrhizæ
Glycerinæ., aa.....q. s. M.
Ft. pil. j.

One or two pills before eating, noon and night.

CHOLAGOGUE TABLETS.

℞ Sodii benzoatis
Sodii salicylatis } aa.....3j.
Rhei pulv.
Ext. nucis vomicæ.....gr. v.
M. Ft. tabellæ no. xx.
Sig. One at each meal.

—HUCHARD, *La Méd. Mod.*, May 7, 1891.

INFANT FEEDING.

Dr. Toussains states that he has prevented derangement of the alimentary canal of infants during hot weather by giving after each meal a teaspoonful of the following mixture:

℞ Papaini..... gramme 0.5.
Acid lactici.....grammes 2.0.
Aqu. dest..... " 150.0.
Syrup simpl..... " 50.0.
Tr. vanilli, q. s.
M.

Besides, he gives as nourishment, equal parts of milk and Vichy water, together with malt flour, in teaspoonful doses, diluted with four times the quantity of hot water.

In some cases the milk was omitted, and malt flour alone was given as a nourishment, and white of egg, water, with a little rum and sugar, as a drink.

In many cases the beneficial effect of malt flour (*Farine maltes de Dupresne*) was noted.
—*Cent. f. g. Ther.*

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

EDWARD T. REICHERT, M. D.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF PENNA.,
EDITOR AND MANAGER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

THE MEDICAL AND SURGICAL REPORTER.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent 3 months on trial for $1.

At the termination of the period of subscription, we will promptly discontinue sending THE REPORTER unless directed to the contrary by the subscriber.

Remittances should be made by draft, check, postal note, or money order payable to Edward T. Reichert.

THE POCKET RECORD AND VISITING LIST.

Two sizes. Prices to subscribers of THE REPORTER: For 30 patients a week (with or without dates), $1.00. For 60 patients a week (without dates), . . $1.25. Prices to non-subscribers, $1.25 and $1.50 respectively.

THE MODEL LEDGER.

Physicians who keep their own books will find this of great value. Sample pages sent on application. Price, $5.00.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If THE REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS.

Write in ink.

Write on one side of paper only.

Write on foolscap or legalcap paper.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be pleased to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

LEADING ARTICLE.

THE ACTIONS OF OPIUM AND MORPHINE IN THE INTESTINES.

In spite of the extended use of opium and its alkaloids in diseases of the intestinal tract, we have been, up to the present, very largely ignorant of the exact therapeutic action of these drugs, and the knowledge which we have experimentally gained has been but fragmentary. Neither has it been conclusively shown why opium, in these diseases, has been empirically given the preference to morphine, the latter drug being so easy of administration and always readily obtained in absolute purity.

To satisfactorily answer these interesting questions has been the effort of Dr. Wilhelm Spitzer, and the article in which he gives the results of his experiments was given the prize of the University of Breslau this year, and has subsequently been published in *Virchow's Archives*, Vol. 123, No. 3, 1891.

The article opens with a historical review of the experimental researches of the actions of opiates, on the intestines of both cold and warm blooded animals, in order to prove whether opiates do not exert, apart from the cerebro-spinal action, a local or regionary action, by resorption. Further, the comparative study of the gastro-intestinal actions of opium and morphine, and also whether, as has been generally empirically accepted, the first-named drug is not weaker in its anti-diarrhœic and anodyne properties than the latter. The review shows, however, that the works of previous writers do not satisfactorily or conclusively answer these questions.

While this portion of Dr. Spitzer's work is of great interest, we will turn aside from it and briefly consider the results of his experiments upon the human organism. Of these very many were upon healthy subjects. During certain fixed periods, opium and morphine were given by the stomach, and hypodermically, and their constipating actions carefully noted. The cases were carefully

chosen from among inmates of the Almshouse and convalescents from Hospitals. All were equally well nourished and received about the same amount of exercise, etc. Naturally, only such subjects were chosen who did not habitually use any opiates, and whose bowels were habitually regular, all being in the habit of defæcating at certain fixed hours of the day. It was clearly proven by these experiments that opium given subcutaneously did not exert any greater constipating action than the morphine represented in the dose would have done.

The following is a brief resumé of the principal experiments.

First.—In the majority of subjects, defæcation took place in the morning, and in order to retard this action for twenty-four hours, on an average 0.01 gramme, or at the most 0.02 gramme of morphine given subcutaneously, was required. Twenty-six experiments upon sixteen different subjects, with hypodermic injections of morphine, resulted as follows: Three experiments with 0.004 gramme, and two experiments with 0.006 gramme resulted negatively. In ten experiments 0.01 gramme was injected, and of these five resulted negatively and five positively. In the latter, the delayment of defæcation was six hours in one case, twenty-four hours in three cases, and thirty hours in one case. With the hypodermic dose of 0.015 gramme, eight experiments were made, and in five instances constipation was induced, lasting eighteen hours in one case, and twenty-four hours in three cases. In three cases, finally, a delayment of defæcation, lasting for twenty-four hours, could only be produced by doses of 0.02 gramme. In the majority of the experiments of this series, the author began with small doses, and gradually increased them until the desired effect was obtained.

Second.—The aqueous extract of opium was used hyperdomically in twenty-three experiments upon fifteen different subjects. In order to delay the time of habitual defæcation for twenty-four hours on an average, 0.1 to 0.15 gramme was necessary. The lowest quantity injected was 0.025 gramme in one case, and the result was negative. 0.03 gramme was used eight times; once it occasioned a delaying of defæcation for eighteen hours, but in the other cases it had no effect. Doses ranging from 0.04 to 0.08 gramme were tried in several cases, but had no constipating effect. Injections of 0.1 gramme caused a constipation lasting for twenty-four hours in two cases, but in two other cases it was without result. 0.15 gramme was tried in two cases, causing constipation for thirty-six hours.

The above experiments demonstrate that the aqueous extract of opium, given hypodermically, does not constipate unless given in doses of 0.1 to 0.15 gramme, and that then the action is the same as would be achieved by the morphine the drug contains, viz: 0.01 to 0.015 gramme, or ten per cent. There is, therefore, no advantage in using the extract of opium hypodermically in place of morphine. Quite the contrary, indeed, for the author noted that frequently where 0.05 gramme of the extract of opium had been injected, and in two cases only 0.03 gramme, unpleasant accompanying effects were induced, such as dizziness, headache and excitability; while in equally as constipating doses of morphine no accompanying symptoms other than sleepiness, and rarely vomiting, were noted. According to Spitzer, therefore, it is a mistake to use opium hypodermically in place of morphine when a constipating action is desired.

Third.—Regarding the exhibition of opium per os, either in the form of the simple tincture, the aqueous extract, or pure opium, it was found that the constipating dose was somewhat smaller than that required in hypodermic injections of the drug. Often 0.06 gramme produced the desired result. It was also shown that both the extract and pure opium, were more active than the tincture.

Fourth.—Upon a large number of subjects who had previously been tested in the experiments on the constipating action of opium given internally, the comparative value of morphine given hypodermically was tried, and a comparison of the results of these with the experiments of the third and first series showed that opium given internally in any

form produced constipation somewhat more easily than morphine given either hypodermically or per os. The experiments further showed that the accompanying symptoms produced by morphine, given either by subcutaneous injection or by mouth, were far more severe than those caused by opium when given by the mouth. The author, therefore, claims that in practice, the exhibition of opium per os should always be preferred to the administration of morphine when a constipating action is desired.

Regarding pathologically quickened peristalsis, the ætiology of the various forms of diarrhœa alone showed that an easily induced anti-diarrhœic action results from the use of morphine, but the difference in intensity is slight. In all cases the aqueous extracts of opium acted the best. It was given in a mucilagious vehicle (gum arabic) and in small doses, of about 0.02 gramme six times a day. In a few cases the extract was of decided greater efficiency than the other preparations.

In the treatment of diarrhœa, morphine was given in sixteen instances to ten different patients—eight times internally and eight times hypodermically. To obtain the desired action, in three cases 0.01 gramme of morphine per os was found necessary, in four other cases 0.015 gramme, and in one case 0.03 gramme. When given hypodermically similar results were obtained by 0.01 gramme in two cases, 0.015 gramme in one case, 0.02 gramme in three and 0.025 and 0.03 in one case each. In these as well as the following experiments the treatment was always commenced with small doses, which were gradually increased until intestinal rest was obtained.

The aqueous extract was given internally in six cases, and subcutaneously in eight cases. In the former instance the required dose ranged from 0.04 to 015 gramme. Subcutaneously, a similar action was obtainable with 0.075 gramme and 0.01 gramme in two cases each, 0.15 in one case, and 0.2 gramme in three cases.

The simple tincture of opium was given in twelve cases. In five of these 0.5 gramme was sufficient to check the diarrhœa, in four 0.75 gramme, in one 1.0 gramme, and in two 2.0 gramme accomplished like results.

Pure opium, which, of course, was only given internally, exerted an action similar to that of the aqueous extract, when given similarly.

From these experiments it will be seen that in cases of diarrhœa, opium only when given per os, acts somewhat better than morphine, but that otherwise their actions are equal.

As an intestinal anodyne when given internally opium acts somewhat more rapidly than morphine per os. When, however, the pain is intense, and a rapid therapeutic action is desired, subcutaneous injections of morphine of 0.01 to 0.015 gramme were found to be the most efficient remedy.

Spitzer's experiments with other alkaloids of opium, including codeine, papaverine, narcotine and narceine, resulted negatively, at least in doses which were free from unpleasant accompanying effects.

In opium and morphine we have one of our main bulwarks of therapeutics, and anything throwing light upon their exact therapeutic value and use, cannot fail but be of more than ordinary interest and practical service to the busy practitioner, and the profession is certainly indebted to Dr. Spitzer for some exceedingly valuable data.

Correspondence.

A SINGULAR CASE.

The following letter setting forth a very exceptional case of long suffering from pulmonary trouble, we publish at the request of the sufferer, who has the hope that some good to science and humanity may result from the publication:

Dear Sir:—I have good reason to believe I am a sufferer from one of the most peculiar forms of pulmonic troubles with which any mortal has ever been afflicted, and while I have no desire to obtrude myself or my troubles upon the public, I have concluded to make the facts of my case known, in the hope that they may attract the attention of some medical expert who may be able to tell the source of my afflic-

tion, or may learn from my case something that may be a benefit to other sufferers.

I was born in 1834, and two years after I was attacked by what the physicians attending me pronounced palpitation of the heart. This illness left me with a serious form of lung trouble, from which I have suffered ever since, and to me it is a most astonishing fact that I have lived to be heard of, and it is a mystery which no physician I have met with has been able to fathom. I have coughed almost constantly and have raised at least one pound of mucus matter per day for fifty-four years, an aggregate of nearly ten tons, from my lungs. Some will doubtless say they do not believe this, but I am prepared to prove it.

I have suffered all my life from trouble and have lain in bed for weeks and months at a time. Twice in my life I was so low and emaciated that my back bone and my elbows came through my skin; but through all God has spared my life—I hope for some good purpose.

My condition and the trouble I have passed through has been a source of astonishment to all the physicians I have met; but I have never yet met any two who agree with regard to my trouble. They all have had different theories about it. I never expect to recover, but I have always thought that I may meet with some medical expert who, by examining me, may be able to locate my trouble and tell me the cause of it.

To have such knowledge would render me very happy indeed, and to obtain it I am willing to go to any part of the United States to be examined free of charge. Besides, I believe that the knowledge to be obtained from my case would be of much advantage to medical science.

Except in extreme cases, I have always doctored myself with herbs, and I believe the reason that I have been able to fight this cough and trouble off so long is that my nervous system never gave out.

SAMUEL GORDON,
South River, N. J.

INVAGINATION OF THE BOWEL.

ED. MEDICAL AND SURGICAL REPORTER.—

The 1st of July G. I. T.—, a man of 70 years, of this place, had a few fæcal motions; the last attempt was bloody mucus. Pain continued in the bowels, with occasional vomiting, which on the 5th was stercoracious. All attempts to move his bowels, which were supposed to be loaded, having failed, large enemas were attempted to reduce the difficulty. The morning of the 6th I saw him with one of his three physicians, but found no paralysis of the bowels, which had been diagnosed as his trouble. The abdomen was soft and tender from flatulence, but eased by continued pressure.

After a long enema, it was ejected simply discolored. An active cathartic was prescribed, in hope of dislodging the invagination.

℞

Chlor hydrarg. mit.....gr. ij.
Ex. hyoscyan.....gr. jss.
Podophyllini.....gr. ⅛.
M. et div. in pil. nos. v.
Sig. One pill to be taken every two hours until relieved.

Egg-nogg to a half-pint with 2 oz. of whiskey, was given every four hours. He took five pills and before the time for the sixth, they began to act. Five motions followed.

On the morning of the 7th he was relieved from all distress, craved beef-steak. On the 8th he was improving, and on the 9th rode out. On the 10th was in a wheat field directing the work. Respectfully,

EDWARD VANDERPOEL,
New Suffolk, N. Y.

BOOK REVIEWS.

MANUAL OF THE DOMESTIC HYGIENE OF THE CHILD. FOR THE USE OF STUDENTS, PHYSICIANS, SANITARY OFFICIALS, TEACHERS AND MOTHERS. By JULIUS UFFELMANN, M. D. Edited by Mary Putnam Jacobi, M. D. E. P. Putnam's Sons: New York and London, 1891.

This is a work that bids fair to become classical at once; for while it is thoroughly scientific in every detail, and thorough even to minuteness, it is written in such a way that any mother of fair intelligence will have but little difficulty in understanding it and absorbing its truths.

The author rightly realizes that "the entire constitution of the adult—his power of resistance, his capacity for work—depends first of all upon his childhood, and upon the care he may have received during the formative period of his existence;" and while most writers on this subject are content to treat only of the earlier years of life, Prof. Uffelmann has given just as faithful study to the period preceding adolescence as to that of infancy and childhood. The question of the nature and preparation of the various foods for children is thoroughly discussed, valuable advice is given as to the care of the body in general and of its different organs or

systems, and the anthropometrical tables furnished a standard by which the growth and development of the child can be rightly judged. Thanks to the additions of Dr. Jacobi—which have been included in the text in brackets,—the work is made additionally clear for the laity, and that class of educated and intelligent women who wish to know as much as possible about the proper care and supervision of their children's development will, as well as the physician, find this book most worthy to be added to their libraries and to be studied and restudied many times.

PERISCOPE.

THERAPEUTICS.

THERAPEUTICAL USES OF MENTHOL.

The drug has an undoubted sedative action upon the mucous membrane of the stomach, and often gives relief in gastralgia, nervous dyspepsia, and some forms of acute indigestion.

I often employ this formula with success:

℞ Mentholis..... grs. v—viii.
Elix. lactopep... ..... ʒ i.
M. Sig. To be taken in hot water every hour until relieved.

In cases of obstinate vomiting, the same dose dissolved in lacto-peptine or brandy will often afford relief.

In some forms of neuralgic or irritative headache, as well as those for which we are wont to prescribe the coal-tar products, menthol, in 10-grain doses in hot whiskey is sometimes very effective.

In most varieties of pruritus, whether general or local, the following lotion is quite reliable:

℞ Mentholis..... ʒ i.
Spts. vin. rect..... ʒ i.
Aquæ..... ʒ ij.
M. et adde.....
Acid. acetic. dil..... ʒ v.
M. Sig. Apply with sponge as required.

In localized skin diseases where an antipruritic ointment is needed, the following is a good combination:

℞ Campho-phenique..... ʒ i.
Mentholis..... grs. xxx.
Ung. aq. rosæ..... ʒ i.
M.

In all cases where the skin is broken or denuded, campho-phenique gives better results than menthol. The latter may be combined equally well with zinc, balsam of Peru, or tar for these purposes.

Mentholated cologne forms a very comfortable and effective evaporating lotion in congestive headaches and similar conditions. It forms also a valuable ingredient of liniments of various kinds, to which it may be added in the proportion of thirty grains to the ounce.

All are doubtless familiar with its anæsthetic effect when used in the form of a spray in combination with ether and chloroform.

The action of the agent upon various affections of the respiratory organs is also well marked. Here the menstrum or solvent should be some of the bland oils like petroleum, or, what I have found still better, albolene or glymol. A solution of twenty or thirty grains of menthol to an ounce of glymol, applied to the nasal passages by a proper atomizer, is the best thing I have yet used for colds in the head where there is almost complete occlusion from congestion of the mucous membrane. In the more chronic catarrhs of the naso-pharynx, the results are sometimes equally good.

A similar solution often affords relief in cases of acute or chronic laryngitis and laryngeal cough, and phthisical patients remark forcibly upon the relief afforded by it in these conditions. To the solution of creosote, chloroform, and alcohol commonly employed in the Robinson and similar inhalers, menthol in 20-per-cent. strength may be added with good effect.

Certain forms of sore and irritable throat are greatly benefited by a gargle composed of an alcoholic solution of this drug.

The uses of menthol are almost infinite, and being readily soluble in alcohol, ether, and the various oils, can be administered in many different forms.

It is a decided anæsthetic, an alterative, an antiphlogistic, and an antiseptic.—Dr. J. J. Berry in the *Med. Mirror.*

THE TREATMENT OF HYDROCEPHALUS.

Ouiniche, of Kiel, has made some interesting observations upon the treatment of acute and chronic hydrocephalus by paracentesis. The symptoms of cerebral compression are the indications for active treatment. In operating, the author makes the punctures through the cranial bones, sometimes with a very fine drill, or sometimes he has used a trephine to make an opening through the osseous tissue. He has also punctured the spinal canal in the lumbar region. The lumbar puncture is made by means of a grooved needle introduced through the skin, and between the vertebral arches into the sub-aractenoid cavity, without injuring the

roots of the nerves or the spinal cord. The author relates some cases in which the pressure signs were much relieved by the lumbar puncture. In acute and chronic hydrocephalus, as well as in tubercular meningitis where signs of pressure are present, the withdrawal of serous fluid from the aractenoid sac is attended with much relief.—*Med. Press.*

TREATMENT OF OXALURIA BY PERMANGANATE OF POTASH.

Dr. H. J. Norris, writes in the *Mass. Med. Jour.:* When the deposit of oxalate of lime occurs, as it frequently does, associated with free uric acid and the urates, we are apparently involved in a contradiction as regards treatment. While the one, the uric acid deposit, is often treated with advantage by alkalies, the other requires the mineral acids. We adopt the view of Dr. Prout, that, "the oxalate of lime diathesis, and the uric acid diathesis, are of the same general nature; and being of a similar nature, the principles of treatment adopted for counteracting the original tendency to it, must be also similar." There cannot be any question but that urea, uric acid, and oxalic acid are much the same thing though at a different stage of formation; for one is easily converted into the other, out of the body by very simple chemical means; and there is reason to believe that, in the organism they are the products of physiological waste of the same tissue. We do not hesitate, therefore, to affirm that the uric acid and oxalate occur as the result of a deficient oxidation.

When we consider the fact, that uric acid may disappear entirely from the urine, and that oxalic acid is not normally present, is it not fair to conclude that the uric acid must, in the normal condition of things, undergo decomposition in the body? We find that by adding an excess of permanganate of potassa to uric acid out of the body, it is directly converted into urea and carbonic acid; and that when the oxidation is less complete, it passes into the form of urea, oxalic acid, and carbonic acid. If, therefore, we would prevent the formation of uric acid and oxalic acid, we must supply the equivalents of oxygen and of water. This is most conveniently done in the form of permanganate of potassa:

℞ Permanganate of Potassa..... grs. viij.
Water..... f℥ij.
M. Sig.—One teaspoonful to be given three times a day.

It should not be given except on an empty stomach; for in contact with organic matter it is decomposed, yielding its oxygen to any element, simple or compound, that will receive it. Dr. Norris has repeatedly directed, during the past four years, the permanganate to be given as above, in oxaluria, with the most happy results.

PILOCARPIN IN ŒDEMA OF THE GLOTTIS.

At a recent meeting (May 4th–5th) of the French Society of Otology and Laryngology, Dr. Suarez de Mendoza, of Angers, related (*Semaine Médicale*, May 6th, 1891) a case in which he was called in to see a young man attacked by serious œdema of the glottis causing suffocative dyspnœa. Tracheotomy had been proposed, but Suarez de Mendoza, seeing that in the middle of the swelling a narrow slit was still visible during inspiratory effort, suggested that pilocarpin, which he had already found successful in two similar cases, should be tried. Three hypodermic injections were given at intervals of twenty minutes, the total amount of pilocarpin administered being 25 milligrammes. Marked relief followed the first injection, and a quarter of an hour after the third the patient was breathing easily and quietly, and was entirely out of danger. In eight days he was quite well.—*Brit. Med. Jour.*

PHYSIOLOGICAL EFFECT OF BATHS IN TYPHOID FEVER.

Dr. Kurkutoff, who has examined the physiological effects of baths administered to typhoid fever patients in Professor Manassein's clinic in St. Petersburg, finds that such baths exert only a slight effect on the assimilation of the fatty constituents of foods, which, as in other fevers, is notably less than in healthy persons, and indeed varies directly with the gravity of the case; but there seems to be a good deal of difference as to the power of assimilation of fatty matter in different cases, probably depending on the functional disturbance in the bowel and on the amount of the individual peculiarities of the patient. In the graver cases the effect of the baths was to improve somewhat the assimilation of fat to the average extent of nearly four per cent. In slight cases, however, the effect was, apparently at least, to diminish the assimilation to the average extent of rather more than six per cent.—*Lancet.*

TREATMENT OF THE "RED NOSE."

A red nose is a very painful affection, especially when it attacks females. Accord-

ing to Unna, one-fifth of the cases are due to acne rocacea with vascular dilatation. Very often it stands in direct relation to seborrhea of the hairy skin. This seborrhea should be treated in the usual way. When acne rosacea is the cause, Unna gives fifty centigrams (seven and a half grains) of ichthyol daily internally, and at the same time prescribes lotions of the same substance in watery solution externally. At night, applications of the following paste are of benefit:

℞

Zinc pomade	20.0
Rice powder	5.0
Sulphur	2.0

Unna advises multiple scarifications of the dilated veins after Hebra. This should be repeated two or three times a week. The minute wounds should be covered at once with moist absorbent cotton. In light cases, and as supplementary treatment, he advises repeated washings with ichthyol soap. Only warm water should be used.—*Amer. Pract. and News*, May, 1891.

THE TREATMENT OF SPRAINS.

Dr. Duhamel recommends warmly the use of a plaster composed of one part of carbonate of lead in two parts of olive oil as an application to sprained joints. He heard of this remedy when on a visit in Holland, and on his return to France immediately put it to trial in a number of cases. Most of the cases were sprains of the ankle, and the patients were made to walk as soon as the plaster and retaining dressings had been applied. All these cases made a rapid recovery, but one case of a sprain of the wrist, in which the same remedy was applied, did not improve. The cure was obtained in all probability by the exercise of the joint rather than by any especial virtue residing in the white lead.

HYPNOTISM.

Dr. Cruise related, at some length, what he had seen at Nancy, under Drs. Liébault and Bernheim, and his experiences of the clinical instruction on hypnotism by M. Luys at the Charité Hospital in Paris, and of M. Auguste Voisin and M. Guinon, at the Salpêtriere. He discussed the utility of hypnotism, pointing out the cases best suited for it, recounting his own experiences, and replying to the objections, physical and moral, which had been urged against it. He concluded by urging all to study the subject practically before committing themselves to an adverse opinion.—Dr. G. C. Kingsbury pointed out that when Charcot spoke of hypnotism he referred to certain manifestations of disease met with rarely amongst hystero-epileptics, whereas what was meant by hypnotism at Nancy was not a disease but a method of treatment. That this method of treatment was based on common sense was shown by reference to the every-day experience of physicians of the effect of the mind or imagination on the body, and quotations in support of this were given from Stokes, Graves, Paget, and Trousseau. Hypnotism sought by exalting this power to heighten its effect. It was shown that the principle underlying all the methods was the continued stimulation of one or more of the senses, with the constant suggestion of sleep. The further process of treatment was then detailed, and it was shown how the verbal suggestion of relief, of which it mainly consisted, could be greatly emphasized, according to the nature of the case; for example, by friction in rheumatism or neuralgia, by inducing the patient to inspire deeply in pleuritic affections, by ordering the patient to walk in functional paralysis, etc. The process of dehypnotism, or waking, was also explained. The opinion that the subjects of hypnosis were greatly fatigued after the process was erroneous. Any medical man who would take the trouble to study the subject could hypnotise, but here, as elsewhere, individual qualities would tell, some men always being more successful than others. "Who can be hypnotised?" was then considered, and it was shown that as distinctly the majority of people were susceptible, it was more important to know who could not be hypnotised; but Dr. Kingsbury believed he was within the mark in saying that 70 per cent. were hypnotisable, though only 15 per cent. would be found to be somnambulists. Children between 7 and 14 years of age were found to be the best subjects, 50 per cent. being somnambulists. Hysterical people were very difficult subjects. Lunatics were about the worst subjects, while imbeciles were practically impossible. Phthisical patients were particularly susceptible. Sex did not exert any marked influence. Nationality did not seem to be an important factor either, though the Oriental races were held to be the most easily influenced. Ill-health was by no means an essential, some of the best subjects being athletes. Dr. Kingsbury held it to be justifiable to try hypnotism in all cases where a distinctly nervous element could be detected. All functional disorders might also be treated by means of hypnotic

suggestion. Hypnotism might be used in conjunction with drugs, whilst in some cases it might be tried alone. In midwifery, hypnotism seemed justifiable wherever any anæsthetic was thought necessary. It might be employed in many cases of ovarian pain and menstrual derangement. The alienist was justified in trying hypnotism, Voisin having succeeded with 10 per cent. of his patients, and Forel, of Zürich, having hypnotised 14 out of the first 33 patients tried. Moral ailments seemed to offer a wide field for the trial of hypnotism, and included cases of inebriety, morphinomania, cocainomania, kleptomania, masturbation, etc. In surgical cases Dr. Kingsbury declared that if he knew that a patient could be hypnotised deeply, so as to be completely anæsthetised, he would prefer to employ hypnotism rather than chloroform for operative purposes. The dangers of hypnotism were grossly exaggerated. He had failed to find any case where insanity could be shown to have been produced by hypnotism employed by a medical man. It was time that the practice of hypnotism should be confined to the medical profession by right, but he maintained that scientists should be allowed to conduct hypnotic experiments for the elucidation of physiological and psychical problems. All that he asked for was a careful and scientific testing of hypnotism.—Dr. Foot wished to hear a differential diagnosis between mesmerism and hypnotism, because many great men had made shipwreck of their reputations on the rock of mesmerism. He thought that non-organic functional disease was the feeding ground for every form of quackery. He was anxious to hear how long the cures of dipsomania had lasted.—Dr. Joseph Redmond mentioned the case of a girl, aged 19, who had suffered severe pain in the side for five years. All sorts of treatment had been tried in vain. Dr. Cruise hypnotised her five or six times, and completely cured her of the pain.—Dr. M'Cullagh mentioned two cases in which he had performed circumcision painlessly under hypnotism.—Dr. J. J. Murphy related cases of dipsomania, masturbation, etc., in which hypnotism had done good.—Mr. Edward Hamilton, when a young practitioner, remembered a case of fever in which all narcotics failed. He sat by the patient's bedside, and, fixing his eyes on him, wished intensely, almost prayed, that he might sleep. After a few minutes the patient's eyes drooped, and he slept for some hours, which caused him the greatest benefit.—Dr. Connolly Norman said the evils of hypnotism had undoubtedly been absurdly exaggerated, nevertheless there were dangers. In a case of his own he believed general paralysis had originated in the constant practice of hypnotism. There could be no doubt of the service which hypnotism could render, at least for a time, in dipsomania; and in true insanity good might occasionally be done, and many patients were quite susceptible.—Dr. Fitzgerald mentioned two cases in which he obtained great benefit from hypnotism.—Dr. Richard Hayes related two typical cases in which hypnotic suggestion had succeeded in relieving symptoms.—Mr. Wheeler asked what difference there was between hypnotism and electro-biology.—Dr. Cox and Dr. O'Carrol also spoke.—In answer to Dr. Foot, Dr. Kingsbury explained that practically there was no difference between mesmerism and hypnotism. Those who were familiar with hypnotism did not limit its employment to the field of "non-organic functional disorders," but found it useful alone or in conjunction with other remedies in surgery, in midwifery, and in the treatment of many ailments outside the pale indicated by Dr. Foot, such as rheumatism, neuralgia, pneumonia, tinnitus. Dr. Foot had scoffed at the idea of inebriety being cured by hypnotic suggestion, and thought these cures were only the temporary repentances of drunkards recovering from a debauch, such as they all frequently witnessed. If Dr. Foot would read what had been written, he would find well-authenticated cases of inebriates keeping sober for ten or twenty years, which periods certainly exceeded the length of alcoholic remorse. Dr. Norman thought Dr. Voisin deserved in a measure the reception he got at Leeds, on account of his wild extravagance. Perhaps Dr. Voisin did portray the rosy side of hypnotism, but one of the statements made by him, which was at the time considered most incredible, was that the menstrual functions or the action of the bowels could in any way be controlled by means of suggestion. Both these statements had been amply corroborated since. Mr. Wheeler wished to know what relation hypnotism had to electro-biology. It was one and the same thing.—*Brit. Med. Jour.*

MEDICINE.

THE TETANIFEROUS MAN.

Verneuil applies this term to the individual who carries the virus of tetanus

around on his person, although unaffected by the disease himself. The author discusses the causes and means of prevention of this affection from a clinical standpoint. If one considers the horse, with its secretions, excretions and surroundings, as all capable of propagating tetanus, we cannot regard as impossible, infection by the secretions and excretions of man. The tetanic property of equine saliva has been demonstrated. The saliva of a human being may, for the time being, contain tetanus germs, and thus a bite from such an individual may cause tetanus. A case is given illustrating this. The secretions and excretions are only infected by the ingesta, so that the sperm, milk and urine are never infected with the virus.

He says: "I have already admitted, and now I admit more than ever, that a surgeon, who has dressed a tetanoid patient, may communicate the disease to other patients. I also admit that any person whatever, but above all a physician whose hands have been in contact with a horse, not tetanic, but simply tetaniferous, may infect the wounds of his fellow beings, as in the cases cited. I also admit, finally, that such a man is not only dangerous to those whom he approaches but may even give himself tetanus by autoinoculation, either by wounding a part of the skin impregnated with the virus, as the plantar and palmar regions, or touching a wound on any part of his body with his impure hands."

Two cases follow, in which he traces the cause to a wound inflicted on the skin, which was previously infected with the tetanic virus. The bacillus of Nicolalier was found in one of these cases. Three additional cases are given with a very careful analytical study of each.—*Boston Med. and Surg. Jour.*

REGENERATION OF CORPUSCLES IN THE OLIGÆMIA FOLLOWING POISONING BY ACETYLPHENYLHYDRAZINE (PYRODIN.)

Modern research seems to show that in all the infective diseases, both acute and chronic there is a destruction of the red blood corpuscles, and that the work of regeneration by the blood-forming organs is also interfered with more or less gravely by the same morbific influence, this taking place much more slowly than it does in an otherwise healthy person after loss of blood from hæmorrhage. There is this difference between the two conditions. After loss of blood by hæmorrhage, the total volume of fluid in the vessels is rapidly made up by influx of serum from the lymphatics, and the organism only suffers from a temporary diminution, whereas, after destruction of corpuscles, there is not only loss of hæmoglobin, but the presence in the vessels of quantity of albuminous matter and pigment, which has become so much foreign matter. This matter becomes gradually collected in the spleen and marrow of bones, which thus has to fulfil both a hæmatopoietic and an eliminative function. It occurred to Professor G. Mya (*Riforma Medica*, April 28th, 1891) that this eliminative function might interfere with the regenerative duties of these organs. To test this he administered to several animals doses of pyrodin—a substance well known to produce destruction of corpuscles—and compared the time necessary for the restoration of the normal corpuscular richness with that required after extraction of blood from similar animals. He found, however, that very little difference occurred in the two cases, and that regeneration was, if anything, somewhat more rapid in the poisoned than in the non-poisoned animals. Some observations carried out in man, in which the action of the drug was carried to a much slighter extent, entirely confirmed the above results. From this it would appear that the original theory is untenable, and that in infectious diseases the virus itself exerts some direct injurious action on the reparative functions of the blood-forming organs.—*Brit. Med. Jour.*

THE DELIRIUM OF INFLUENZA.

The severe type assumed by the present epidemic of influenza is illustrated by the occurrence of many instances of marked delirium. Reports of several such cases reach us from the midlands. In one very extraordinary case a barmaid, suffering from influenza, was found by a policeman, lying on the pavement, having nothing on but her night-dress. It is supposed that while in a delirious condition she fell through the bedroom window, which was in a second story. If the facts are as represented she must have fallen from a height of fifty or sixty feet, and the extraordinary part of the affair is that she does not appear to have been much hurt, and only complained that her heels were very sore. When questioned about the occurrence, she says she has no recollection of how she fell out of the window. Another case was that of a farmer of Longor, near Buxton, who was suffering from a severe attack of the malady. During the night he became delirious and escaped from the house,

and was smothered in a heap of manure before his wife could obtain assistance. The third case was that of the postmaster of Ravenstone, near Ashby-de-la-Zouche, who had become much depressed, and, showed symptoms of brain affection during an attack of influenza. His wife missed him early one morning and communicated with the police, who found his body, partially dressed, in a well. The occurrence of these cases should put medical men on their guard, especially where there is any tendency to melancholia or depression on the part of patients.—*Med. Press.*

CHANGES IN THE KIDNEY IN PHTHISIS.

The condition of the kidneys in phthisis has never been fully investigated. Several observers have described a fibroid condition. Becquerel and Rayher concluded that Bright's disease was very frequently associated with tubercular disease of the lungs. Peacock in 117 cases of kidney disease found 30.7 per cent. of phthisis. Frerichs found that out of 42 cases of Bright's disease 6 also suffered from phthisis. Bamberger stated that the disease was found in 15 per cent. of those suffering from kidney disease. In the *Centralblatt für Allgemeine Pathologie und Pathologische Anatomie,* Feb. 1st, 1891, Dr. C. von Kahlden publishes his results on the same subject. He is of opinion that slight degeneration of the renal epithelium is almost always found in active phthisis. It may, however, be so slightly marked that it is only visible on microscopic examination, and even then may be easily overlooked. The kidney may be either normal in size or somewhat enlarged. Microscopically the following conditions are noticed. The surface of the organ is smooth and yellowish in color; the capsule peels easily; the cortex is usally slightly thickened, and also yellow in color; the medullary portion is pale. The microscopic changes chiefly affect the cortex, the parenchyma being first attacked. The epithelial cells undergo fatty degeneration, but are occasionally replaced by fresh epithelial cells. The interstitial changes are therefore secondary, and generally slight, and take the form of a small round-celled infiltration, and some increase of the connective tissue. The glomeruli also take part in the degeneration. The cortex is not uniformly affected, but the changes take place in patches. These lesions are evidently chronic, as is shown by the thickened capsule, the atrophy of some of the glomeruli and the changes in shape of the epithelial cells of the tubules, these being altered from a club form to a cubicle or cylindrical shape. Clinical symptoms which accompany the renal degeneration are unreliable. Albumin in the urine is rarely present. The author states that the condition is one of chronic parenchymatous nephritis, and thinks that it may be caused by the poisonous products of the tubercle bacilli.—*Lancet.*

THE PRESYSTOLIC BRUIT.

Professor I. Cantalamessa, of Bologna (*Riforma Medica,* May 5th, 1891) says the presystolic *bruit,* which a Bolognese professor (Brugnoli) was one of the earliest to study (1859,) is still by some regarded as pathognomonic of mitral stenosis. Flint, however, reported three cases of aortic insufficiency, in each of which a presystolic *bruit* was distinctly heard as well as the diastolic, but in which the mitral valves were found intact after death. His explanation was that the chordæ tendineæ of the mitral valve vibrated owing to increased tension during the auricular contraction, because the ventricle received blood both from the aorta and from the auricle. Keit thought that the murmur was of aortic origin, due to the great difference of tension between the loaded ventricle and the empty aorta at the moment of beginning of systole. But if so, Cantalamessa maintains, the *bruit* should be heard over the base of the heart, not the apex. De Renzi gave as the cause, the meeting of the two currents of blood, one (abnormal) from the aorta, the other (normal) from the auricle. But this and Flint's hypothesis are, in Cantalamessa's opinion, open to the grave objection that if either were true, a presystolic *bruit* ought to be very common in aortic insufficiency, which it is not. Nor is it heard in cases of great insufficiency, but only in rare cases, and then strictly localized over the apex. This suggested to Grocco the following theory: The regurgitation varying in amount and direction according to the degree and seat of the aortic lesion, if only one semilunar valve fail to act, the current backward will be oblique, and if directed posteriorly will cause the anterior bicuspid valve to become tense, and vibrate against the stream coming from the auricle, the brief auricular systole aiding. Further, if the backward current does not strike against the valvular cusp, it will still impinge against the ventricular wall, and in certain cases be reflected against the auricular current. After reference to the views of Dickinson, Constantin Paul, and Fenwick and Overend, Cantalamessa

proceeds to examine why the first sound is strong in mitral stenosis, and weak or even absent in aortic regurgitation. The first sound is normally caused by, 1 the heart muscle, 2 the atrio-ventricular valves, 3 the arterial distension. Which of these three will explain by its alteration the phenomena just mentioned? Certainly not the first, for in mitral stenosis the left ventricle is not hypertrophied; nor the last factor, namely, arterial distension, because in the same disease the pulse is small. There remains valvular tension as the cause. The more suddenly the valves pass from extreme relaxation to great tension, the more readily will a sound be produced. Now in aortic insufficiency the refluent strain tends to make tense the valves gradually, so that in this final closure there is no abrupt change, and hence the first sound is weak or absent; but in mitral stenosis, owing to the negative pressure in the left ventricle, the valves are at one time extremely relaxed and then suddenly stretched, which causes a short and sharp first sound. As regards the presystolic *bruit*, Cantalamessa concludes that: 1 The *bruit* heard immediately before the first sound in mitral stenosis, in double mitral disease, and (occasionally) in aortic insufficiency, is really a presystolic *bruit;* 2 it is not pathognomonic of mitral stenosis; 3 its presence warrants the diagnosis of mitral stenosis only when a careful examination of other physical signs allows the exclusion of aortic insufficiency.—*Brit. Med. Jour.*

THE ANAL REFLEX.

Rossolimo says this reflex consists in a contraction of the anal sphincters in response to a stimulation of the skin and mucus membrane of the anus. It is invariably present in man in health. The branches of the inferior hæmorrhoidal, pudendal, and perineal nerves, on which this reflex depends, are connected with the third and fourth roots of the sacral plexus, which spring from nerve cells in the conus medullaris. This reflex can be obtained in the dog as well as in man, and Rossolimo cut the spinal cord across at different levels from above downwards; whenever the lumbar enlargement was cut across at the level of entry of the third sacral nerve, the anal reflex suddenly disappeared, from which it follows that the cells of the spinal cord which are connected with this reflex are situated in the third quarter of the lumbar enlargement, reckoning from above downwards. In another series of experiments the lumbar enlargement was exposed, and the sacral roots were cut one at a time. By this means it was proved that the anal reflex depended upon the integrity of the third and fourth sacral roots. This reflex, therefore, has its seat in the cord lower than any other reflexes. To obtain the anal reflex the patient may be either standing, the operator separating the glutei, or lying on his side with the legs drawn up. The skin and mucus membrane of the anus may be stimulated by stroking with a pin, a feather, a piece of paper, or some suitable object. The reflex is shown by a contraction of the sphincter ani externus, and if it is very strong there is a drawing in of the whole anus, and even sometimes a contraction of the glutei. In women the testing of this reflex may be conveniently combined with a gynæcological examination. The author has examined this reflex in a great many conditions, and he comes to the following conclusions: It is increased in some cases of neurasthenia, in cases of myelitis high up in the cord, and in conditions in which there is a general exaltation of sensations. It is lost in multiple, neuritis affecting the sacral plexus, in some cases of tabes, and in myelitis of the lower part of the cord, and in these cases there is generally also anæsthesia of the rectum, anus, and urethra. It remains normal in functional derangements of the bladder, the rectum, and the sexual apparatus.—*Boston Med. and Surg. Jour.*

AN AID TO PALPATION.

Chlapowski finds that for palpation of tumors of the abdomen an excellent method is to put the patient into a well-filled bath tub. The advantages gained are several: the reflex contraction of the abdominal walls is overcome; it is very easy to change the position of the body without exertion on the part of the patient; and the pain on pressure is diminished. The author has had especially good results in determining the nature of tumors in the region of the cæcum, and in mapping out infiltration due to old appendicitis. He has also been able to determine the nature of floating kidneys, splenic tumors and different new growths, where previously the contraction of the abdominal muscles had prevented satisfactory examination.—*Ex.*

GOUT, MELANCHOLIA AND HIGH ARTERIAL TENSION.

Dr. H. Willoughby Gardner records in the *Lancet* the following case: W. W.—, first

seen on March 3d, 1891, when suffering from a mild attack of acute gout in the left foot. He had had many previous attacks, and had been troubled with gouty dyspepsia. After two or three days the local manifestations disappeared; the patient considered himself to be well, and proposed to return to work at the beginning of the next week. On the morning of March 9th he was found to be suffering from acute melancholia, chiefly of a religious type. The day before (Sunday) he had attended three long religious services, and had taken no exercise. A note which he wrote to his sister contained accusations and mis-statements which were apparently due to delusions, and, in addition, threats of suicide. When seen in the evening he wore an expression of settled melancholy. When questioned, he confessed to wishing to commit suicide, but said he knew it to be wrong. On examining his radial pulse, it was found that the beat was very weak, the wave being easily stopped by the finger; the artery, however, remained full between the beats, though it could be easily flattened out by pressure. On listening over the cardiac area the first sound at the apex was found to be short and weak, while the second sound in the second right intercostal space was loud and of a peculiar ringing character. It was thus seen that he presented the condition of "virtual tension" so well described by Dr. Broadbent.

There was great peripheral resistance, and with it, signs that the left ventricle was flagging and becoming unequal to meet fully the increased work thrown upon it. The probable consequence was that the movement of blood in the brain was extremely sluggish, and hence its cortical cells were not receiving a due supply of oxygen for healthy action. A mercurial purge was at once given. A strong mustard plaster—pushed so as to cause a blister—was applied to the nape of the neck, and his feet were put into a hot bath of strong mustard and water. He states that the mustard plaster caused very great relief in less than half an hour. In the middle of the night he was seized with a slight attack of gout in the left foot. At once all depression completely disappeared. It was replaced, indeed, by a certain amount of irritability, but this in its turn wore away as the pain in the foot ceased. When seen on the evening of the 10th the patient was in excellent spirits, and said he felt perfectly well. The radial artery could no longer be felt between the beats, and the pulse wave seemed considerably stronger. On listening over the cardiac area nothing abnormal about the heart sounds could be detected. The accentuated ringing character of the second sound had completely disappeared—indeed, it was not so loud in the right second intercostal space as in the left,—while the first sound at the apex seemed in every respect normal. With a view as much as possible to prevent the recurrence of undue tension, or, it may be said, of gout, careful directions were given as to diet and rigimen, special attention being devoted to his mode of life on Sundays. These directions have, Dr. Gardner was told, been carried out. The patient has kept in excellent health since, and states that his spirits have been better than they had been for some years.

SURGERY.

THE TREATMENT OF VARICOSE VEINS.

Dr. William Taylor said the treatment he advocated was blistering. He had discovered its good effects accidentally when treating a case of gout by means of blisters, and had since tried it in many cases with considerable success, and found it especially useful in old people. He considered blistering to be "eminently restorative" in varicose veins. Dr. Taylor did not believe in elastic stockings, and considered operative treatment unscientific. He supposed that the coats of the veins participated in some way, which he could not explain, in the restored vitality set up by the action of the blisters. He found that the veins remained sound for several years, but were then apt to become distended again, and require the treatment to be renewed. Its great advantage was that it could be used in cases where palliative treatment was contraindicated, and that it always did good to the solid œdema so often associated with the varicose condition. The details of the treatment were as follows: 1. Remove the cause. 2. Obviate the tendency. 3. Elevate the limb for twenty-four hours. 4. Blister from the foot upwards, six inches daily, watching the kidneys and bladder. First paint the part with Rubini's tincture of camphor, then with blistering fluid, and lastly with collodion. The blisters must rise and serum be withdrawn to do good. 5. When whole limb is blistered, apply plaster to the whole length of the vein for two weeks. 6. Remove the plaster and see what is the result of the treatment. If the veins bulge, blister again, if they are all right apply

more plaster, and allow gentle exercise for a week. If at the end of that time the veins are still in good condition, no further treatment is needed.—*Med. Press.*

IODOPHENIN: A NEW ANTISEPTIC.

A. Scholvien has found (*Pharm. Zeit.*, No. 40) that when a cold-saturated solution of phenacetin, acidulated with hydrochloric acid, is treated with iodine, a gray precipitate forms which afterwards appears as a mass of crystalline needles. It forms, when dry, a chocolate-brown powder. When recrystallized from glacial acetic acid, it may be obtained in steel-blue crystals.

In preparing this substance on a large scale, it would be necessary to operate with very large quantities of liquid, if a mere aqueous solution of phenacetin were employed. This is avoided by dissolving the phenacetin in glacial acetic acid, and afterwards diluting with water.

The resulting product, called *iodophenin*, melts at 130° C., decomposing at the same time. It contains one portion of its iodine in a more intimate combination than the other. It is soluble in 20 parts of cold glacial acetic acid, more easily in the same liquid when hot, and is also soluble in alcohol. It is but slightly soluble in benzol and chloroform, and insoluble in water. If heated with water, it is decomposed.

Wittkowsky has found that this substance is a most efficient bactericide.—*Amer. Drug.*

ENTIRE EXCISION OF THE TONGUE.

In the issue of May 2, 1891 of the *British Medical Journal*, Walter Whitehead reports one hundred and four cases in which complete removal of the tongue was practised for carcinoma of this organ. The mortality in these cases from the operation was 19.21 per cent. The age of the patients ran from fifty-six to seventy years. The cases included those in which the disease was far advanced, as well as those less seriously affected. No attempt was made to select the cases for report.

The following short description of the technique is given:

1. The patient should be completely under the influence of the anæsthetic during the first stage of the operation, but afterwards only partial insensibility should be maintained.

2. The mouth should be securely gagged and kept fully open throughout the operation.

3. The head should be supported in such a position that, while the best light is secured, the blood tends to gravitate out of the mouth instead of backward into the pharynx.

4. A firm ligature should be pressed through the tip of the tongue for the purpose of traction.

5. The first step in the operation consists in dividing the reflection of the mucus membrane between the tongue and jaw and anterior pillars of the fauces.

6. Rapid separation of the anterior portion of the tongue from the floor of the mouth.

7. Securing, if possible, the lingual arteries, with Spencer Wells' forceps, prior to division.

8. Passing the ligature through the glosso-epiglottidean fold, before finally separating the tongue.

9. The application of a mercurial solution to the floor of the mouth, followed by painting the surface with an "iodoform styptic varnish."

He recommends early operation, chloroform for an anæsthetic, and the mouth to be kept very widely open. It is advised to have the patient sit up from the first, and to walk about should the weather be fine. Scissors are used in preference to other instruments.

The ultimate results have always been unsatisfactory, but the author believes that the operation frequently prolongs life, or, failing in this, renders the patient's last days more comfortable. One of the patients survived the operation fourteen years, although he was sixty-two when operated upon.

The latter part of the article is devoted to the predisposing causes of the disease (carcinoma) for which the operation was done.

MODERN RENAL SURGERY.

In No. 16 of the new series of the *Sammlung Klinische Vorträge*, Dr. A. Obalinski, of Cracow, deals, in the first place, with the subject of rupture of the kidney as an indication for nephrectomy (SUPPLEMENT, May 16th,) and next reports cases of suppurative paranephritis, of calculous pyonephritis, and of ureteral fistula. The author sums up his views regarding the treatment of severe inflammatory affections of the kidneys and their sequelæ in the following conclusions: 1. Suppurative inflammation of the kidney and surrounding structures indicates the operation of nephrectomy in order that free exit may be given to the purulent and other inflammatory excretions, and that the focus of the disease may be thoroughly cleansed, and fur-

ther extension of the suppuration to important parts, as, for example, the thoracic and abdominal cavities and the hip-joint, be thus prevented. In most cases the single lumbar incision, as was performed by Simon, will suffice, but when there has been extensive undermining of the peritoneum the formation of a large flap, as practised by Bardenheuer, is to be preferred, as such operation permits of ready access to all extensions of the main pus-containing cavity. 2. Ureteral fistula should always be treated by removal of the corresponding kidney, provided the surgeon can assure himself of the existence of a sound renal organ on the other side. Nephrectomy in such cases is indicated, not only on subjective grounds and when, for instance, the external flow of urine cannot be restrained by any apparatus and the patient is thus prevented from following his occupation and from enjoying a comfortable existence, but also on objective grounds, since, notwithstanding the utmost precautions, an old ureteral fistula may result in suppurative inflammation of the corresponding kidney and of the adjacent soft parts. 3. Nephrectomy performed under these last-mentioned conditions offers much less favorable prospects than in cases in which there is an absence of suppuration or of cicatricial adhesions. 4. There can be no doubt that, under equally favorable conditions, the transperitoneal method can be performed more rapidly and with greater ease than the extraperitoneal method of nephrectomy, and that the progress towards recovery is more speedy after the former operation. The transperitoneal method, however, is not applicable to every case, and should be reserved for those instances in which the mischief is confined within the capsule of the kidney, the extraperitoneal method being indicated when the suppurated process has involved the perirenal structures.—*Brit. Med. Jour.*

A PIECE OF GLASS IN THE LARYNX FOR TWENTY-ONE MONTHS.

A remarkable instance of the tolerance of foreign bodies exhibited occasionally by the larynx, is recorded by Dr. C. C. Richardson, of New York, who succeeded in removing the offending substance after it had remained in its position more than a year and nine months. The patient was a lady, who, while at lunch in October, 1888, was suddenly seized with a violent fit of coughing which continued for more than half an hour, and seemed to threaten immediate suffocation. Careful examination at this time failed to reveal the presence in the throat of anything to account for the paroxysm, and it was assumed that whatever body had excited it had been subsequently swallowed. The patient, however, was for a long time ill, and was constantly troubled with a cough, laryngeal irritation, and loss of voice, and after enduring this state of things for twenty-one months she came under the care of Dr. Ransom. Laryngoscopic examination then revealed the presence of a thin piece of glass suspended antero-posterially between the vocal cords, the body of the glass swinging free in the glottis; an explanation of the distressing symptoms so long experienced was thus afforded. After brushing the larynx with a four per cent. cocaine solution Dr. Ransom was able to remove the foreign body with the aid of the Schrötter forceps, and it was then found to be part of a wine glass, triangular in shape, and measuring along its three borders seven-eighths of an inch, one inch, and one and a quarter inches, respectfully. Immediate improvement in the voice and relief of irritation ensued on removal of the glass, and the larynx quickly regained its normal healthy condition.—*Med. Press.*

THE TREATMENT OF MALIGNANT NEOPLASMS BY ANILINE INJECTIONS.

Prof. Mosetig-Moorhof (*Wiener klin. Wochen.*, March 19, 1891, p. 224) presented two patients. One had a myeloid sarcoma of the chin; all visible traces of the new growth had disappeared. She had received in all fifty injections of methyl-violet solution, one to five hundred. About 120 grammes of the solution were used. The other case, a man, had had a cysto-sarcoma of the sternal region. It completely disappeared. The sarcomatous infiltration of the muscles has, through retrogressive metamorphoses, subsided, leaving a few nodes, the size of beans, which are regarded as the residue of the stroma, *i. e.*, connective tissue. This patient had received twenty-one injections, or sixty-three grammes. He reported the case of a woman, aged 47, with an epithelioma of the nose. She had been under treatment thirty-four days; had received nine injections, each of three grammes, and was considerably improved. Another case, male, aged 58, affected with carcinoma of the tongue; had had twenty-six grammes of the methyl-violet solution injected into the tongue and on the floor of the mouth. Marked improvement followed. Out of sixteen in-operable cases, two died, and fourteen have been improved. Any in-

crease or dissemination of the neoplasm following the injections has never been seen. The injection treatment is not suitable for very vascular tumors, and should not be employed for those which spring from an inaccessible base, or such as require the needle to pierce a large serous cavity in order to reach them. The solution used is one to five hundred methyl-violet, and should be filtered through asbestos which has previously been heated to a red heat. A three-gramme syringe, with needles of various lengths is employed, and three to six grammes are injected every second or third day, mostly from the periphery toward the center. In ulcerated neoplasms the needle should be introduced at a distance from the ulcer. Bad results from these parenchymatous injections have never occurred—at most, there has been a slight redness or œdema.

Discussion.—Prof. Billroth did not consider Mosetig's cases as complete cures. A new growth can only be counted cured when all specific tissue elements have ceased to exist and been harmlessly resolved, and the previously in filtrated tissues remain as simple scars. There are but two new-growth diseases which we can heal, viz., syphilitic, by means of mercury, etc., and malarial, by means of quinine, etc. Billroth says: "I have treated a large number of cases by Mosetig's method, and three I recall perfectly. They were large, non-ulcerated sarcomas. I can only say that all three were made worse. In the treatment of ulcerated carcinoma by methyl-violet paintings and injections, the results were also unsatisfactory. As regards the two cases given, the woman still has a tumor remaining. While it may be, as has been said, that it cannot contract any more, nevertheless it has not entirely disappeared, but has only been reduced in size. In reference to the other case, we only saw it as a softened, ulcerating mass, and cannot say whether it was tuberculous, syphilitic or sarcomatous. The result is good, but there still remains a thick, diffuse infiltration of the tissues, and before this has disappeared we cannot speak of a cure."

Prof. Mosetig, in reply, stated that the case alluded to was undoubtedly a sarcoma, and that even if his two cases were not regarded as cured, it could not be denied that their condition had been very much improved.

GYNÆCOLOGY.

THE RESULTS OF THE REMOVAL OF THE UTERINE APPENDAGES.

Dr. Keppler, at the Tenth International Medical Congress, gave the after history of eighteen cases, which he had followed up and carefully studied. In each of the patients the operation had been done for gross diseases of the sexual organs, such as pyosalpinx, salpingitis, oöphoritis, uterine myoma —and never for psychosis or neurosis. Both tubes and ovaries were always removed. The therapeutic effects were good, the patients in all cases being relieved of their symptoms.

The anatomico-physiological results were likewise uniformly good. In no case did a typical menstrual hæmorrhage occur after the operation. The countenances of the women remarkably changed, and the women became quieter and more beautiful (!). In all cases the conjugate diameter of the pelvis became shorter, this effect being more pronounced in the younger patients; the shortening amounted from two to three centimetres. The vagina became shorter and narrower, the mucosa thinner, smoother and paler. The cervix became shorter, the uterus smaller, the introitus vaginæ narrower. The breasts became smaller and the nipples paler. The tendency to become stouter which has been described by other operators was not observed in any case. The sexual instinct was always preserved. Three patients, virginal before operation, married later and lived in happy wedlock. The passions persisted, particularly when the operation was performed early on young persons. In myoma the results of the operation were good both as regards the hœmorrhage and the shrinking of the tumor.—*Boston Med. and Surg. Jour.*

THE TREATMENT OF RETROFLECTION.

Dr. Veit (*Festschrift d. Berlin. geburtshilf. Gesellschaft zum X internat. med. Kongress*, p. 59) notes that retroflexion of the uterus has become a surgical disease, and therefore, since all cases do not demand operation, precise indications for treatment must be laid down. Life is not endangered by this malformation; some retroflexions are readily cured by simple therapeutic measures; whilst, on the other hand, no operation can restore the uterus to position as long as it remains fixed. The most easy cases for permanent cure are those which occur before 30, whether in relation to the puerperium or from more obscure causes. For the results of abnormal labors and mismanaged puerperia are not the sole causes of retroflexion. That malformation is occasionally found in newborn children, and not rarely at puberty. Here cause and effect may be confounded, for the beginning of menstruation can

hardly go on so normally in a chlorotic girl with faulty position of the uterus as in a robust subject. In cases of retroflexion in young subjects the careful application of the pessary is sufficient treatment, and half the cases so treated will be permanently cured after wearing the instrument, frequently changed, for about a year. The operations are ventro-fixation, shortening of the round or utero-sacral ligaments, and Schücking's vaginal hysteropexy. The results are at the best faulty, for they cannot make the uterus move freely, at the same time that it lies in a good position, between other viscera, bladder, intestines, etc. As long as a retroflexion is movable, it requires but little treatment in a woman past the change of life. The pessary will act best when the uterus remains bulky and not atrophied. In virgins it is often best to dispense even with pessaries, and turning their attention to the condition of their genitals is most objectionable; the nervous system, if fortified by any means which divert the patient's attention from the local affection will allow the trifling discomfort of the retroflexton to be well tolerated. Massage is of questionable value; it may increase the patient's nervousness, which is worse than the displacement. When pessaries are used, they will best avail if any pre-existing endometritis or metritis be cured. Fresh retroflexions after child-bed are the most favorable for treatment. Ergot should first be administered, nor should the pessary be applied till the eighth or tenth week, and when the instrument is changed a smaller pessary should be applied. Cutting operations are only justifiable when pessaries cannot be borne and do no good. Retroflexion with fixation of the uterus may be left alone in a sterile subject; in a patient anxious to bear children and also suffering from the malformation the case is different. The operations above mentioned have not been so generally adopted as to allow of judgment on their justifiability. Schücking's vaginal hysterectomy, which binds the fundus down forwards behind the bladder, is bad on theoretical grounds. Freund and Frommel's shortening of the utero-sacral ligaments and forming of adhesions in Douglas' pouch is more in accordance with reason.—*Brit. Med. Jour.*

OBSTETRICS.

INFLUENCE OF SULPHATE OF QUININE UPON THE GRAVID UTERUS.

Dr. Bertrand, of Vracene, in summarizing a series of experiments, states that sulphate of quinine exerts no unfavorable action upon the pregnant uterus, and that he has never known it to be the cause of an abortion. He has, however, frequently observed that when labor has already set in the uterine contractions can be materially strengthened by exhibition of this drug. Indeed, in cases of premature birth where uterine douches and the introduction of bougies failed to produce active labor, quinine would frequently have the desired effect and hasten delivery. Bertrand also found the drug of signal service in the after-birth period of labor, especially when an atonic condition existed, as well as in post-partum hæmorrhages and sub-involution of the uterus during the lying-in period.

Bertrand gives the drug in single doses of one gramme, but under certain circumstances increases this to two or even three grammes. When the patient is unable to take the drug per os, Dr. Bertrand advises its use hypodermically or as an injection.—*Allgem. Medicinische Central-Zeitung.*

ELEVATION OF THE PELVIS AS A MEANS OF RELIEVING VOMITING OF PREGNANCY.

Sir James Grant, M. D., writes:

In 1877 I was called to attend a lady in her first pregnancy, about the third month of utero-gestation. I learned that for fully ten days she had been unable to take food, and with great difficulty retained even the smallest quantity of liquid nourishment. Almost every form of treatment had been tried without any apparent good result. As a last expedient, I decided to test the effect of elevation of the pelvis, which was accomplished by lowering the head and thorax, and placing several pillows under the sacrum. In a short time the change for the better was encouraging, and continuing the position at intervals for a few hours, in two days the marked improvement in the system was quite evident, and utero-gestation proceeded to the full term without any return of this abnormal condition.

Within the past month, two cases of severe vomiting in early pregnancy came under observation, in both of which I adopted the same treatment, with equally satisfactory results.

Guémot, referring to the rational treatment of vomiting during pregnancy, says that a morbid or abnormal state of the uterus, the nervous system, as the carrier of reflex action, and the stomach, are the prime factors in the malady. The idea of Smellie's,

that the complaint is "chiefly occasioned by fulness of the vessels of the uterus," certainly is most rational. The elevation of the pelvis gradually lessens the quantity and force of the blood in the uterine vessels, and thus reduces the quasi-irritability, or, as Dr. James Stewart of McGill terms it, "the instability of the nerve elements" in the uterine nervous system, the abnormal influence of which, prior to the change of the pelvic position, had been rapidly telegraphed to the spinal and gastric nervous centres.—*Exchange.*

THE VAGINAL OPERATION IN EXTRA-UTERINE PREGNANCY.

Dr. Christian Fenger, in the St. Louis *Med. and Surg. Journ.*, reaches the following conclusions:

1. In case where the fœtal cavity is still aseptic, the vaginal operation exposes the patient to danger of sepsis in the fœtal sac, which cannot be guarded against. Abdominal section gives far better means of protection against septic infection.

2. Hæmorrhage from the placenta cannot be controlled by the vaginal operation. By abdominal section, on the other hand, ligation of the internal spermatic and uterine arteries, as devised by Olshausen, can be accomplished as a means of checking hæmorrhage from the site of a removed placenta in the territory supplied by these vessels. Abdominal section further permits of ligature *en masse* of the bleeding portions when the placenta has been divided at the place of incision.

3. Delivery of the child at full term is usually difficult, and thus dangerous to the mother, by the vaginal operation, but easy by the abdominal operation.

4. If the fate of the child is to be considered, the vaginal operation must be abandoned and replaced by abdominal section.

5. When suppuration has set in in an extra-uterine pregnancy presenting low down in the small pelvis, and the placental circulation has ceased, the vaginal operation may be considered in comparison with the abdominal operation.

6. The vaginal operation is strongly indicated in old suppurating fœtal sacs, with disintegrated fœtus presenting in the vagina.

Final Remarks.—The vaginal operation is condemned by a number of modern authors, among whom may be mentioned Werth, Olshausen, Lawson Tait, Thornton, and others. At the Gynæcological Congress at Freiburg in June, 1889, Olshausen condemned the vaginal operation as well as drainage into the vagina after laparotomy in such cases.

As an advocate of the vaginal operation Landau stands isolated. He stated that he had performed thirteen vaginal operations and lost only one mother. As his cases have not been published in detail, this material is not available for consideration here, and can have no influence on the conclusions above stated.

PÆDIATRICS.

EXALGINE IN PÆDIATRICS.

Dr. Moncorvo, in the *Bulletin Géneral de Thérapeutique*, reports a series of cases illustrating the beneficial action of exalgine in various painful affections in children. Without exception the drug was always well tolerated. In not a single instance did it produce those unpleasant symptoms so frequently seen to follow its use in adults, such as apparent drunkenness, roaring in the ears, darkening of the face, etc. The remedy was given to the children in doses ranging from 5 to 30 centigrammes. As the drug does not taste badly, it was given in substance, or administered in a little wine.

In all cases the action of exalgine was far superior to that of antipyrin, as in medium doses it acted equally as well as five times the same quantity of antipyrin.

In one case of incipient chorea in a little girl, the choreic movements ceased entirely after five days' use of the drug; 20 centigrammes having been given daily. On the strength of his observations, Dr. Moncorvo strongly recommends the use of exalgine in pædiatrics.

PROGNOSIS IN DIABETES.

At the Congress für innere Medizin (*Deutsche med. Zeit.*, 40) Sandmeyer, of Marburg, made some observations on a case of diabetes in a child who died comatose two years after beginning to suffer from the disease. Although the urine presented only traces of albumen, it contained an unusual number of casts, mostly granular. Sandmeyer has noticed in a series of cases of diabetes before and during the coma the appearance of casts in the urine previously free from casts; the casts are very short, generally hyaline, but sometimes granular, and disappear as the symptoms of coma pass off. The amount of albumen in such urines

is very small. In the case reported hyaline and granular, casts were found in some tubes, and extensive fatty degeneration of the epithelium. Degenerative changes were also found in the spinal cord, involving the anterior third of the columns of Goll in the cervical enlargement, and to a slighter extent the middle third. The pancreas was quite normal.—*Brit. Med. Jour.*

MASSAGE IN PÆDIATRICS.

Massage is an art, and, like every other art, requires study and patient preparation for its successful practice. It is a powerful remedy too, and, like other agents of its class, as potent for evil as for good in unskilled hands. Therefore, to insure good results, a trained masseur is necessary, and she must act under the directions of the physician. Before entering upon the therapeutic application of massage proper, it will be well to revert to the process of simple rubbing. This is of much value as a general hygienic measure. Each day after the bath, the skin having been thoroughly dried by a soft, warm towel, the whole surface should be gently rubbed with the palm of the hand, the process occupying about five minutes. This increases the capillary circulation, encourages thorough reaction, aids nutrition, and adds vigor to the frame. Weakly children, especially, thrive under it. In older children, friction with a soft towel may be substituted for the hand-rubbing, but the change should not be made before the fifth or sixth year.

Massage may be employed with advantage in the following diseases of childhood :

(*a*) *Chronic gastro-intestinal catarrh.*—In this condition the skin is harsh and dry, the muscle-tone is faulty, general nutrition is impaired, and there is a determination of blood from the surface towards the mucus membrane. A warm bath is administered every evening just before bedtime, the patient remaining in the water for five minutes; then the surface is thoroughly dried, and half an ounce of olive oil is gently rubbed into the skin ; the child is then enveloped in a light blanket and put to bed. After a little time diaphoresis begins. So soon as the sweating is free, the skin is again dried and the night-dress put on in preparation for sleep. Next morning the child is subjected to twenty minutes massage.

(*b*) *Constipation.*—Manipulation is a very efficient remedy in habitual constipation. The best method is to follow the natural course of the fæces through the colon ; thus, beginning in the right iliac region, proceed upward to the right hypochondrium, cross over to the left hypochondrium, and then downward to the left iliac region. Five or ten minutes every morning, or every morning and evening in obstinate cases, constitutes the proper duration and frequency of the applications. The pressure must be gentle, as delicate tissues are being dealt with. In this condition the combination of massage with the inunction of warm olive oil or a weak ammonia liniment is more efficient than the dry method.

(*c*) *Colic.*—Two or three minutes effleurage may be resorted to, as the urgency of the symptoms require, with the most satisfactory effect. In this connection it must be remembered, also, that rubbing the feet, to increase the circulation there, is an important aid in relieving colic.

(*d*) *General debility and anæmia.*—These conditions are much benefited by short, frequently-repeated courses of massage. Manipulation improves the general condition, and strength is rapidly gained.

(*e*) *Infantile Paralysis.*—Here massage of the paralyzed muscles brings more blood into them, and maintains their nutrition until, in favorable cases, new cells in the cord take on the functions of those which have been destroyed. In recent cases the sittings should be of short duration and frequently repeated, five or ten minutes three to four times daily. As improvement advances, the frequency may be reduced, and in chronic cases twice a day will be sufficient at any time. Electricity is of great aid, but it should not be used until about three weeks after the onset of the paralysis, earlier application being attended by the risk of increasing spinal congestion.

(*f*) *Chorea.*—At the onset of the attack the patient is put to bed, given a good supply of good food, and allowed to rest for two days without massage. At the end of this time the regular treatment is initiated. The child, at seven years of age, for example, has at 5.30 a. m. half a pint of warm milk ; 7 a. m., half a pint of milk and three slices of bread and butter (each slice an ounce in weight) ; 9.45 a. m., a teaspoonful of Merck's dry malt in a little milk . 10 a. m., massage for fifteen minutes, followed by half a pint of warm milk ; 12.30 p. m., a teacupful of rice pudding, half a pint of milk, green vegetables and mashed potatoes ; 4.15 p. m., half a pint of warm milk, three slices of bread and butter, and a lightly-boiled egg ; 7 p. m., malt as before ; 7.30 p. m., massage for fifteen minutes, followed by half a pint of milk. At

the end of ten days or a fortnight, the bread and butter is increased to four slices at 7 a. m., and 4.15 p. m., a lean broiled chop is added to the mid-day meal, and an extra pint of milk is distributed over the twenty-four hours. It is a golden rule never to hurry these patients out of bed. While carrying out this plan, recovery is more rapid under the use of Fowler's solution, administered in daily increasing doses.

(*g*) Other nervous diseases in which massage is employed with success are pseudo-hypertrophic paralysis, facial paralysis, neurasthenia, spinal irritability occurring in girls about the approach of puberty, and that ill-defined and painful condition so often encountered in young subjects, known as "growing-pains."

(*h*) Pleuritic effusions (serous,) fibroid pleurisy, enlarged lymphatic glands, and stiffened rheumatic joints are all benefited by rubbing. In these special instances all the manipulations are generally combined with the use of embrocations, though the curative effect cannot be attributed to the latter alone. In conclusion, those cases in which the manipulation is followed by a sensation of comfort or refreshing sleep are most benefited by it. On the contrary, those, cases which are stimulated derive little benefit, and perhaps positive injury, from the process.—*Dr. Louis Starr—Ann. of Gynæ. and Pæd.*

HYGIENE.

TUBERCULAR INFECTION FROM MILK.

A great deal has been recently said by many prominent members of the profession, concerning the inutility of adapting extreme measures for the prevention of tuberculosis, some of whom have held that both tuberculus meat and milk may be partaken of with impunity and without harm to the consumer. The following case, which we quote from the *Allgem. Medicinischen Central-Zeiting,* will be of interest to optimistic members.

The case was recorded by Dr. Ollivier in a recent meeting of the Academie de Médicine of Paris. The patient was a young woman, twenty years of age, with acute meningitis. The girl was of a strong constitution, and had no constitutional trouble. She had been educated at a boarding school. Upon inquiry, it was learned that within the course of a few years, thirteen pupils in the same school had been infected with tuberculosis, and six had died. The milk supplied to the school was from cows kept on the place. Upon examination these animals were found to have tubercular ulcers on their udders, and after being slaughtered were found to be generally infected by the disease.

THE PRODUCTION OF MYOPIA IN SCHOOLS.

In a recent number of *Graefe's Archiv für Ophthalmologie,* Dr. Seggel makes a very important contribution to our knowledge of this subject, especially in reference to Stilling's theory, that the form of the orbit is a potent factor in producing myopia. From a considerable number of measurements made on living subjects, Stilling found that the height of the orbit was less in myopes than in non-myopes, and he advanced the theory that this formation of orbit was one of the chief factors in producing myopia, for it resulted from it that other things being equal, the reflected tendon of the superior oblique would exert more pressure on the globe than if the orbit were high. When, as is not infrequently the case, this tendon has an approximately transverse direction, the combined pressure of the two obliques upon the plane of the equator, exercised during the period of growth, tends to produce elongation of the antero-posterior diameter.

Considering the inaccuracy of measurements made on the living subject owing to the varying thickness of the soft parts, as well as the fact that even with a low orbit, harm would only result when the direction of the tendon was almost transverse, and bearing in mind the possible co-existence of other factors, we are entitled to demand very full statistical evidence before accepting this theory.

Dr. Seggel's paper, containing, as it does, records of the measurement of 1,900 orbits, the refraction having been estimated in each case, is valuable from a statistical point of view, and he has, moreover, paid considerable attention to the age and sex of his subjects, and to changes occurring in the course of years. We have only space to quote his main conclusions. He found that in children under 10 years of age there was a distinct association between myopia and a low orbit; but that the increase in the height of the orbit when myopia has once been produced is more rapid than in non-myopic subjects, consequently at the age of about 13 the orbit is no longer any lower than in emmetropia, while in adults the myopic orbit is the highest. Striking results were obtained by

measuring the changes that occurred in a few years in the refraction. He found that of those who had low orbits, 44.72 per cent. became myopic, while of the other only 22 per cent. became so. It must be admitted that these figures tend strongly to confirm Stilling's view, that a low orbit has some influence in producing myopia; but Seggel himself admits that there must be other contributory causes, and probably use of the eyes upon near objects under unfavorable conditions is the most potent of these.

In connection with this part of the subject, our readers will do well to refer to the admirably practical papers read by Mr. Priestly Smith and Mr. Richardson Cross at the meeting of the Association at Birmingham, which are reported, together with the discussion on the subject, in the *British Medical Journal*, vol. ii, 1890, p. 723. Both authors agree that the most active cause in the producing myopia is prolonged convergence, a view that is quite consistent with Stilling's theory, since there must in addition to the exciting cause be some predisposing conditions to account for the fact that all children do not suffer although the conditions may be the same.

As regards the prevention of myopia, we are no doubt in many respects much better off than we were a few years ago. Our school buildings are better lighted, the desks and seats are better arranged, the books are better printed, and most teachers have some knowledge of the ill-effects of neglecting these precautions. On the other hand, the actual amount of work that we demand from our school children has enormously increased, and becomes greater every year. A large amount of home study is thus rendered necessary, and it may well be doubted whether in this way, at any rate among the poor classes, the effect of the improved school hygiene may not be more than neutralized.

It would be a great gain if the children could be divided into classes more in accordance with their physical fitness for resisting the injurious effects of over-study, than with their capability of acquiring knowledge which, though it may satisfy an inspector, will be of much less use to them in after-life than a pair of healthy eyes and a sound constitution.—*Brit. Med. Jour.*

TOBACCO AND PHYSICAL HEALTH.

STATISTICS GATHERED FROM YALE STUDENTS BY DR. SEAVER.

Dr. J. W. Seaver, the College Physician and instructor in athletics at Yale, has made a comparative study of the users and non-users of tobacco in the present Senior Class for the past four years, and from his measurements he forms the following table:

Average increase in	*Users of Tobacco.*	*Non-users of Tobacco.*
Lung capacity, liters..... .. (Or an increase 66 per cent. greater for non-users.)	.15	.25
Inflated chest, meters..... (Or an increase 19 per cent. greater for non-users.)	.0304	.0364
Height, meters..... (Or an increase 20 per cent. greater for non-users.)	.0169	.0202
Weight, kilogrammes..... (Or an increase 25 per cent. greater for non-users.)	.4	.5

With regard to the possible effect on scholarships these statistics were given: Of those who received Junior appointments above dissertations, 95 per cent. have not used tobacco; of those above colloquies, 87½ per cent have not used tobacco; of all who received appointments, $84\frac{3}{10}$ per cent. have used tobacco; of the entire class, 70 per cent. have not used tobacco.

Dr. Steaver says that these figures accord with statistics that he has kept for the past eight years, the greatest percentage of gain always being on the side of those who do not use tobacco. The greatest variation in the two years' widest part has not been more than 4 per cent. Some of the students who are classed among the non-users do smoke, but not oftener than once a week or at such long intervals that the tobacco is apt to have little or no effect on them. Dr. Steaver states that the prominent athletes do not smoke or otherwise use tobacco as a rule, Calhoun being the only exception in college. All the candidates for the crew abstain from tobacco. —*New York Times.*

SEA SICKNESS.

Sea sickness is one of those minor miseries of existence for which there appears to be no cure. Many have been loudly trumpeted but none have really succeeded in susceptible persons. As a matter of fact very little serious study has been given to the subject; persons who do not suffer are apt to despise those who do, and persons who do suffer are too glad to forget their misery to be disposed to give any thought to its source. Professor Rosenbach, of Breslau, has recently published a small monograph, the outcome of observations and study of the phenomena of sea sickness extending over ten years. He gives his experiences in the form of thesis,

which he uses as the basis of his explanations and arguments as to the nature of the disease.

His arrangement of facts is as follows: 1. The malady commences as soon as the vessel pitches, that is rotates on its transverse axis. 2. The rolling, that is rotation on its long axis, is less severe, but the combination of the two is very unfavorable. 3. The phenomena appear more quickly and are more severe the further the patient is from the middle of the ship. Persons sleeping are attacked, also small children and animals. In small boats without sails very sensitive persons may be affected, when sails are used sickness is more likely to occur. 4. A moderate amount of food in the stomach and a small quantity of alcohol is more likely to act as a preventive than an empty stomach. 5. The horizontal position on the deck acts in some degree as a preventive. 6. Anxiety and apprehension precede sickness, a certain exhibition of energy and resolution may in short voyages and with slight vessel motion control the tendency to sickness. Soft winds (for example sirocco), strong odors, etc., are unfavorable. 7. There are two categories of the affection dependent on individual predisposition; in one the head, in the other the abdomen is principally affected. Cases where both are affected are common.

In regard to intensity: (*a*) Some women begin to feel uneasy from the beginning of the voyage, in perfectly smooth conditions of the surface; they are pale, and have no appetite. There is a certain dread also. It is questionable if they are cases of sea sickness. Perhaps they represent the purely psychical form. (*b*) In another variety there is a general irritation of the nervous system during the whole voyage. The digestive organs are unfavorably affected. (*c*) This series forms a transitional variety. Slight motions of the vessel affect sensitive persons and produce sickness with general loss of appetite, indisposition to move or speak, and painful sensations in the head or abdomen. These symptoms are a delicate re-agent to the disturbing action of the vessel.

As to the *theories* of the disease, they are arranged under three heads: 1 The psychical theory, (so named by the author) according to which all the symptoms are produced through the action of certain sensory organs upon the consciousness, giving rise to uncomfortable or unwonted sensations or disturbed equilibrium. 2. The theory of disturbed equilibrium, according to which the permanent disturbances of equilibrium act as painful irritations to the contents of the skull and of the abdomen, and are thus the causes of the phenomena. 3. The theory of the disturbance of the circulation, according to which the disturbances of equilibrium and the swinging motions of the body produce circulatory disturbances in certain parts.

As regards the psychical theory, the arguments generally adduced in its favor are: 1. That the sight of the pitching vessels and of the up and down motions of the vessel favor the occurrence of sickness. 2. That the abnormal effects do not occur with the eyes shut. 3. That sleepers generally escape. This conclusion the author rejects, for he states that energetic will and closure of the eyes do not quite succeed in warding off the attack.

The action of visual disturbances in inducing the sickness he considers very important, but only secondary as factors in the result. That the sufferer may be roused from sleep in a full paroxysm of the attack; that children at the breast and young children suffer, though less than adults; and that horses, who in their boxes do not see the movements, also suffer—these facts prove, the author states, that the external mechanical influences alone must be the cause of the sickness. These facts, on which the author seems to rely for his conclusions as to the secondary importance of visual disturbances, if in themselves correct, do not appear to demonstrate that visual disturbances were absent in the cases mentioned, and it is to be remarked that in a note the author speaks of closure of the eyes or avoidance of the sight of the mast and bulwarks of the ship as being of great assistance in preventing the attack.

The third theory—that of circulation-disturbances—the author rejects. The second theory is particularly developed, and the disturbing effects of various kinds of unwonted movement are described and analyzed. Thus, it is shown that backward travelling may produce illness, pains, even vomiting. The motion in swings, the effects of circular motion are next described. The effects of rapid upward or downward motion have been particularly experimented on by the author in the rapidly-moving American elevators. The author thinks that he has discovered a new and substantial explanation of the action of external movement impulse by the phenomena observed in rapid elevators. It is found that in ascending with the eyes closed, no noise being heard, there is experienced a peculiar feeling at the epigastrium which goes off during the rise, say, of four or five floors, but re-appears the moment

the elevator stops. The same thing occurs when the elevator moves downwards, the sensation being felt only at the outset and on the arrest of the motion. In the motion of the elevator there occurs a sudden movement and sudden arrest of the movement, and the effect of this in producing the epigastric disturbance is held to be analogous to the effect of the motion observed in the vessel at sea. This explanation furnishes a theory which the author accepts, because it covers the ground to the necessary extent. Further, the author is led to the conclusion that the complex symptoms of sea sickness are due to the molecular disturbances produced by rapid movements arising from sudden change of direction of the motion, whereby a severe intramolecular shaking and irritation primarily acting on the cells and the protoplasm of particular organs is produced.

The immediate transition from one movement to another movement in a different direction is assumed to be the cause of the disturbances experienced. Thus the painful sensations in sea sickness, in the act of swinging, in the oscillation liable to occur in rapid railway journeys, agree in this, that the peculiar symptoms of irritation, the distressing feeling at the epigastrium, the cold sweats, the general feeling of illness, and the headache, appear at the moment when the direction of the movement changes.

As regards the cure of sea sickness, the authors consider that the only real cure is "custom." He speaks favorably of certain medicines as being often operative for very short sea voyages—quinine, antipyrin, bromide salts, cocaine, morphine, chloral, and other anæsthetics. He speaks with approval of the advice of older writers that the horizontal position at mid-deck should be taken before the voyage begins, and that a bandage should be tightly placed over the liver, whereby the intensity of the motion is diminished, and a certain degree of fixation of the abdominal contents promoted.

Professor Rosenbach has made a most valuable and suggestive contribution towards the sulution of the much-vexed question as to the nature and cause of sea sickness; and, no doubt, his views will excite discussion calculated materially to advance our knowledge of the subject.—*Brit. Med. Jour.*

MEDICAL CHEMISTRY.

INCOMPATIBILITY OF IODIDE OF POTASSIUM AND CHLORATE OF POTASSIUM.

M. Sohet (*Bull. de la Soc. de Phar. de Bruxelles*) has lately studied the incompatibility and toxic properties of iodide of potassium and chlorate of potassium. He was asked to prepare a potion whose formula was as follows: Iodide of potassium, 4 gm.; chlorate of potassium, 6 gm.; syrup of narceine, 50 gm., and distilled water, 200 gm. The solution was clear at first, but in a few hours it became cloudy, then turned to a yellowish hue and ended by taking on a brown coloration. His conclusion was that the combination of the two salts gave rise to iodate of potash, a toxic salt, and decided that this preparation should never be dispensed. On reading up the subject he found that M. Melsens, a professor of chemistry in Brussels, had once sent a communication to the Academy of Medicine, in which he stated that a mixture of 40 to 60 cg. of iodide and chlorate of potassium was sufficiently powerful to kill animals.

CHATININE, AN ALKALOID OF VALERIAN ROOT.

M. Waliszewski, a pharmacist of Clichy, has isolated an alkaloid from valerian, and named it chatinine, in honor of M. Chatin, late director of the Ecolé de Pharmacie of Paris. To obtain it, he removes from valerian root, by distillation, its valerianic acid and volatile products. Then he exhausts the root by decoction in distilled water, and clears the liquid with acetate of lead. The lead is eliminated by sulphuric acid or sulphuretted hydrogen. The filtered liquor is evaporated to the consistency of a soft extract, which is treated by 90 per cent. alcohol. The filtrate is distilled and the residuum is taken up with distilled water; this product is distilled to the consistency of an extract, and treated with bicarbonate of soda and ether; the ether is washed with distilled water; the liquid is now evaporated, and the residuum, which is chatinine, is treated by an acid, preferably hydrochloric. As valerian root contains an ammoniacal salt, which remains with the chatinine during the above operations, the product must be treated with 95 per cent. alcohol, in which the chloride of ammonia remains insoluble. The chatinine salts have the general characters of the alkaloids, and, like them, are precipitated by picric acid, bichloride of platinum, Valser's reagent, tannin, Bouchard's reagent, etc.—*Union Phar.*, March 15th. *Répert. de Phar.*, April 10th.

NEWS AND MISCELLANY.

BELGIAN ACADEMY OF MEDICINE.

The Belgian Academy of Medicine will celebrate its jubilee next December.

MANUFACTURED COFFEE.

Manufactured coffee can be detected by throwing the beans on some ether. Artificial coffee sinks to the bottom.

SANTONOLACTONE.

Santonolactone has been recommended as a substitute name for santonin, in order to avoid its being confounded with strychnine.

THE POPULATION OF FRANCE.

According to the last census the population of France was 38,095,150, including foreigners, which shows an increase of 208,584 over that of 1886.

TO WHITEN THE TEETH.

As a perfectly harmless, yet effective, agent for whitening discolored teeth, it is recommended to employ hydrogen peroxide made into a paste with prepared chalk or cuttle bone.

TO ABORT A BOIL.

The ointment of nitrate of mercury is said to be an excellent application in the case of a commencing boil or felon, its early use in most cases sufficing to prevent the formation of the furuncle.

GOOD ON FITS.

"I don't exactly understand the case, madame, but I'll tell you what I can do."

"O, what can you do, doctor?"

"I can throw the young one into fits, and I'm lightning on fits!"

"AN OUNCE OF PREVENTION, &c."

A folded periodical, of about this journal's size placed under the coat in the small of the back is said to be a sure preventive of pneumonia. Now is the time to subscribe. Copies ready for mailing, ten cents.—*Ex.*

STATUE OF GROSS.

The Treasury Department at Washington has decided that a statue of the late Professor Samuel D. Gross which will be erected in Washington by the American Surgical Association, shall be admitted free of duty.—*Ex.*

POLISH CONGRESS OF MEDICINE.

A Polish Congress of Natural Science and Medicine has just been opened at Cracow. It consists of more than a thousand members, including several distinguished scientific men from Warsaw, St. Petersburg and Geneva.

A CANCER PARASITE.

Dr. Russell, Senior Pathologist of the Edinburgh Royal Infirmary, has at length secured a cancer parasite and traced its life history. He finds it to be a fungus of the yeast type. Dr. Russell says the discovery can not be definitely accepted until tested by others.

LIQUID OXYGEN.

Professor Olszewski, of Cracow, recently succeeded in producing 200 grammes of oxygen in a liquid state. The experiment was made in the presence of numerous members of the Polish Naturalists' Congress, and the explanations given as to the qualities of the new fluid are said to have made a profound sensation.

CAMPHOR A SOLVENT FOR IODOFORM.

Camphor increases the solubility of iodoform in alcohol and ether. While one hundred parts of alcohol ordinarily dissolve not more than one and one-fourth parts of iodoform, the same amount of a saturated solution of camphor is capable of taking up as much as ten parts.—*American Practitioner and News.*

LACKAWANNA CO. MEDICAL SOCIETY.

The August meeting of the Lackawanna County Medical Society will be held on the 11th inst. at the Hotel Elmhurst at Elmhurst, a summer resort not far from Scranton on the D. L. & W. R. R. There will be a paper by Dr. M. J. Williams on the Intestinal Diseases Incident to the Heated Term, followed by a discussion. Dinner will be served at six, the members returning to Scranton at 9.05 p. m. An enjoyable time is expected and a cordial invitation given to all medical gentlemen to attend.

THE TEN COMMANDMENTS OF ABDOMINAL SURGERY.

1. The arrest of hæmorrhage.
2. The avoidance of mechanical irritation.
3. The guarding against infection.
4. The proper apposition of the edges of the wound.
5. The provision of necessary drainage.
6. To apply gentle pressure to prevent exudation.
7. To give perfect physiological rest.
8. To secure the best possible position of the parts to promote comfort and healing.
9. To provide for hygienic surroundings.
10. To attend to the patient's general health.—*Dr. Griffiths, So. Pract.*

THE CHOLERA AT KURNOOL.

It is curious as well as instructive, says the *Lancet*, to compare the number of cases and number of deaths in the town and district of Kurnool. In the town there were 140 people attacked, 57 per cent. of which ended fatally. In one place in the district there were 150 cases, and only forty-seven deaths—*i. e.*, 30 per cent. The explanation of this difference, people say, is to be found in the fact that while in Kurnool the natives would not, as a rule, take English medicines, in the district they were only too anxious to do so. This is the opposite of what most people would have expected, as townspeople are supposed to be better educated than the villagers.

THE HYGIENIC INSTITUTE OF BERLIN.

Since the retirement of Prof. Koch a year ago, this institution has been under the directorship of Dr. Erwin V. Esmarch, son of the Kiel Professor of Surgery. The appointment was, however, only a provisional one, and steps have been taken for a permanent appointment. A selection has at last been made in the person of Prof. Max. Rubner, of Marburg.who was brought up in the school of Karl Voit, of Munich. Prof. Rubner's career hitherto gives promise that he will not be an unworthy successor of the world-wide celebrity he follows. The new professor is 37 years of age, became Docent in Munich 1882, Professor Extraordinary in Marburg 1885, and Professor in Ordinary 1887.

MEDICO-CHIRURGICAL COLLEGE.

The following changes have been made in the Faculty:

Dr. G. E. Stubbs, Emeritus Prof. of Clinical Surgery.

Dr. W. S. Stewart, Emeritus Prof. of Obstetrics and Clinical Diseases of Women.

Dr. H. E. Goodman, Honorary Prof. of Surgery, Clinical Surgery and Orthopædics.

Dr. J. M. Anders, Prof. of Principles and Practice of Medicine, Clinical Medicine and Hygiene.

Dr. E. E. Montgomery, Prof. of Obstetrics and Gynæcology.

Dr. Ernest Laplace, Prof. of Surgery, Pathology and Clinical Surgery.

Dr. W. F. Waugh, Prof. of Clinical Medicine.

PHILADELPHIA'S POLYCLINIC.

ANOTHER IMPORTANT CHAIR FILLED BY THE BOARD OF TRUSTEES.

The Board of Trustees of the Philadelphia Polyclinic and College for Graduates in Medicine have created a third Chair of Diseases of the Eye, and, upon the unanimous nomination of the Faculty, have elected Prof. George de Schweinitz, M. D., to fill the position.

Dr. de Schweinitz is a graduate of the Medical Department of the University of Pennsylvania, class of 1881, and is at present Ophthalmic Surgeon to the Children's Hospital, Ophthalmologist to the Philadelphia Hospital and to the Orthopædic Hospital and Infirmary for Nervous Diseases, and Lecturer on Medical Ophthalmology in the University of Pennsylvania. He will be associated in his new field with Professors Edward Jackson, M. D., and S. D. Risley, M. D.

The new college announcement shows the teaching staff of this institution to be composed of emeritus professors, 4; professors 24; adjunct professors, 6; instructors, 6; lecturers, 4; clinical assistants, 23. Total, 67. The collegiate department is gradually acquiring apparatus for an elaborate teaching outfit, and that of the department of diseases of the mind and nervous system is at present unequalled, and the same may now be said of the eye department.

The Polyclinic Medical Society is accumulating an endowment fund for the establishment and maintenance of laboratories and the medical library, the nucleus of which has been placed in the hands of the Board of Trustees.—*Ledger.*

INTERNATIONAL CONGRESS OF THE RED CROSS.

The Red Cross Associations organized in

the European States which have signed the Geneva Convention have had the laudable custom of holding international meetings, at which the interests of the sick and wounded in war are practically considered, and the arrangements for a more effective and harmonious furtherance of those interests discussed and agreed upon. The first of these congresses was held in Paris in 1867, the second at Berlin in 1869, the third (*longo intervallo*) at Geneva in 1883, and the fourth at Carlsruhe in 1887. At this latter it was resolved that in future the congresses should meet every five years, the *locus in quo* of the succeeding congress being then undecided. The International Committee of Geneva has just proposed that the congress should hold its fifth meeting in Italy next year, and the Central Italian Committee, duly notified of the fact, has completed negotiations with the Government, according to which the seat of congress will be Rome, and April or May, 1892, the month in which it will assemble. Conformably with this arrangement, the President of the Italian Red Cross Association has already, in accord with the Geneva International Committee, sent off circulars to the central committees of the Red Cross Associations throughout Europe, inviting their presence and coöperation at Rome in April or May, 1892, the precise date to be subsequently fixed. In the invitations are also included the representatives of branch associations, so as to leave out no element which may conduce to the success of the Congress and of the important interests it has undertaken to promote.

NEW HOSPITAL AND CLINIC AT NEWPORT, VERMONT.

The village of Newport, Vt., is situated on the west side of a narrow neck of Lake Memphremagog, containing about three thousand inhabitants. West Derby is situated on the opposite side and contains nearly twenty-five hundred inhabitants. The locality seems to be a natural centre for all kinds of business and trade for many miles around. The physicians of both villages conceived the idea that the establishment of a Hospital and organization of a clinic would be a useful thing to do; that it would centralize practice, and be the means of retaining surgical cases at home for treatment, that now go away to Boston, Montreal, or Burlington, and thereby be the means of establishing a better reputation of the physicians at home.

On Wednesday, June 17th, the physicians of both villages met at the office of Dr. J. C. Rutherford, and organized a clinic, to be known as Memphremagog Hospital Clinic. Dr. J. C. Rutherford, of Newport, was chosen president, and Dr. C. V. Bogue, of West Derby, secretary. Clinics for the treatment of patients and for surgical operations were established on every Thursday afternoon at one o'clock. Each member of the clinic is required to be on duty as attending physician four weeks in succession, taking his turn alphabetically.

Patients are received at the Newport House, where the clinic is held, until a hospital building shall be furnished.

Dr. Bogue has recently operated successfully in one case of ovarion tumor. The case need not be reported in full; I will relate only some unusual features. The patient was 37 years of age; never had children; the tumor had been developing eleven years. When cut down upon it was found to have no adhesions. The patient made a good recovery notwithstanding she discharged large quantities of pus and blood in her urine during convalescence. Previous to the operation the urine contained albumin. The tumor was unilocular and weighed 13 pounds.

DIET AND ANIMAL TEMPERATURE.

A question has been put to us by a correspondent—Mr. Walter Fenton—whether the animal temperature of persons who subsist on a vegetable diet is lower than that in animal or mixed feeders. The inquiry has never been investigated in the human species on a sufficiently comprehensive scale to be of any value, but such comparative facts as throw light on the matter tend to indicate that vegetable feeders, amongst the lower creation, have a high temperature. Dr. John Davy, brother of Sir Humphry, and one of our keenest physiological observers of a past day, was amongst the first to make comparative observations of the temperature of different animals in their normal state; and to a certain extent John Hunter, Pallas, Despretz, and Samuel Metcalfe carried out the same research. In 1869 Dr. B. W. Richardson, in one of his lectures on Experimental and Practical Medicine, classified the results of most of these previous authors, and tested them by a new series of direct observations. His table of mean results showed that vegetable feeders have a high temperature. The sheep gave a temperature of 104°; the goat of 104°; the pigeon of 108°; and the com-

mon fowl 108°. The rabbit showed 103°, whilst the dog and the cat, animal or mixed feeders, showed 102°. But some herbivora were comparatively low; the ox, for example, 101, and the horse 100°. The differences here stated were supposed by the last-named observer to depend on the cutaneous covering of the animal more than on any other cause. In the case of the pigeon, on which this author made ninety-four observations, the high temperature was attributed to the non-conducting character of the feathers, a marvellous protection to a swift-flying animal in a cold atmosphere. In man, from 100 observations, he came to the conclusion that in a strictly natural state 98° F. was the truest standard. These researches are useful as comparative studies; still, it is an open question whether in man, or in any species of animal that can live on a mixed diet, there is a variation of temperature, according to mode of diet; and it would be a good work to inquire on a large scale if, under a purely vegetable form of dietary, the temperature in man is reduced. Our correspondent informs us that in him (a healthy man) and in his wife (a healthy woman), both in the prime of life, the temperature now ranges from 96° to 97.4° F. He for three years and a half, and she for two years and a half, have been total abstainers from alcohol, and have subsisted on fruit and vegetables, with addition of "butter, cheese, milk, eggs, and a little fish." Previously to adopting this system his temperature had never fallen under 98° "in so far as he remembers," and he therefore is inclined to the view that under his new regime he lives as healthily as before, at a lower expenditure of energy. If such prove to be correct, and if it should be demonstrated that a minimum animal diet (for our correspondent, be it observed, is not strictly a vegetarian) will support life efficiently under reduced combustion and reduced waste of material, a valuable as well as curious fact will be added to our practical knowledge. Evidently there is here open a fine field for a patient, perfectly unbiased, and truthful investigator.—*Lancet.*

THE PNEUMOGASTRIC NERVE.

Upon an average, twice a week,
When anguish clouds my brow,
My good physician friend I seek
To know "what ails me now,"
He taps me on the back and chest
And scans my tongue for bile,
And lays an ear against my breast
And listens there awhile.
Then is he ready to admit
That all he can observe
Is something wrong inside, to wit:
My pneumogastric nerve!

Now, when these Latin names within
Dyspeptic hulks like mine
Go wrong, a fellow should begin
To draw what's called the line.
It seems, however, that this same,
Which in my hulk abounds,
Is not, despite its awful name,
So fatal as it sounds.
Yet, of all torments known to me.
I'll say without reserve
There is no torment like to thee,
Thou pneumogastric nerve!

This subtle, envious nerve appears
To be a patient foe—
It waited nearly forty years
Its chance to lay me low;
Then like some blithering blast of hell,
It struck this guileless bard.
And in that evil hour I fell
Prodigious far and hard.
Alas! those things I dearly love—
Pies, puddings and preserves—
Are sure to rouse the vengeance of
All pneumogastric nerves!

Oh, that I could remodel man!
I'd end these cruel pains
By hitting on a different plan
From that which now obtains.
The stomach, greatly amplified,
Anon should occupy
The all of that domain inside
Where heart and lungs now lie.
But, first of all, I should depose
That diabolic curve
And author of my thousand woes,
The pneumogastric nerve!

—*Exchange.*

Clinical Lecture.

ON CERTAIN SEXUAL NEUROSES.

BY CHARLES L. DANA, M. D.,

PROFESSOR OF NERVOUS AND MENTAL DISEASES AT THE NEW YORK POST-GRADUATE SCHOOL, NEW YORK CITY.

ANATOMY AND PHYSIOLOGY.

The instinct of self-protection, the instinct of hunger, the instinct of re-production, these are the primary and compelling forces of animal life. Of these, the instinct of reproduction, as shown in the sexual function, is the most intermittent and shortest in duration, yet most intense in its activity, while it lasts.

The sexual function develops at the age of from 9 to 15 years, according to race or climate. In man it continues almost throughout life-time, sometimes even receiving a new impulse in old age.

The anatomical basis of the sexual function consists of a brain-centre, a spinal-centre, peripheral nerves and the sexual organs.

The *brain-centre* has not been exactly localized. Erection can be produced in dogs by irritating the cortex. Sexual feeling in many lower animals is closely associated with the sense of smell, and it is possible that the centre of sexual sensations in some domestic animals is in or near the limbic lobe, a lobe which lies on the median surface of the cerebral hemispheres, and identical in part with the gyrus fornicatus.

In savage and semi-civilized man sexual feelings were much more closely associated with olefaction than is the case in modern civilized society. In persons with degenerate brains or depraved instincts, gross illustrations of the relation of odor and sexual feeling are still seen. Krafft-Ebing cites the case of a man in whom erections were caused by the odor of flowers. Cardinal Richelieu is said to have been in the habit of stimulating voluptuous feelings by sitting in a richly perfumed room. Ordinarily, however, perfumes have but a remote sexual suggestion. This feeling is much more closely associated with visual images; more rarely by music, certain kinds of which produce voluptuous sensations. I have heard a patient confess that going to a certain Wagnerian opera caused feelings almost amounting to an orgasm. There is no definite cerebral "centre" for sexual feelings, however. They are most likely associated chiefly with the activity of the occipital and limbic lobes.

The cerebral centres are those in which arise voluptuous feelings and sexual desires. They also act upon the lower centres stimulating or inhibiting their activity. They have, therefore, a psychical and a mechanical side.

The *spinal centre* is situated in the lower part of the spinal cord and has the purely mechanical function that of controlling erection and ejaculation.

The *peripheral nerves* are the efferent or nervi-erigentes which are vaso-motor and motor, and the afferent which are partly nerves of cutaneous sensation and partly excito-reflex.

Erection—This is done by the afferent nerves to the blood vessels, which arise from the 1st to 3d sacral roots. Also by motor nerves to ischio-cavernous, bulbo-cavernous and part of transversus perinei muscles, arising from 3d to 4th sacral roots.

Ejaculation—This is done by efferent nerves to bulbo-cavernous muscles, arising from the 3d and 4th sacral roots.

The afferent sensory and excito-reflex nerves are the cutaneous nerves of the penis, running in the pudic nerve and arising from the 3d, 4th and 5th sacral roots.

The *genital centre* in the spinal cord extends from the 1st to the 4th sacral nerves, the erection centre being higher than the ejaculation centre.

Delivered at the Post-Graduate Medical School of New York.

The bladder and rectal centres overlap the genital, but are slightly lower than it, the bladder centre being the lowest.

The function of the peripheral organ in the male is to accomplish erection and ejaculation. The first is done partly by a relaxation of the muscular fibres of the corpora cavernosa and arterioles allowing the blood to flow in, and partly by the contraction of the bulbo-cavernous and ischio-cavernous, and deep part of transverse perineal muscles which constrict the root of the penis. The ejaculation of semen is the result of spasmodic contraction of the bulbo-cavernous muscle.

The sexual mechanism is closely connected with the vaso-motor nerves, so that the vaso-motor centre in the medulla may be looked upon as part of it. By irritating this as with asphyxiated blood or muscarin, erections may be caused.

The spinal centre is dominated by that in the brain. By an effort of the will voluptuous thoughts are inhibited or encouraged and the spinal centre correspondingly affected. Man alone possesses this inhibitory power and is distinguished from the brutes thereby. The spinal centre may be active when cut off entirely from the brain. Thus, in a case of total transverse destruction of the cord at the 12th dorsal vertebra operated upon here by Prof. Abbe, the patient had full erections and emissions, though entirely unconscious of them. The spinal centre developes earliest and erections may occur at the age of three or four years, while the cerebral centre and sexual feelings do not normally develop till the time of puberty. The cerebral centre, though developed late, often outlasts the spinal; and we see senile voluptuaries, spinally impotent yet indulging in all kinds of erotic excitements. These old men experience a sexual excitement which is purely cerebral.

We will turn now to the study of some of the disorders of the sexual functions. I wish first to show you on this chart the classification which is to guide us in our study.

You will understand that all those disorders which relate to cerebral centre so far as it is concerned with the sexual feelings and desires are called *psychoses*. Those disorders which are concerned with the lower centres and peripheral nerves, as well as with the more mechanical side of the cerebral centre are called *neuroses*. The distinction can not always be sharply drawn, but it is a convenient one.

CLASSIFICATION OF FUNCTIONAL SEXUAL DISORDERS.

The Sexual Psychoses are Divided into,

A—The Vicious Habits, such as masturbation, &c.

B—The Sexual Perversions, these are classed as

1. Masturbation, sexual murder and anthropophagy.
2. Flaggellation.
3. Exhibitionists.
4. Stercophily.
5. Contrary Sexual Instincts of which Pæderasty and Bestiality are examples.

C—Excessive Sexuality:—

1. Sexual precocity.
2. Senile sexuality.
3. Satyriasis.
4. Nymphomania.

Of the *sexual perversions* I shall say nothing except that they are happily as rare as they are disgusting, and are usually an evidence of mental deterioration. They are sometimes, however, acquired vices being the result of a continual search for new sexual stimuli on the part of voluptuaries.

Historians have asserted that several of the Cæsars were members of this latter class, so also was Louis XI and probably a good many other representatives of royalty in earlier days.

The Sexual Neuroses Are:

A—The Sensory Neuroses:
- Neuralgias.
- Parasthesias.
- Anæsthesias.
- Psychical Anæsthesia, (Loss of sexual desire).

B—The Motor Neuroses:
- Spasmodic—Nocturnal Pollutions.
- Paralytic—Spermatorrhœa.

C—The Secretory Neuroses:
- Polyspermia.
- Aspermia or Azoospermia, (Sterility).
- Prostatorrhœa.

D—Mixed Neuroses:
1. Impotence—viz:
   - *a.* From organic defects and diseases.
   - *b.* Psychical form.
   - *c.* Neurasthenic form.
   - *d.* Congenital defects.

Of the numerous and distressing array of maladies in the list here shown, the neurologist deals with but few, and these are:

Neuralgias.

Pollutions and Spermatorrhœa.

Impotence.

Masturbation and its various psychical results.

I propose to speak to you to-day only of the sexual psychosis, or vicious habit of masturbation and its most frequent consequence, seminal pollutions.

MASTURBATION AND POLLUTIONS.

Masturbation is the name given to the vicious habit of artificially exciting the sexual orgasm.

It is a very common vice in boys and less common but present in girls, and in adult men and women.

It is usually only a vice due originally to low associations and teachings among children. In some cases it is a disease or rather the symptom of a neurotic or insane constitution.

Ætiology—It is most common between the ages of 14 and 18, but may begin earlier. Even infants and very young children sometimes masturbate usually as the result of some local irritation which leads them to rub the genitals. Thus for example a tight prepuce, eczema or worms may lead to the practice; but it is usually taught by a companion. The practice sometimes attacks schools almost like an epidemic, for in every institution a certain per cent. of the boys are sexually precocious or vicious while the others are ignorant and innocent of the evils of the practice. Masturbation is relatively rare after twenty but is practiced throughout life even unto old age by some.

Results: Masturbation as ordinarily practiced leads after a time to a feeling of malaise, mental depression, disinclination to work, or study or enjoy one's self as before. The appetite is a little impaired, the extremities easily get cold, and perspire readily. Peculiar numb feelings are felt in the hands and feet. There is an unnatural nervousness and irritability, and the power of concentrating the mind is a little weakened. The patients often have dilated pupils and hyperæsthetic skin. After a time nocturnal emissions occur. The organs become irritable and slight excitement causes erections. These symptoms may be slightly marked and pass away in a day or two, or until another indulgence occurs.

Masturbation is sometimes done to an extraordinary extent, even daily or twice daily for a considerable time.

After a while the young man begins to find that he is not well, and realizes that this habit is hurting him. Then if he be sensible and of healthy constitution he stops. Others are frightened out of it by friends or by reading the terrorizing stories printed in quack advertisements and circulars. Sometimes the fright thus caused leads the unhappy youth into a condition of hypochondriasis, which is helped on by the occurrence of nocturnal pollutions and the nervous debility resulting from his past indiscretions. In other cases in which there is a decided neurotic history, a genuine neurosis which is called sexual neurasthenia develops and annoys the patient for years.

Masturbation rarely leads to insanity and is oftener a symptom than a cause of such disorder.

It is occasionally the cause of epilepsy. When this is the case the convulsive attacks are likely to put on a peculiar hysteroid phase, they are accompanied with peculiar co-ordinated convulsions and emotional disturbance.

Case I. The patient whom I have just shown you illustrates a very common phase of the trouble. He is a boy of sixteen, who belongs to a somewhat neurotic family. He has been carefully brought up, and has had no nervous disorders. Two years ago he learned the habit of self-abuse, and has since practiced it weekly and sometimes daily. A few months ago his parents noticed that he was more irritable, lost interest in his studies, looked pale, slept badly, and became somewhat thinner. Inquiry revealed the source of the trouble, and also that he was having one or two nocturnal emissions weekly. The boy was badly frightened about himself. He was placed on bromides, taken from school, and kept at work out doors. But his emissions continued. I saw him a month ago, and prescribed atropia and bromides, twice a day, noon and night, with a drachm of fluid extract of salix nigra at night. Besides this, cold steel sounds were introduced into the urethra for ten minutes, three times weekly. He was made to take cold sponge baths daily, and was given an impressive lecture on the necessity of stopping his bad habits. He is very much better now, and on the high road to recovery.

AUTOMATIC MASTURBATION.

In some cases masturbation is done automatically in the sleep, and then very stringent measures are needed to overcome the practice.

Case II. A boy aged fourteen, of a very neurotic family, had suffered for over two years from chronic chorea and incontinence

of urine. The bladder would empty itself in the day time as well as at night, so that he had to wear napkins constantly. I suspected masturbation, and it was confessed to me. The practice was stopped. The enuresis during the daytime then ceased also, but it continued at night, and was not in the least controlled by belladonna, ergot, bromides, rhus or other remedies. A brother who slept with him told me that the boy made peculiar convulsive movements of the legs during sleep, and I suspected involuntary masturbation. I contrived a splint by which his legs were kept apart and immovable. He wore it and his enuresis ceased. His chorea also gradually disappeared.

Case III. A still more obstinate case was that of a single man, aged 28, who suffered from the neurasthenia of adolescence, and who had nocturnal pollutions. He would awake and find himself in the act of masturbating, and there was no doubt that the pollutions were the result of this involuntary process. He made a number of ingenious attempts to stop it. He tied his hands behind him; but worked himself loose in his sleep. He then tied his hands to the bed posts above his head. This answered for a time, but again he succeeded in untying the knots and getting free.

Finally I put him in the masturbation drawers, devised by my colleague, Prof. Graeme M. Hammond. These consist of strong canvas drawers, fastened about the waist with steel bands, the side of which are padlocked. The patient locked himself in the drawers every night, hid the key, and his pollutions ceased.

Prognosis. The habit never causes serious disease in persons of originally healthy nervous stock. In neurotic persons it leads in some cases to sexual hypochondriasis and neurasthenia with nocturnal pollutions, and this is its commonest evil result.

Much more rarely it excites epilepsy and insanity. The old views that masturbation is a frequent cause of insanity are not now entertained.

The extraordinary impunity with which some persons masturbate, is illustrated by the patient whom I have shown the class recently as a case of sexual neurasthenia.

Case IV. The man is a peddler, married, and forty years old. He began masturbating at the age of sixteen, and has continued almost daily ever since, *i. e.* for twenty-five years. Even marriage did not cause him to desist, for he experiences greater pleasure in self-abuse than in natural indulgences. The result is less than might be expected for he is alive and sane, which is indeed surprising. But he suffers now from, sexual weakness, neurasthenia, dyspepsia, and a long train of subjective symptoms. The fact that he has masturbated so much and preferred it to sexual indulgence, is evidence of a congenital perversion of the sexual function. For though we can not explain the reason, it is certain that in normal individuals, masturbation is a depressing, and more or less injurious act, while the normal sexual act is not.

Diagnosis. Many victims of the masturbation habit, who have come to recognize its evils and tried to stop it, develop as I have said a hypochondriacal condition, and feel sure that there is something in their faces, which reveals to the world their trouble. This is not the case. But there is a certain physiognomy, which in a measure, characterizes the masturbator to such an extent that an experienced observer can detect it. The pale, pasty complexion, moist furtive eye, dilated pupil, listless, restless, and depressed manner, the wet flabby palms, hyperæsthetic skin, all help to tell the story. Locally the penis is often reddened and more or less turgid, the scrotum relaxed, and a variocele may be present.

Examination of the urine may reveal spermatozoa. The urine also is almost always of rather low specific gravity, and contains a great excess of phosphates, both earthy and alkaline.

The Treatment: Moral, Hygienic, Local and Medicinal.

The patient must be told plainly the necessity of stopping the practice. He must be impressed, but not terrorized. He should be kept out of doors at vigorous physical exercise; for sedentary and solitary work is always bad for such cases. He should be made to take cold water baths. He should sleep on a hard bed with light covering, and he had better sleep with some one whose presence may exercise a controlling influence. He should not eat heartily at night, never just before going to bed and what is still more important he should not drink before going to bed. Sometimes it is well to have him wakened at an early hour in the morning, when he should empty his bladder. For emissions occur often early in the morning and are promoted by the irritation of a full bladder.

Locally cold steel sounds may be introduced, and allowed to remain for ten minutes, three or more times a week. Or

the psychophor or Ultzman's short catheter may be used. In bad cases with a great deal of prostatic irritation, local applications of nitrate of silver are needed. Internally, a mixture of Tinct. opii Mv, Tr. camph. Mx, and Tinct. lupulin. Mxxx, may be given at night, the ingredients being somewhat varied in amount to suit the case. I once gave this mixture to a sailor, who like most sailors masturbated and suffered from pollutions. It cured him, and he gave some to the captain who prescribed it to the mates, and before the voyage was over, the whole crew were rejoicing in the efficacy of the combination.

Bromides, chloral, atropia, and salix nigra are also drugs which are often useful.

The mechanical measures which have been devised for preventing erections, such as rings with sharp teeth, are rarely needed and rarely useful. They may even do harm by directing the mind to the affected function.

I do not believe it right for the physician to prescribe fornication. It is not safe nor curative, apart from the moral aspect of the matter.

It has always struck me also as pretty small business for a man to purposely select a wife to relieve him of the results of a weak will and vicious sensual indulgence. If marriage comes in the natural course of events as it often does, so much the better. But to select a wife as a remedial agent for masturbation is unjust to the woman and a confession of moral and mental feebleness.

Man is distinguished from the brute by his self-control. Let him bear this fact in mind and raise himself above the animals by a determined effort of the will. Pure thoughts, and chaste associations, vigorous physical exercise and a resolute effort to act a manly part will always be successful.

COMMUNICATIONS.

A FEW NOTES, DIDACTIC AND CLINICAL ON OSTEO-GENESIS AND OSTEO-PLASTY. *

BY THOMAS H. MANLEY, M. D.,

VISITING SURGEON TO THE HARLEM HOSPITAL, NEW YORK.

Modern research and experimentation with the application of facilities which recent discoveries have placed in our hands, have given an immense impetus to the study and utilization of surgical osteogenesis.

This term, in this instance, is restricted to that process, inherent, in healthy bone and its investments, which is called into action, in that class of cases, in which, through surgical intervention the osseous structures are directly dealt with.

Anæsthetics have made it possible to now successfully encompass manipulation of bone substance, which always entails considerable consumption of time. Hæmorrhage may be easily controlled and the operating field efficiently cleared of accumulations of blood and coagula, which obscure the normal arrangements of the parts. Intelligent antiseptic methods eliminate the danger of infection.

Surgeons, pathologists and physiologists, have, for ages, been occupied in the study of regenerative osteogenesis and even until our own day, there is no unanimity of opinion among our ablest authors, on the question of the share which the periosteal envelope, the medulla or adjacent parts, contribute towards the protection of callus and solidification of bone. That there should be so wide a divergence of opinion among those accustomed to precise and exact scientific observation, is difficult to explain.

It is generally conceded that under ordinary circumstances the periosteum plays an important part, but that it is the sole agent, in bone reproduction has been denied.

It is important, however, before anything definitely can be undertaken, that some middle ground be reached and so have positive evidence of the divers functions of the fibrous membrane, that we may be acquainted with the various lesions in which it seems to be the sole regenerator and those in which it serves but a subsidiary part.

The periosteum is a thin, fibrous membrane which envelops and nourishes the bones. Histologically identical in composition and arrangement with ordinary thin, fibrous aponeuotic plates of tissue, its minute elements have no characteristic relations to each other, and the precise manner, in which its osteoplastic layer elaborates bone corpuscles is yet very imperfectly understood.

The bones are everywhere invested by this membrane, except where they are covered by cartilage at their articular ends. The muscles and their tendons, nearly all, arise from or are inserted into this membrane. In youth, when its regenerative power is greatest, it is thick and very vascular.

The bones of the skull are lined by separ-

* Read before the Metropolitan Medical Association of New York, June 10th, 1891.

ate layers of this membrane; the external being very delicate, but beneath the muscles is intimately adherent to the outer plate of the skull by numerous prolongations from its under surface, which penetrate deeply into the superficial lamellæ of bone.

Its osteogenetic powers are most active in early life and continues until the age of thirty or thirty-five, at which time it yet acts with energy, in elaborating ossific material in fracture, and retains this power until the end of life, to a certain degree, but after thirty-five it is incompetent to restore the loss made by a resected segment of bone.

The skeleton taken as a whole, in early life, owing to the preponderance of organic elements present, is pliant, elastic and vascular; but when middle life is reached, the diaphyses and epiphyses of the long bones have consolidated and the osteo-chondral structures have completely ossified.

The bones now have become more compact and brittle; hence are more liable to complete fracture and tardy repair.

The role of the bone marrow, as a factor in the regenerative process, has not yet been fully determined.

Nerve filaments ramify freely through the periosteum and penetrate the bone. It has recently been demonstrated that the lympatic vessels pierce the lamellæ of the compact substance and are numerous in the cancellous tissue of the articular ends. The healthy bone is everywhere very vascular and when fractured gives rise to a free extravasate.

(*a*) Although the various bones of the body possess physiological and anatomical features common to all, still clinically there is a wide difference in the nature and degree of their regenerative power when they have sustained a lesion of continuity.

(*b*) Manifold and complex are the conditions which favorably or unfavorably influence restorative osteogenesis.

(*c*) Besides, the various anatomical structures and histological elements, each manifest definite and characteristic peculiarities when the seat of pathological processes.

(*d*) The bones of different individuals otherwise healthy, vary greatly in fagility, and in propensity to unite, after fracture.

The failure of securing prompt union, without shortening, may be often readily accounted for by recourse to physics. With a bone as the femur, imbedded and acted upon, by powerful sets of muscles, to retain the broken ends in opposition, in fracture, without unbearable pain to the patient; danger of extensive excoriations and sloughing of the soft parts, is sometimes an almost insurmountable difficulty.

This trouble, in immobilization of the humerus is not encountered, yet it unites with difficulty. The bones of the forearm will, as a rule, unite much more quickly than those of the leg. The broken rib, which is in constant motion, will unite in a week, while a fracture of the inferior maxilla, which can be readjusted and fixed only with great difficulty, readily consolidates.

Fixation and immobilization of the fragments are indispensable in a general way, though, I have several times found, in cases of ununited fractures of the tibia that by removing the splints, retaining the simple bandage and putting the patient on crutches, motion rapidly ceased, at the point of fracture, and the full functions of the limb were quickly restored. Age, climate, season, diet, conditions of health and these species of fracture, all make their impress on the regenerative processes of bone.

There is never anything like full restoration of normal function in a limb, fractured after the meridian of life is reached. In very cold climates and in the frigid season of a temperate climate, it is a well-kown fact that union of a fractured bone is somewhat protracted. Among inmates of penal or pauper institutions, with the maimed after battle in times of war, badly housed and poorly fed, fractures fare very badly.

My experience has been that fractures in women, as a rule, do badly. They seem to occasion more pain and require a much longer time to firmly consolidate. This is notoriously the case in suckling and pregnant women.

Finally, there is a class morbidly prone to fracture. Many cases have come under my observation who have either simultaneously or consecutively fractured the same bones of both limbs, by moderate force. There are two cases now under my care—one a man of fifty, and a woman of fifty-five—with one the fall was but 10 feet, with the other, she simply stumbled. Both had double Colles. The point of fracture being in the same identical part of the radius.

Several cases have come under our observation of consecutive fracture, first of one bone, then at some time later, the same bone on the other side of the body. This is very commonly the case with the patella. So frequently has this consecutive fracturing, particularly of the lower end of the radius, occurred in my experience that just now when so many are ready to commence civil action

for damages, I make it an invariable custom to examine the opposite limb, so that should occasion arise, evidence may be submitted that the limb was normally wanting in firmness and strength.

The bone, anatomically, besides the periosteum is composed of other structures, which separately and collectively, possess singular and unique peculiarities; with which it is important, that at least, we should have a passing acquaintance; before we proceed to the study of practical osteoplasty.

Every bone of the human body except those forming cavities; as the orbital plate of the frontal; the os unguis, the palate vomer and turbinated and the ossicula auditus, are composed essentially of two substances, the compact and the cancellous. The flat bones are formed of two plates, between which is lodged, the cancellous tissue or the diplœ.

The irregular bones are composed mainly of spongy, osseous material, enclosed within a layer of compact tissue.

In the shafts of bones, compact tissue preponderates, while their articular ends are composed mainly of cancellous material.

As we might expect, when their is loss of substance in the shaft, which is enveloped by the periostum regeneration is more prompt and complete, than at the epiphyseal extremities, where this membrane is wanting.

The various elements of bone present a marked difference in their susceptibility to traumatic and pathological influences, in various stages of life, and in certain diseases.

In early childhood, peripheral or parenchymatous changes of the solid structures most frequently occur, as a result of injury, or of tubercular invasion; while in injured adults or those, the victims of constitutional syphilis, the periostial investment is almost invariably, the seat of primary pathological changes. In cancerous disease, destructive changes, indiscriminately spread through the osseous structures, with no marked predilection for any special histological element. It is interesting to note, that in sarcoma of young children when it develops in long shafts, its most frequent original nidus is in the medullary membrane; in close proximity to the distal, epiphyseal line.

The healthy bone taken as a whole, although tolerant of great pressure and concussive force, yet, when exposed to the atmosphere, rough manipulation, very hot or cold liquids, or irritating, antiseptic solutions, is extremely susceptible to irritation, which may terminate in acute or chronic inflammatory changes, that will give rise to very serious molecular transformations.

Hence, the explanation often, for consecutive periostitis, osteitis and osteo-myelitis; the reason why, not infrequently, after antiseptic amputations, with primary union, we so often see, recently, shapely, but irritable stumps, which can endure little, if any pressure and will possibly demand ultimately, consecutive resection.

Nails, ivory pegs, or wire are usually well borne in the cancellous parts, as in resection of the knee-joint, and serve a useful purpose, as accessories to fixation; but as a rule, the compact shafts of bone, violently resent their presence. It is claimed here, that a myelitis is first excited, and thence, by propagation extends into the lacunæ and canals of Havers. I have often observed when the shafts are wired, that there is usually a rapid and extensive suppuration of the overlying, soft parts, regardless of what antiseptic precautions may have been taken.

The diversity of tolerence. in the diaphyseal and ephyseal structures of the bones, will account for the surgeon's chariness, in dealing with fractured shafts of bone, particularly the femur which when fractured, in our time, one would think, by making a simple, compound fracture, the ends might be readily wired or pegged and all future shortening, wholly obviated, without imperilling life.

OSTEOPLASTY AND OSTEO-PLASTIC OPERATIONS.

Osteoplasty consists in such precedures as may be adopted by the surgeon, for injury, deformity, destruction or disease of any part of the osseous system, which are attended with division of the subjacent, or overlying soft parts.

Osteoplastic operations in general, after the scheme of M. Ollier, (Traite experimental et clinique de la Regeneration Des Os), may be divided into three classes, viz: homoœplastic, autoplastic and retoro-plastic; i. e. those in which, 1st. A displaced fragment of bone may be replaced from where it formerly came. 2nd. Those in which osseous tissue is transplanted from one region of the same body to the other; 3rd. Those cases in which bone is taken from one animal and inserted into the tissues of another species.

Ollier declares, very emphatically, after a very long, and most exacting series of experiments and clinical observations, that the two former, only, are at all practicable in surgery, and that any attempt at securing a permanent, durable consolidation by

attempting to engraft the elements of bone from the lower animal to man, must end, inevitably, in failure.

This does not imply, that one cannot insert a fresh fragment of bone, from the animal to man without exciting suppuration, or giving rise to serious disturbances; for one can do this with a piece of cork, metal or wood; but the successful, heterogenous transference of bone element is denied.

Many cases of success have been reported by zealous but indiscreet investigators, who, however, later were compelled to admit failure of assimilation; ultimately the foreign tissue, either giving rise to local ulceration, or undergoing digestion and absorption, through the action of the blood vessel and lymphatics.

The artificial tamponing or packing of bone cavities with decalcified, animal bone chips should scarce come under this category of heterogenous, osteoplastic procedures; as the analogy between this undertaking and the practice of transferring vital tissues, is rather strained and scarcely admissable. In this instance, we are dealing with dead bone; it having been subjected for days, to the macerating action of powerful acids, in dissolving out the lime salts; so that, physically and chemically there is no more comparison between this dry, limeless substance and the living vascular bone, than there is between the normal integament of an animal and the same, when it is transformed into leather. What share a large blood effusive serves, in the way of accellerating or retarding union, at the seat of a fracture, is yet, an mooted question; some alleging that it favors consolidation by undergoing osseous changes, while others regard its presence as an irriant; rather delaying regenerative changes. Latterly, it is said, by some, that when a bone cavity is filled, with aseptic blood and covered in by antiseptic dressings, it will undergo osseous changes and permanently assimilate itself, with the walls of the bone, which enclose it. That a blood-clot will undergo fibrous organization in the healthy subject, has been long known; but that it as a blood clot can take on primary, osseous changes, transforming itself from a fluid into bone, is not in accordance with pathological laws, or those governing regenerative processes.

Autoplastic and homœoplastic operations will, undoubtedly, hereafter play an important role in the surgery of the bones, pathological and traumatic. My own observations in osteoplastic procedures, have been so auspicious, as to induce me, to take such a bold and aggressive attitude, in connection with their application, in disorganizing traumatisms of the limbs; that under no circumstances, whatever, in civil life, do I believe we are now justified, in the performance of an immediate amputation; but, that resection should be always substituted for primary amputation. (Resection as a Substitute for Primary Amputation. *New England Medical Monthly,* July, 1891. By T. H. Manley, M. D.)

As will be seen in my brochure on this subject, that it is maintained, there-in that unless the force itself, at the time of accident, so crushes the limb—amputates it in fact—that it only hangs by a few tendonous shreds, which may be snipped away with the scissors, it should not be disturbed by any instrumental intervention whatever. The intelligent and conservative utilization of osteoplasty, conjoined with antiseptic methods must wholly revolutionize this domain of bone surgery. Hence, measures and methods, which, in their time, had much to commend them, must now be swept aside as antiquated; to make way for the latest innovations, which modern science has placed in our hands, and which we know, by a thorough and extended testing are so far unrivalled in their results.

No longer, will we see the deformity and helplessness, resulting from an irreduceable dislocation, while tenotomy, arthrotomy and ostectomy are so safely and rapidly performed. Certain varieties of paralysis, deformities and atrophies may now be largely obviated, or promptly rendered by a surgical therapy, which heretofore, was attended with imminent peril, both to the limb and even life itself.

It is immaterial whether osseous deformities are congenital or acquired; pathological or traumatic modern measures are equally applicable to all. Nor should we hesitate, because of extremes of age; for, my own results, in osteoclasis or osteoplastic operations on the new-born, in uranoplastic and hare-lip operations, performed, as soon as possible after birth—in three cases, on the second day of life—have been most satisfactory and such as could not have been realized, after advanced ossification was effected.

Homœoplastic operations have a wide range of application, and when performed with a clear idea of what it really is; with a rigid observance of detail and subsequent treatment, the results are all that can be desired.

Every compound fracture; single or

multiple, should usually now be treated, by a homœoplastic method, *i. e.* the displaced ends, or segments of living bones, with the muscular or connective tissue remaining in tact, and an ample blood supply, are brought into opposition, fixed and covered.

Now, these conditions must obtain in every instance, or else, what we do, is not an homœoplastic operation; as the fundamental requirements in any case; are, that the displaced bones have a vascular connection. The more extensive this connection, the less necrosis of the replaced fragments, and the more rapid and complete the cure. This I have verified on many occasions. It was immaterial of what shape or extent the displaced fragment, provided, it had a good grip on the adjacent tissues, it usually took on vitality and assimulated with the bone tissues, from whence it came.

I have never seen a fragment of bone which was wholly detached from a shaft after replacement, take on vitality. These operations failed every time, regardless of conditions.

The importance of bearing this fact in mind, cannot well be over estimated. Just now, when one might be lead to suppose that detached bone will consolidate, as claimed by many late observers. Now, one must not confound the imbedding of an aseptic fragment of bone; as may be done with a tooth, for the genuine ideal restitution of a living fragment, which is capable of regenerating itself.

Among the former, belong to that class of cases of cranial surgery, wherein, fragments or discs of chiselled or trephined bone, after having been removed, for a variable period of time, are replaced and an alleged re-ossificative of bone is effected so that the portal or chasm is filled in.

There can be no question, but when a button of osseous tissue is removed from the skull, it may, after replacement, acquire a more or less firm adhesion; but is no longer a substance, endowed with life and is at best, a foreign body; an incapsulation of it, is mistaken for assimilation and restitution. That this must be the case is evident to any one who will investigate into it precisely, what has been expected. First, the bone is *completely* cut away from the skull. Secondly, it is placed, in an antiseptic liquid, where it remains until it is restored, to fill in the gap, which it occasioned.

The antiseptic fluid simply presents septic infection and nothing more. It does not preserve its vitality; rather, by its permeating, irritant action on the endothelial lining of its reticular, vascular thickness, it thoroughly destroys it. Neither does it interfere with chemical or molecular changes; but on the other hand, by the free chlorine which is liberated, acting on the lime salts of the bone, it accelerates it. Once wholly freed from its vascular and neural structures, physiologically, "bone is no longer bone." This applies to the osseous structures, wherever situated.

Autoplastic operations comprize that class, wherein, we transfer a section of bone from one region to the other, in the same body. It has but a very limited application in the human body, and is employed almost solely, for the purpose of overcoming deformities; as when the nose has been destroyed and we essay to restore it; or construct a substitute. To ensure success in this procedure, the soft parts must be carried along with the bone *en masse* and firmly secured, until the graft has formed firm adhesions and attained an independent existence. Its technique is extremely difficult and complicated; trying to the surgeon; and, without resolution, with more than ordinary fortitude on the part of the patient, is utterly impracticable. Yet, autoplasty constitutes a valuable resource in proper cases, and should be ranked as one of the most important achievements of modern surgery.

Periosteal or heterotopic osteoplasty, consists in the transplantation of periosteal grafts from the shaft of the healthy bones, and sewing them into the tissues, where they are to be utilized as bone, when they have taken in osseous changes and development.

The periosteum being carefully dissected from one side of the convexity of the shaft, is transplanted into the loose cellular tissues, among which, it contracts adhesions and in a comparatively short time, undergoes in its new site, complete osseous transformation; a firm, thick plapue of bone forming within a very short space of time. This procedure has been utilized with great advantage in certain cases attended with loss of bone.

When the priosteum is removed in small sections, no harm will result to the denuded bones; as that part of the membrane remaining, is ample to maintain nutrition and prevent exfoliation.

The object in view, in all osteoplastic operations are to repair, preserve, and utilize bone substance. To give solidity shape, contour and durability to a part. This class of operation is based on extreme

concervation, and requires for its successful attainment, not only the most minute attention to technique and a discriminating judgment, but patience and perseverance as well. As life is not jeopardized, when reasonable precaution is exercised, we are the more justified in always commending a surgical resource, which will usually make no serious impress on vital processes.

There seems little more to learn, in relation to osteogenetic function, but there yet remains, a large field, in which to practically apply the knowledge of it, in our possession. That osteoplastic operation, which will result in the saving of thousands of limbs and joints which has heretofore, been sacrificed; prolong and render life more tolerable, has been incontestably proven.

With this invaluable acquisition in our possession, and our facilities for preserving limbs, heretofore sacrificed our obligations and responsibilities have been greatly augmented.

CHRONIC INGUINAL ADENITIS.

BY H. F. SLIFER, M. D.,

NORTH WALES, PA.

A boy four years of age, with a good history, and healthy parentage, began to fail in general health, during the summer of 1888. He complained of feeling weak, was listless and exceedingly pallid, with loss of appetite, and emaciation without any apparent cause.

This condition continued until November when he began to have pain in the right leg when walking long distances, this gradually grew worse, until it became intense, during the night if he attempted to turn or move the body, he would cry out with pain. His suffering appeared to emanate from the inside of the thigh. Pressure below Poupart's ligament over the pectineal fascia would produce pain, moving the leg was not painful, nor was motion impaired.

At this time no swelling could be detected, both limbs being alike in size and general appearance. After two months had elapsed, the pain in a degree abated. A slight fulness at the upper portion of the pectineal fascia now manifested itself, tender on pressure, but no elevation of temperature nor alteration in the hue of the skin.

One month later, the thigh began swelling at the upper part, which gradually continued down the limb, until the entire thigh was involved, the circumference being $1\frac{3}{4}$ inches greater than that of the opposite side; at no time did it extend beyond the knee.

The original swelling in the groin now increased to a considerable size, forming a tumor below Poupart's ligament and inside of the saphenous opening, two inches in its perpendicular diameter, due to induration of the inguinal glands; this enlargement presented firm resistance to pressure, was tender but not painful, no heat in the parts, nor constitutional fever.

The boy's general health was very much impaired, the appetite remained poor in spite of tonic treatment. He continued pale and emaciated to an alarming extent. I could ascertain no cause for this condition, other than lymphatic disease, confined chiefly to the inguinal glands, although the cervical glands were enlarged at times, but only for a short duration.

The most interesting feature of this case, was its obscure symptoms in the early stage of the disease.

The difficulty in arriving at a proper diagnosis arose from the fact that no local manifestation existed, except pain in the leg, and slight lameness at times, and failure of general health. The nature of the disease, however, became very evident, later on in its course.

A prominent physician, regarded the case one of incipient hip disease, and recommended rest in bed. This opinion was not in accordance with my view of the case. I objected to this procedure, on account of his debilitated condition, and his need of out door air and exercise.

Dr. John B. Deaver, of Philadelphia, saw the boy with me, and after a thorough examination, endorsed the diagnosis of chronic inguinal adenitis.

The pathology of the lymphatic glands is frequently overlooked in children, and its importance under-estimated. The early recognition of this condition may avert serious consequences. The profound anæmia attending these cases reveals a morbid constitution. It is evident that the nutritive functions are disturbed, absorption impeded, and the blood forming organs diseased.

The inflammation may be limited or it may extend to more distant glands. From the glands the disease may be conveyed along the connecting branches, to the deeper set of vessels, and the inflammation may also extend through the intervening tissue. Inflammation of the lymphatic vessels show a tendency to extend to the connective tissue, cellulits is, therefore, almost a constant accompaniment.

Hyperplasia of the cervical glands is common, resulting from eczema of the scalp or face, or from otitis, or any of the forms of stomatitis; the irritation is conducted to the glands through the lymphatic vessels. The same is true of the mesentric, axillary and inguinal glands. The slightest traumatism or irritation, such as solar rays, and friction of clothing, and sting of an insect, or pressure of a shoe, may set up superficial inflammatian, the toxic products of which are absorbed and conveyed to the glands.

Morbid changes in the lymphatics are frequently observed in children whose food is not sufficiently nutritive, or the digestive powers feeble. Children who have been prematurely weaned, and who have been given food that is not adapted to their age. Indeed, any condition interfering with the healthy state of the mucus membrane, or a break in the continuity of tissue anywhere, may permit the invasion of microbes and give rise to adenitis.

The usual termination of chornic adenitis is fibrous induration, caseous or scrofulous degeneration, amyloid degeneration and calcarious infiltration. The fibrous induration is common in the inguinal glands, and is frequently met with in this region without any morbid symptoms, as illustrated in the above case, exhibiting a chronic character from the beginning, and recovering without suppuration or degeneration.

The treatment was conducted on general principles. Directing special attention to his nutrition, proper diet and outdoor exercise. Administering from time to time, such agents as iodide of iron, iodide of potassium, syrup hypophosphites, elixir quinine, iron and strychnia, pepsin, etc. To the glandular induration I applied tincture iodine, mercurial ointment and ext. belladonna, with friction, and ordered the thigh bandaged. Under this treatment the boy gradually improved, but did not fully recover until Feb. 1890. At the present time he is enjoying perfect health.

THE DANGERS OF LEAVING THE PRODUCTS OF INFLAMMATION IN THE FEMALE PELVIS.*

BY CHAS. P. NOBLE, M. D.,

PHILADELPHIA.

The term, product of inflammation, in this paper, will include the various morbid conditions which result primarily or secondarily from pelvic inflammation.

The conditions which come properly under our title are salpingitis, including pyosalpinx, hydrosalpinx, hæmatosalpinx, catarrhal salpingitis with adhesions and without adhesions, ovaritis, including ovarian abscess, intraperitoneal inflammatory exudate, and cellulitis and pelvic abscess. Manifestly the danger to life from these conditions varies widely, and to avoid confusion it will be neccessary to consider them in detail.

The natural history of pyosalpinx is now well known, and the natural termination of the disease is the death of the patient by peritonitis; exceptionally by superinduced general diseases, such as phthisis or Bright's disease. I consider that the foregoing statement requires no support, because evidence upon this point is so demonstrative as to put it beyond dispute. At the same time it is admitted that, as an exceptional occurrence, a pyosalpinx will discharge itself through the uterus, or through the bowel or elsewhere, and a so-called "natural cure" take place. Or, as in other regions of the body, it is possible that the pus may become caseous, and the progress of the disease be arrested. In neither case, however, has a cure resulted—a crippled, occluded, painful, useless appendage remains to torment its possessor. Undoubtedly, then, while a single or double pyosalpinx remains in the pelvis, the danger to be apprehended is invalidism and death. Recurring attacks of peritonitis, any one of which may prove fatal, and gradual failure of the vital powers are only to be prevented by the removal of the diseased organ or organs.

All that has been said of pyosalpinx is even more true of abscess of the ovary, which, generally speaking, runs its course to death much more rapidly. Especially is this true of the puerperal variety.

These conditions result from salpingitis. Both are usually bilateral. Why the occluded tube at one time fills with pus, at another with serum and at another with blood, is an interesting problem yet to be solved. Supposedly it is due to the nature of the infection. Perhaps the occurrence of hæmorrhage into the tube is accidental. (No reference is made to hæmatosalpinx due to congenital or acquired atresia of the uterus or vagina.) While hydrosalpinx and hæmatosalpinx differ, they are alike that in both cases the tube is permanently occluded, at least at its fimbriated end, and, therefore, functionally useless. Hydrosalpinx is essentially a chronic disease, having an indefinite

*Read before the Philadelphia Obstetrical Society.

natural termination. Indeed, it has been argued that hydrosalpinx is a natural cure of salpingitis; to this view it is unnecessary to say that I do not subscribe. The history of hydrosalpinx is characterized by recurring attacks of peritonitis. The danger to life in such attacks is distinctly less than when the cause is pyosalpinx. The fluid contents of the tube are not necessarily septic. At times the uterine end of the tube becomes patulous, the result being the *hydros tubæ profluens* of the older authors. In this way the condition may be relieved, but a useless appendage is left. I have found hydrosalpinx, as a rule, in women in the thirties or forties, who have been invalids for years. Judging from my own experience a fatal termination must be rare; but invalidism has been constant. The effect produced by the menopause upon hydrosalpinx is unsettled. What has been said of hydrosalpinx is largely true of hæmatosalpinx. The fluid, however, is distinctly more septic. Hence the danger to life is distinctly greater. Both hydrosalpinx and hæmatosalpinx permanently destroy the function of the tubes; they produce invalidism by recurrences of peritonitis, and at times death.

This condition may be unilateral or bilateral. It entails suffering rather than endangers life. It is plain that salpingitis with adhesions becomes pyosalpinx, hæmatosalpinx or hydrosalpinx, if, through recurring attacks of inflammation, or through a progress of the catarrh, accumulation of the inflammatory products occur. It is in this way that the condition in question may endanger life. On the one hand the condition may become worse at any time; on the other it is more than questionable if it gets well. Provided the adhesions have occluded the fimbriated extremity, it is a permanently crippled, functionally useless tube. A woman having two occluded tubes must be permanently sterile, unless it be admitted that a tube once occluded by inflammatory exudate can become patulous. Removal of such organs is justified on the ground the they are useless, that their presence entails suffering, and may threaten life at any time through progress of the salpingitis.

At times salpingitis occurs and the tube remains patulous. This may be true even when the tube is bound down by old peritonitis. This class of cases is a most important one. The disease may progress from bad to worse; but this is not the only danger. This is the condition which causes tubal pregnancies, which is an ever-present danger. This condition of the tube often exists on one side, with graver disease, as pyosalpinx, on the other side. Salpingitis with a patulous tube does not endanger life in itself, but may by occasioning tubal pregnancy, or by becoming progressive.

It must not be forgotten that a healthy tube may be present on one side and a diseased tube on the other; thus uterine pregnancy may occur. It is probable, also, that uterine pregnancy may occur where one tube is patulous, even if slight catarrh is present. These considerations render plain supposed remarkable cures of grave tubal diseases, the cure being attested by subsequent pregnancy.

Most cases of chronic ovaritis are caused by salpingitis, and the ovarian condition is strictly subordinate. Chronic ovaritis does occur, however, independent of salpingitis, and is a most distressing condition. It produces invalidism, but never death, unless indirectly. Removal of such ovaries is justifiable after the failure of long-continued palliative treatment. This is likewise true of ovaries of the so-called infantile type—cases of partial development with small tubes and uterus. It is equally true that the removal of such ovaries is unjustifiable unless prolonged, well-directed treatment has been employed without success, and the health of the individual case is seriously compromised by the condition.

As it is impossible to remove these conditions by operation, it is plain that medical means alone can be employed. Intraperitoneal exudate from peritonitis may become purulent, when the pus must be evacuated by section; or it may form adhesions which may or may not cause pain or death, according to their nature. Cellulitis ends by resolution or pelvic abscess.

True pelvic abscess endangers life through sepsis, or peritonitis; should rupture into the peritoneal cavity occur, or by exhaustion where the pus has discharged itself spontaneously into the bowel, bladder or elsewhere. At times a spontaneous cure results, which is permanent, because the functionally active viscera are not necessarily crippled by the disease. Such abscesses are similar to those in other parts of the body, and the surgical law of early evacuation is equally applicable to them. They should be emptied at times through the vagina and at times above the groin; more often, another plan should be pursued. Such patients are often extremely ill when seen by the surgeon, and any error in diagnosis is of great gravity. Hence it is often best to do a median section in order to

exclude pyosalpinx and ovarian abscess, and then, if practicable, to evacuate the pus by a second incision above Poupart's ligament.

Having estimated the special dangers of each of the products of pelvic inflammation, there remain some considerations of a more general character.

One of the most distressing results of the failure to remove, especially the graver products of pelvic inflammation, is the occurrence of acute spreading peritonitis. Oftentimes the surgeon sees the patient for the first time when she is in this condition, she having had pelvic inflammation for years. Operation may be offered and done "as a last resort," "to give the patient a chance," and when done under these circumstances death usually follows. What is the cause of these deaths? Who should take the responsibility for these deaths—the surgeon, or the man who, through mistaken teachings, has kept these unfortunate women upon a so-called conservative treatment? The answer is plain—falsely called conservative teaching is responsible for these years of invalidism, with final death.

A class of cases is met with in which the nutrition is depraved, the nervous system has lost tone, and the digestive system is seriously disordered. Such women are best denominated "wrecks." They have had years of so-called conservative treatment, which has proved a dismal failure. Often the local pelvic disease is not great—chronic ovaritis, ill-developed pelvic organs, adherent appendages, or hydrosalpinx. In rare cases pyosalpinx is the condition found; but when pus is present, death usually results too quickly for the profound alterations in nutrition to occur which characterizes this class of women. When such women are operated upon and the pelvic disease removed, the health improves slowly and recovery is often incomplete. Such women often complain of pelvic pain after operation, which is due to the condition of the pelvic nerves, and the general nervous system produced by long years of invalidism. Such cases are often spoken of as demonstrating the failure of the operation to cure. Is not the failure to be attributed to delay—delay till complete restoration to health is well nigh impossible? Undoubtedly the sufferings of this class of women is greater (because longer continued) than any other. It is to be hoped that in the future timely operation will restore them to robust health.

Experience has proved that tubal pregnancy occurs in slightly diseased patulous tubes; the vibratile spermatozoa gain access to the tube, but the impregnated ovum is not propelled into the uterus, owing to lack of vermicular motion in the tube itself, or to the destruction of the ciliated tubal epithelium, or to partial strictures in the tube. This is an ever-present danger when one of the tubes is slightly diseased, no matter whether the other is healthy or profoundly altered by disease. Parvin estimates that one extra-uterine pregnancy occurs for every four hundred pregnancies, and the experience of to-day indicates that his estimate is accurate. What, then, is the probability of tubal pregnancy when a patulous, slightly inflamed tube exists? This question is certainly worthy of consideration in deciding for or against operation in the special class of cases in question. If such tubes were removed, tubal pregnancy could not occur.

The ætiology of tumors is undoubtedly obscure, and perhaps impossible to demonstrate. I have found small, thin-walled ovarian tumors and broad ligament cysts not infrequently when operating for long-standing salpingitis. It has seemed to me that in certain cases the relation was that of cause and effect.

Opposition to the removal of the uterine appendages is based, usually upon the ground that thereby the possibility of the occurrence of pregnancy is taken away. As the function of an occluded tube is destroyed, the objection is well grounded only in reference to the removal of healthy tubes, or slightly inflamed tubes which are patulous. Practically it refers only to the removal of slightly inflamed tubes because no one advocates the removal of healthy organs.

There is no doubt that pregnancy can take place through a slightly inflamed patulous tube; but, as has been pointed out, the pregnancy is likely to be tubal. Under the circumstances pregnancy is scarcely desirable. And this leads to a consideration of the general subject of pregnancy as complicated by salpingitis in its various forms, and by the adhesions resulting from peritonitis. Necessarily one tube must be healthy, or at least patulous, for pregnancy to take place. Instances of pregnancy occurring during the course of serious inflammation, with occlusion of both tubes, are clearly instances of mistaken diagnosis. Upon one side, at least, a mass of peritoneal exudate, or a mass composed of agglutinated bowels, has been mistaken for a distended tube. Given a functionally active ovary with a patulous tube, and pregnancy is possible. The opposite appendage may be seriously diseased—the tube inflamed and bound down, distended

with serum, blood or pus; or the ovary the seat of an abscess or an ovarian tumor. Under such circumstances, is pregnancy to be desired? On the other hand, is not the life of the woman seriously compromised by its occurrence, and especially by the processes of parturition? Is rupture or bruising of the diseased appendage, during labor, with dangerous or fatal peritonitis, to be invited? Or, on the other hand, is it not the part of wisdom to remove the diseased and dangerous structures, and to leave the healthy appendage to provide for future pregnancy? (The indications for unilateral or bilateral operations are omitted as not germane to the subject.)

Conservatism is the part of wisdom; it is that which preserves. In medicine this banner is raised by those who cry "hands off." It is a pertinent question as to whether their course is the part of wisdom, as to whether they really conserve the interests of those concerned—the sick. It seems plain to me that the considerations already presented amply prove that true conservatism lies not in the line of "let alone," but in the line of active surgical treatment. By the let-alone plan diseased organs are preserved that are functionally useless, that destroy the health, or cause the death of their unhapppy possessors. By early operations these diseased organs can be removed, women be restored to health and usefulness, countless years of invalidism be avoided, and many untimely deaths be prevented.

It is only just to say that this paper is based almost exclusively upon the study of cases of pelvic inflammation coming under my own observation. In the beginning my position was exactly the reverse of what it is now; but a widening of experience and the logic of facts forced an acceptance of the views set forth. My own experience has demonstrated to my own satisfaction that the results of (what is claimed to be) conservative treatment are at best negative, and commonly positively bad. In my more recent work many instances of the disastrous results of let-alone treatment in the hands of others have come under my observation.

Conclusions.—All cases of pyosalpinx, abscess of the ovary, hæmatosalpinx, and hydrosalpinx demand operation, unless contra-indicated by grave organic disease of the vital organs. The diseased organs should be removed. When gonorrhœa is the cause of the disease, the operation should be bilateral, even if one of the tubes is healthy. Operation is demanded because these conditions render the uterine appendages functionally useless, destroy health and threaten life.

All cases of occluded, adherent Fallopian tubes demand operation on practically the same grounds. In these cases the probability of death is less, but of invalidism equally great. The earlier the operation the greater the prospect of a cure.

All cases of true pelvic abscess demand operation.

Certain cases of chronic ovaritis and of partial development of the sexual organs demand operation—where health is seriously impaired and medical treatment continued over one or more years has failed.

Finally, the question is submitted for discussion as to the proper treatment of salpingitis with a patulous tube, taking into consideration the facts that at times a cure results, that at times the disease is progressive, and especially that this condition is the determining cause of tubal pregnancy.

Society Reports.

PROCEEDINGS OF THE PHILADELPHIA OBSTETRICAL SOCIETY.

Dr. Chas. P. Noble read a paper on "The Dangers of Leaving the Products of Inflammation in the Female Pelvis (see p. ——.)

Dr. Wm. H. Parish:—The conclusions presented are very safe and proper, and I have no unfavorable criticism to make. Probably most operators agree as to the propriety of operation, but the difficulty is to agree as to the condition actually present. As we all know, in a number of instances eminent gynæcologists have recommended and urged removal of the appendages as an absolute necessity, stating that sterility was present and that the future of the patient was one of great danger. And yet in some of these cases the patients have passed to a condition of fair health, have borne children and continued to enjoy a fair amount of health. This fact, however, has had an unfavorable influence upon the profession; while the publication of such cases should render the gynæcologist particularly careful in his examinations, and show the necessity of becoming a diagnostician as well as an operator.

The difficulty in diagnosing the condition present is considerable. I believe in giving the benefit of the doubt to the patient, and opening the abdomen and removing the

tubes or ovaries, or both. I am not altogether in harmony with the sentiment that it makes little difference whether we diagnose the exact condition or not. I recognize the impossibility of diagnosing the exact condition in many cases, but we should arrive at as close a diagnosis as possible. We should study the symptoms and compare them with the results found at the operation.

There are cases on the border line. If the patient's health is greatly disturbed and she has recurrent attacks of peritonitis, rendering her more or less of an invalid, it is not necessary to wait to demonstrate the presence of pus. The recurrent attacks of inflammation are sufficient to justify the removal of the appendages.

I have seen some curious instances of the difficulties attending the determination of the propriety of operation in individual cases. Not long ago, a prominent lady in this city had suffered for years prior to marriage with intermenstrual attacks of severe pain. The attacks continued after marriage, and a well-known gynæcologist was sent for. After one of these attacks of agony, he believed that she had an extra-uterine pregnancy. Time showed that this was not correct. Operation was, however, recommended. She then visited an eminent member of the profession in a neigboring city who advised her to leave that city very promptly, or she would have her ovaries taken out. He also said that she could not become pregnant. It happened that at the time he made the examination she was pregnant. She returned to this city, and was placed under my care, and a few weeks ago was delivered without difficulty. She had an attack of local peritonitis after delivery, but is now in fair health. She has a diseased ovary and tube on one side, and it may be necessary to operate on this patient. She may have trouble in the future, but this case shows that we cannot determine the necessity for operation in all cases. The point to be particularly dwelt upon is that the general profession is not justified in delaying or preventing operation when recommended by those who have the best opportunities for determining the propriety of operation. The tendency of many patients is to pass from one consultant to another, expecting to find some one who will favor delay. The result is that the delay complicates the condition seriously. Frequently the practitioner says that the operation was unjustifiable, and the fact that death follows shows that he was right in not wanting the operation done. I have heard a busy practitioner say that he had never had a case operated on for abdominal or pelvic conditions that did not die. I said to him: "Probably it is your fault, and not that of the operator." That is frequently the case.

As to pelvic cellulitis, I am sure that Dr. Noble agrees with me that it is a rare condition, and that it is seldom productive of abscess. That it does occur occasionally is true. Chronic pelvic abscess is almost a myth. It may exist as the result of tuberculosis, or be dependent upon disease of the lymphatic glands. Cellulitis, I think, exists only as an acute process following sepsis or labor, and then only occasionally.

In the last few weeks I have seen an extra-uterine pregnancy in a moribund patient, who had been treated by two practitioners for four months as a case of pelvic cellulitis. The patient died from the internal hæmorrhage.

There is one condition of the appendages which I think Dr. Noble did not dwell upon sufficiently, and that is tubercular disease of the appendages. There is strong reason to believe that in a few instances general tuberculosis has begun as a tubercular condition of the appendages. In such cases operation might cure absolutely the patient, or at any rate it might delay for a long time the extension of the tubercular condition to other portions of the body.

Dr. B. F. Baer:—I agree in the main with what Dr. Noble has written. I have passed through the same experience that he has with regard to so-called conservatism in the treatment of inflammatory disease of the ovaries and tubes, and now operate early where operation is required; but at the same time we must not forget that we may operate too soon or operate in cases where the disease is so slight that the patient might go through life and escape serious trouble. Great care and attention should be given to diagnosis, for that must decide the treatment.

Dr. Noble believes that most cases of pelvic disease are due to chronic salpingitis. That may be true, but I doubt it. I find many cases of disease of the ovaries with the tubes apparently healthy. This is especially the case in hæmatoma of the ovaries.

The suggestion that slightly diseased tubes should be removed for the prevention of extra-uterine pregnancy, I think a little too strong.

We do not know certainly that extra-uterine pregnancy is always caused by diseased tubes, nor to what extent the tube must be diseased to bring about that grave accident. There should be symptoms and

physical signs of disease before we operate.

The cases he has characterized as wrecks, require very careful consideration. I have, on several occasions, operated in this class of cases after prolonged palliative treatment had failed to be of more than temporary benefit, and have been sorry that I did so, and I have become very wary of them. If these cases could be operated early, much suffering might be avoided and cure effected, but, as I said, I have learned to regard removal of the ovaries as a means of cure for a broken nervous system with doubt.

In regard to the removal of undeveloped ovaries for amenorrhœa, I agree with Dr. Noble, but this also must not be accepted too literally, for in some cases the menstrual molimina ceases after a while, and the function of ovulation is then quiet. In such cases the removal of the organs would not be necessary. But if the patient is chlorotic and the effort at ovulation continues it would be better if the ovaries were removed.

I agree with Dr. Parish in regard to cellulitis or so-called true pelvic abscess. It is very rare. Some years ago cases of chronic pelvic abscess were met with, but since we have learned to operate early the true pathology has been found to originate in disease of the tubes or ovaries as to the starting point and focus, followed by peritonitis and not cellulitis, except as a secondary or minor complication.

The suggestion that an exploratory laparotomy be first made to determine whether the case be a true pelvic abscess or not, and that if it is found to be such to make an incision along Poupart's ligament, is good, for it will not often be necessary to make the second incision, because by the first the trouble will be found within the peritoneal cavity.

Dr. J. Price :—The ground has been well covered. I am glad to hear Dr. Parish and Dr. Baer speak so plainly on pelvic abscess, a subject which has given us much anxiety and not a little condemnation.

Dr. Noble has called attention to the deaths, and has alluded to the dangers of delay. I have in my hand several letters bearing on this point. One is from a patient. She says: "Dr. —— opened my abdomen for pelvic abscess, but found a mass so large that he could not remove it. He then made an incision in the vagina, and there still exists an opening in my bowel which communicates with the opening in the vagina, through which I pass my motions." In the *American Journal of Obstetrics*, a year ago, Emmett reported cases in which he opened the abdomen and found the adhesions so extensive that he incised the vaginal vault. It has been my misfortune to have many of these cases to deal with.

In all pelvic cases delay not only complicates the operation but diminishes the prospect of a cure. Delay is responsible for that group of cases known as imperfect cures, and these have been cited in opposition to all pelvic surgery. These results are sequelæ of the delay, and not of the operation. If you have to denude the pelvic cavity of peritonæum, or if it has disappeared, there must be adhesions from which the patient may continue to suffer. These are the cases in which a second operation is required for the relief of the adhesions. The second operation cures; the first could not. It saved life, but it could not cure the woman and make her sound and healthy.

Dr. Barton C. Hirst :—I am strongly at variance with some of the views expressed in this paper. That pyosalpinx and ovarian abscess demand operation will generally be admitted, but that hæmatosalpinx, hydrosalpinx and adherent tubes *demand* an abdominal section will not be allowed by many gynæcologists, or by the bulk of general practitioners, who, by the way, have better judgment in these matters than they are often credited with in special societies like this. There are two dangers, I think, which the abdominal surgeon should carefully guard himself against. One is the desire to operate as often as possible, and the other is the disposition to underestimate the dangers of abdominal section. As an illustration of the first, not long ago I heard a prominent gynæcologist describe his sensations while operating. During the progress of the operation he was anxious; he would be glad when it was over; but directly after a rest and dinner he would want to do another. As an illustration of the second, I heard from one gentleman this evening that the mortality of operations for tubal diseases is practically nil, and from another that the mortality may be expressed by one in five hundred. It is, I believe, a knowledge of this tendency that often deters the general practitioner from sending cases to the gynæcologist when he should. My judgment is that these cases of hæmatosalpinx, hydrosalpinx and adherent tubes *may require* operation by the development of symptoms, but that they *demand* it without reservation is not correct. Circumstances should govern us. In women at the Philadelphia Hospital I have operated on slighter grounds than I would in private practice. These women, by slight pelvic dis-

ease, are incapacitated for their work, and their pelvic disease means not only invalidism but pauperism. I have had lately, in private practice—to illustrate what I mean—three women with bad pelvic disease. The tubes are distended on both sides, and in one case there may be pus. These women date their trouble back some years, one twelve years, to a neglected confinement. That woman is somewhat of an invalid, but in good circumstances, and the mother of a large family. She goes to Europe every summer, takes long walks in Switzerland, and enjoys life. I should not dream of operating unless she presented more serious symptoms. The only symptom that annoys her is a recurrent severe hæmorrhage from the uterus at long intervals. I have seen a number of cases in which this symptom was present, but it can be checked by proper treatment.

I am astonished to hear so little said about the mortality of the operation. There is probably not one present who has not seen women die from the operation, who would have lived indefinitely with the condition for which the operation was done. It is a mistake to omit all mention of this.

To my mind it is wrong to lay down a dogmatic rule in regard to operating on these cases. Even where there is pus there are really few who die directly from its presence, but it is true that the great majority come to an operation because their symptoms demand it. In considering other tubal diseases each case must be judged on its own merits, and the man will not do full justice to his patients who is guided by the invariable rule that pelvic inflammation involving any lesion in the tubes demands abdominal section.

In regard to abdominal section for amenorrhœa with ill-developed ovaries, I cannot understand the necessity for operation. There is, however, a condition which justifies operation. There are women who have ill-developed uteri and tubes, but well-developed ovaries. Such persons may suffer intense pain at the menstrual periods. We find the ovaries enlarged. In one such case, that of a girl of 20 years, treated by myself and two others without relief, I operated and found the ovaries unusally large. I also found a corpus luteum as large as that of pregnancy, and yet the girl never menstruated. Her uterus and tubes were unable to drain off the pelvic congestion which occurred every month. In such cases the operation may be demanded, but in amenorrhœa, with imperfect development of the whole sexual apparatus, I do not see the necessity for such radical treatment.

Dr. Chas. P. Noble:—May I ask a question? I would ask Dr. Hirst on what ground he would desire to preserve the tubes where they are occluded and filled with fluid, whether serum or pus? Of what benefit are such organs to a woman?

Dr. Barton C. Hirst:—In all these operations there is a possibility of a fatal termination which should not be lost sight of. Where a woman does not suffer seriously and is able to enjoy life, I should not operate. In the case to which I referred the uterus is firmly bound down. There are tumors on each side of it, and the tubes are distended with fluid; and I should not be surprised if some inspissated pus were present. Even in that case I should not operate unless the woman was absolutely an invalid, or had recurrent attacks of peritonitis.

Dr. W. H. Parish:—Dr. Hirst seems to stand up here as the representative of the general profession to defend it. Dr. Hirst well knows that the remarks that have been made have been directed against certain general practioners. He knows very well that the members of this society are highly appreciative of the general practitioner. I say this because the remarks of Dr. Hirst, when in print, would make it look as if we felt ourselves superior to the general practitioner.

As Dr. Hirst has said, some patients die that might have lived for years, but most of these die because the operation was done too late. That is the reason that I referred to the dangers attending delay. It is more important that we should dwell upon this fact than upon the fact that some die where the lesion is not severe. The number that die from delay or because a necessary operation was not performed is much greater than the number who die from unnecessary operation.

Dr. J. M. Baldy:—I hardly think that any one would hesitate when pus is present, but we must recognize that occasionally the patient may have something to say on the subject. I do not believe that all cases of pyosalpinx die quickly as the author of the paper said. I have operated on cases where pus had been present for eight or ten years. Pyosalpinx can be a chronic as well as an acute trouble. I do not mean that we should not operate. If I had my choice I should operate in every case; but if the woman objected, I would not feel that she must necessarily die. A certain number will, it is true, die quickly, but not the majority.

In regard to the collections of fluid in oc-

cluded tubes, I would say that I do not believe in hæmatosalpinx. With very few exceptions these are cases of extra-uterine pregnancy. Hydrosalpinx is hardly ever fatal. We do not always operate for fatal diseases. As far as the operation is concerned a case may die that should not die. But where one case dies thus, there are hundreds that suffer the tortures of the damned. Sometimes they suffer more from hydrosalpinx than from pyosalpinx. I should advise that cases of hydrosalpinx be operated upon, and I feel that such tubes could be removed with as much safety as simple ovarian cysts—that is, with no mortality. The disease is not liable to kill unless there are repeated attacks of peritonitis. The patient will then suffer as much risk from the peritonitis as from the operation, but instead of running the risk once she runs it three, fifteen or twenty times in as many years.

I can see no reason for treating amenorrhœa by abdominal section or by medicine. If there is amenorrhœa, nature has good reason for it. It is not a local condition. I see no reason for interfering, except with general constitutional measures. If the woman suffers, she does not suffer from the amenorrhœa, but from other conditions. The amenorrhœa is merely a symptom and should be let alone. Many of these cases with ill-developed appendages and uteri have other symptoms than amenorrhœa. If they have great pain, and you operate for that, I have nothing to say against the operation. It is sometimes justifiable.

True pelvic abscess may be met with, but with an experience of three or four hundred sections in my own and other hands, I have not met with it.

In regard to cases of salpingitis, especially those with patulous tubes, possibly this may be one of the causes of extra-uterine pregnancy; but if we are going to remove such tubes to prevent extra-uterine pregnancy, we shall remove half of the tubes in the country. Most married women have inflammation of the tube at some time or other. If we could pick out the cases that are going to have extra-uterine pregnancy, the operation would be proper. In inflamed tubes, with patulous openings, pregnancy may cause complications, but acute or sub-acute inflammation in any part will get well, and I see no reason for operation in these cases until the patient has gone through a long course of treatment. My experience is that most of these women suffer as much after operation as before, so that the trouble, apparently, has not been in the tube alone. It has been a case of mistaken diagnosis. I do not believe that in the vast majority of instances chronic ovaritis is due to salpingitis, nor do I believe that we can always tell chronic ovaritis when we have the ovaries in our hands. The diagnosis is made on the symptoms, and there is nothing more deceptive than symptomology in these troubles. Where there is the greatest disease there may be few symptoms, and where there is little disease there may be severe symptoms.

The "wrecks" I often feel like letting alone. Operation in these cases brings little benefit to the patient and little credit to the operator. The mortality will always be greater, and the results less satisfactory.

Dr. M. Price:—I want to refer to Dr. Hirst's remarks in regard to the country practitioner. In my experience the country practitioner has made the diagnosis and told me what he wanted done. There are few that do not know about pelvic troubles. There is no danger that he will select cases that can go to Europe every summer and walk over the mountainous districts of Switzerland. In the cases that I have seen, the patient insists upon operation. I believe firmly that not a single case of the description laid down in that particular list should die. I never saw one die. The cases that die are those which come in a dying condition. There are a number of cases dying, but it is the operator's fault. We all make mistakes, but I have never operated without knowing that there was something to operate for.

Dr. Joseph Hoffman:—When a man is uncertain of the rules that require him to operate, he must make many mistakes. The man who looks for success must have his reasons and rules before him subject to variation. He must know what cases will give mortality. We have no business to say that hæmatosalpinx and hydrosalpinx will give mortality when simple ovarian cyst does not. In all cases the mortality should not exceed three or four per cent.

How many more go down without operation.

It is a mistake to assume that hydrosalpinx is inoffensive. I have known the most serious symptoms to come on in these cases. Hæmatosalpinx, hydrosalpinx and pyosalpinx are interchangeable. We do not know where the margins lap, we do not know when one will pass into the other. I have seen hæmatosalpinx that was not extra-uterine pregnancy.

In regard to pelvic cellulitis, so-called, Bernutz holds that out of the cases he has

examined post-mortem, pelvi-peritonitis is the cause of visceral adhesions, and is symptomatic of tubal and ovarian disease. Until we have an experience approaching that of that man in pathology, it is fair to believe that there is some error in the opinion. Those who have looked up the doctrine of Nonat have found it wiped out. I do not assert that there may not be peri-uterine inflammation following confinement, but this is not to be considered chronic pelvic cellulitis, for it is a broad-ligament involvement. Inflammation after confinement probably originates in the uterus, but no one will ever find a chronic inflammation of that sort. There is simply an effusion which will pass away. If we use the term cellulitis in this sense, it is misleading.

I think with Dr. Baldy that it is unjustifiable to deal with amenorrhœa as a surgical affection. When a patient run down by some prolonged disease comes with amenorrhœa, we do not think of operation—we treat her by hygienic measures. If the organs are infantile, there is no reason for menstruation.

In regard to carrying pus tubes a lifetime without bad result, it has been demonstrated beyond question that although pus may be carried a long time, yet it always makes disease somewhere else. Pus anywhere else in the body is always let out—why not in the pelvis?

Dr. G. Betton Massey:—With all due deference to Dr. Noble, I must say that the paper appeared to me very much like a patent medicine advertisement. We are given a succint list of diseases and are told to take for each—not so-and-so's bitters, but an operation. The author of the paper has perhaps unconsciously, fallen into the error of looking upon one thing as a panacea, giving routine directions for treatment by an operation which runs the risk of killing the patient, and this in spite of the impossibility of exact diagnosis. As has been so often said on this floor, very few of these conditions can be accurately diagnosed, with the exception, perhaps, of large pus tubes or cystic ovaries.

To go to the root of the matter, most of these diseases are, it is true, one or another phase of inflammation, but is it not the duty of the physician to combat this process rather than remove some of its products? The argument of the paper tends to obscure the fact that, taken in time, this process can be arrested by local and general treatment.

Gynæcologists should pause and reflect on the singular extravagance of the position assumed by some. In what other specialty are the products of inflammation cut out unless they are encysted or purulent? We should combat inflammation itself rather than amputate a part because it is inflamed. Should we cut out a tube because it is adherent, if the woman can be freed from all pain or trouble referable to it? We do not cut out a lung because it is adherent to the chest wall as a result of pleurisy. I maintain that if we can relieve the patient permanently there is no occasion for more radical measures in any of the conditions mentioned in the paper.

Dr. C. P. Noble:—My object in reading this paper was to elicit discussion on the broad subject of pelvic inflammation, and I am glad that its object has been accomplished—discussion elicited. I was led to write it by the remarkable communication which appeared in the *British Medical Journal* by two "obstetric physicians," Drs. Williams and Champneys, and by the paper recently read by Dr. Baldy in this Society. The English physicians utterly fail to appreciate the advances made in gynæcology during the past fifteen years. They accept ovariotomy as justifiable, but reject operation for the removal of diseased uterine appendages. Dr. Baldy, also appears to be very doubtful of the grounds on which he stands. Under the circumstances, it seemed to me that a general discussion of the subject would be of advantage to us all. Dr. Parish referred to mistakes in diagnosis and prognosis. I alluded to that in my paper, incidentally. There is no doubt that such errors reflect badly upon surgery, and they discourage the general practitioner from accepting the teachings of to-day. Although he is wise in his own department, he is not necessarily an expert in pelvic disease. My own opinion in regard to these mistakes is that the diagnosis is made too quickly, often from a single examination. Mistakes are made most easily if the examination is made shortly after an acute attack of peritonitis. Finding a fixed mass the examiner concludes that it is a distended tube or a bound-down ovarian tumor, whereas it may simply be an exudate around the tube or ovary. Of course, if the patient is dying from the condition, we do not care what it is, we have to operate to save life; otherwise, the physician should aim at exact diagnosis. The mistakes in prognosis in regard to sterility usually come about in this way. There is found a mass of exudate, or the bowels are bound together, and it is concluded that the tubes are distended and occluded, and a prognosis of sterility is given, although the conditions present need not en-

tail sterility. Such mistakes can only be avoided by greater care, especially by a longer study of cases before giving an opinion. It is difficult to speak concerning pelvic cellulitis, and especially pelvic abscess, before this Society, because it is a fashion here to distort one's statements concerning these conditions. No one believes more strongly than I do that the ordinary form of pelvic inflammation is salpingitis with peritonitis, yet I have seen pelvic cellulitis and true pelvic abscess. Because some gentleman has not seen it, am I to doubt the evidence of my own senses? Those gentlemen who say that it does not occur make some egregious blunders. Those cases in which inflammation occurs after labor, with great masses of exudate in the pelvis, and the women get well and bear children, are cases of acute puerperal cellulitis. These masses are exudates. In the processes of labor, lacerations occur; and if there is infection, cellulitis may follow. I have seen three true pelvic abscesses within two years, in which the abdomen was opened and nothing found the matter with the tubes. I shall report these in full at an early day. At the same time, it is not the less true that in many cases of puerperal pelvic inflammation cellulitis does not occur. The inflammation is confined to the vagina or to the uterus; or it spreads along the tubes, and at times to the peritoneum. The very wonderful researches of Bernutz have been referred to wrongly to-night. Bernutz did not claim that pelvic abscess does not occur, but that cellulitis does not take place, as Nonat held, in the cellular tissue, between the uterus and its peritoneal covering and immediately adjacent to the cervix. He admits that we have what he calls iliac phlegmon and abscess in the broad ligament and peri-rectal connective tissue. His claim is that what he and we recognize as tubal disease is not cellulitis of the tissue between the uterus and the peritoneum, as is claimed by Nonat. All honor to him for demonstrating the fact! I have also seen cellulitis after laparotomy, where the stump has become infected. I am sure that many cases of so-called hæmatoma after section, as mentioned by Tait, are nothing but cellulitis, possibly with peritonitis, of the broad ligament—an infected pedicle. I did an exploratory section in one case that demonstrated this absolutely.

With regard to salpingitis as a cause of ovaritis, I said that most cases of *ovaritis* were caused by salpingitis, not most cases of ovarian disease. I would not at all hold that very many cases of ovarian disease, cystic ovaries or ovarian hæmatoma or cystoma are caused by tubal disease.

In the paper I carefully abstained from dogmatism regarding the proper treatment of salpingitis with patulous tubes, because I feel that the subject is debatable. I should hesitate to operate in all cases of slight tubal disease. But these conditions are not the simple affections that we are apt to consider them, and they may lead to serious trouble. In reference to Dr. Hirst's remarks, not to remove pelvic disease unless of the gravest character, I have only to say that I differ with Dr. Hirst. I think that it is such teaching as his that is the cause of most of the deaths in abdominal surgery. In these cases of slight disease there should be practically no mortality. If the vital organs were healthy I should never expect death; and the operation should not be done unless the viscera be healthy. One death in several hundred would be an ample allowance. This certainly would not weigh against the many deaths which would occur in such cases from neglect.

Dr. Baldy states that I hold that patients with pyosalpinx die quickly. In general the course of pelvic inflammation, complicated with pus, is not a long one, but there are exceptions. I said in the paper that some cases of pyosalpinx get relatively well, although crippled and useless appendages were left in the pelvis; and I have removed a tube containing a pint of pus that the woman had carried for seventeen years. Another was of eight years' duration. The first woman was an absolute wreck. For two years she has been relatively well.

Amenorrhœa was not referred to in the paper. The cases referred to were those in which menstruation does occur, although imperfectly, and with great pain; and often intermenstrual pain is present. Where the lack of development is extreme we have amenorrhœa, but I should think that such cases would seldom present symptoms calling for removal of the appendages. The cases that I have seen have been great sufferers and have been subjected to all forms of palliative treatment without benefit.

I did not refer to wrecks from other causes than pelvic disease. It would be folly to remove the tubes and ovaries in wrecks from other causes. The results in these cases are not brilliant, but have been good enough to encourage me to continue to operate, always giving a guarded prognosis as to final cure, and insisting upon the necessity for prolonged treatment after the operation.

I do not know that I have anything to say in answer to Dr. Massey's remarks. His arguments doubtless appear cogent to him, or he would not advance them, but to me they are pointless. It seems to me that he overlooks entirely the natural history of pelvic inflammation and also the results and dangers that follow, if diseased structures are left in the pelvis.

SELECTED FORMULÆ.

ERYSIPELAS.

Dr. Rothe (*British and Colonial Druggist*) has used an ointment prepared as follows:

℞
Creolin..... 1½ parts.
Creta præp.
Axung. porc.....aa.....15 "
Ol. menth. pip..... 5 drops.

This is spread in the thickness of the blade of a knife over the diseased parts twice or three times a day, a thin layer of cotton-wool being applied as a covering.

ABORTIVE TREATMENT OF HERPES.

Leloir (*La Tribune Médicale*) recommends a small piece of gauze soaked in one of the following solutions to be applied:

℞
Resorcin.....grammes 100.
Alcohol (90 per cent.)..... " 2.
M.

Or,

℞
Menthol.....grammes 1.
Alcohol (60 per cent.)..... " 100.

If there is much pain use can be made of

℞
Cocainæ muriat.....gramme 1.
Ext. cannabis indic.....grammes 10.
Essen. menth. pip..... " 10.
Alcoholis (90 per cent.)..... " 100.

PARASITICIDE OINTMENT.

L'Union Médicale gives the following ointment for the destruction of parasites:

℞
Salicylic acid.....45 grains.
Borax.....15 grains.
Balsam of Peru.....30 grains.
Ethereal essence of anise..... 5 drops.
Essence of bergamot.....20 drops.
Vaselin..... 6 drachms.

Make into an ointment and apply to the part affected.

GARGLE TO PREVENT DENTAL CARIES.

℞
Tannin..... 5 gm.
Tincture of iodine
Tinct. of myrrh, aa.....2½ gm.
Iodide of potassium..... 1 gm.
Rose water.....180 gm. M.

S. A teaspoonful in a glass of water, to be gargled every morning.

—*Nouveaux Rémedies.*

NIGHT-SWEATS.

The following prescriptions for the relief of night-sweats are published in the *Revue Général de Clinique et de Thérapeutiqué:*

℞
Sulphate or tannate of quinine.....gr. xv.
Powdered ergot..... .....gr. xxx.
Divide into four powders, and take two or three in the course of the day.

This prescription is also valuable in cases having a tendency to hæmoptysis. Or,

℞
Powdered agaricine.....3j.
Make into four powders, and take one powder at night.

℞
Powdered agaricine.....3j.
Powdered belladonna-root.....gr. vij.
Divide into four powders, take one powder at night.

℞
Powdered agaricine.....3j.
Tannin.....3j.
Make into four powders, and take one or two powders a day.

—*Medical News.*

INDIGESTION WITH CONSTIPATION AND FLATULENCY.

A favorite perscription of the outdoor medical department of the Jefferson Medical College Hospital, in cases of difficult digestion accompanied by constipation and flatulency, is the following:

℞
Tinct. nucis vomicæ
Tinct. belladonna
Tinct. physostigmatis, aa.....f 3ij.
Ext. cascaræ fluid.....f 3vj.
Ext. erythroxylon, q. s.....f 3iij.
M. Sig. A teaspoonful after each meal.

NEW TREATMENT OF HERPES ZOSTER.

MIXTURE.

℞
Extract gelsemium, Sodium sulpho-carbolate } of each..... 4 grammes.
Distilled water.....90 grammes.
Teaspoonful every two hours.

At the same time 5 drops tincture of belladonna are administered every two hours until a slight dryness of the pharynx is experienced.

LOTION.

℞
Lead acetate, Powdered alum } of each.....4 grammes.
Distilled water.....120 grammes.
M. Sig. Externally.

Compresses moistened with this solution are applied to the affected parts, and renewed every two hours. According to the author, pain disappears within a few hours, and the disease is considerably shortened by this treatment.—*Merck's Bulletin.*

LOCAL ANÆSTHETIC FOR COMPARATIVELY PAINLESS EXTRACTION OF TEETH.

As one of the great corps of "country doctors" who act in almost every capacity for their patrons, I submit the following formula as a local anæsthetic for the almost painless extraction of teeth:

℞

Hydrochlorate cocaine..... 5 parts.
Crystal. carbolic acid..... 6 parts.
Pine gum camphor..... 6 parts.
95 per cent. alcohol q. s. to make 120 parts.
Mix.

Inject one to three minims of this mixture, with a hypodermic syringe, deeply into the gum on the inner and outer sides of the tooth. Apply over the gum a piece of absorbent cotton wet in the solution. Wait four to five minutes. The gum can then be freely incised, and the tooth drawn with a minimum amount of pain. Try it.—J. Wilton Hope, M. D., *Va. Med. Monthly.*

BROMIDES WITH BISMUTH AND NAPHTHOL.

Pharmacists have been surprised of late at the number of prescriptions they have had of the bromides united with bismuth and naphthol. They have now discovered the cause. M. Féré, of the Salpêtrière, finding that large doses of bromide of potassium disagreed with such of his nervous patients as had gastric troubles, sought for a combination which would enable him to give the bromides with impunity. He finally settled upon the following formula:

℞

Bromide of potassium.....6 grammes.
Beta-naphthol.....4 grammes.
Salicylate of bismuth.....2 grammes.
Divide in 3 doses, and give 1 dose three times daily.

This is the prescription which many physicians are now trying for their nervo-gastric patients. Some of them add $\frac{1}{30}$ grain of sulphate of strychnine to the above.—*Paris Letter in Pharm. Record.*

HYDRASTININE IN MENSTRUAL HÆMORRHAGE.

Falk has found that hydrastinine is very effective in congestive dysmenorrhœa, menstrual hæmorrhages due to a change in the texture of the uterus, in metrorrhagia due to endometritis, in myoma, etc. He orders the following:

℞

Hydrastinini muriat.....¾ gr.
Ext. glycirrhizæ, q. s.
Ft. tal. pil. No. X.
Sig. Take one or two pills daily.

One pill should be taken a few days before the hæmorrhage begins, and two while it continues.—*St. Louis Med. and Surg. Journal.*

TRINITRINE FOR ANGINA PECTORIS.

Trinitrine or nitroglycerin has been very largely used, particularly in France, in the treatment of angina pectoris, and is without doubt a valuable remedy for this disease. According to the studies of Huchard, Potaie and Herard, who have studied its physiological action particularly in relation to its use in angina pectoris, the drug is a vaso-dilator resembling very closely nitrite of amyl. Bocquillon uses it in the following manner:

℞

Alcoholic solution of trinitrine
(1 per cent.).....30 drops.
Distilled water.....10 ounces. M.
Two teaspoonfuls morning, noon and night.

For subcutaneous injection he uses the following solution:

℞

Alcoholic solution of trinitrine
(1 per cent.).....30 drops.
Cherry-laurel water..... 3 ounces. M.
Twenty minims of this may be given hypodermically.

—*Med. News.*

TO REMOVE DARK COLOR FROM COMEDONES.

The *British Journal of Dermatology*, February, 1891, gives the following prescription of Unna and Leistokow for removing the unsightly "black-heads" which are so often an annoyance to a patient and a trouble to the physician:

℞

Lanolin..... 10 parts.
Vaselin..... 20 parts.
Peroxide of hydrogen.....20-40 parts.

LACTIC ACID IN INFANCY DIARRHŒAS.

Dr. Thomas claims excellent results from the following mixture in gastric or gastro-intestinal dyspepsia, characterized by nausea, vomiting, flatulence and diarrhœa with non-slimy fœtid, yellowish or greenish stools:

℞

Lactic acid.....℥j.
Simple syrup.....℥v.
Water.....℥iijss.
M. Sig. ℥j every quarter to half hour after meals.

—*Rev. med. de la Suisse Romande.*

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

EDWARD T. REICHERT, M. D.,

PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF PENNA.,

EDITOR AND MANAGER.

N. E. Cor. 13th and Walnut Streets,

P. O. Box 843. Philadelphia, Pa.

THE MEDICAL AND SURGICAL REPORTER.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent 3 months on trial for $1.

At the termination of the period of subscription, we will promptly discontinue sending THE REPORTER unless directed to the contrary by the subscriber.

Remittances should be made by draft, check, postal note, or money order payable to Edward T. Reichert.

THE POCKET RECORD AND VISITING LIST.

Two sizes. Prices to subscribers of THE REPORTER: For 30 patients a week (with or without dates), $1.00. For 60 patients a week (without dates), . . $1.25. Prices to non-subscribers, $1.25 and $1.50 respectively.

THE MODEL LEDGER.

Physicians who keep their own books will find this of great value. Sample pages sent on application. Price, $5.00.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If THE REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS.

Write in ink.

Write on one side of paper only.

Write on foolscap or legalcap paper.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be pleased to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

LEADING ARTICLES.

HYPEREMESIS GRAVIDARUM.

Concerning no subject in obstetrics has there been greater confusion of ideas than the uncontrollable vomiting of pregnancy. Each writer has had a different theory concerning its essential nature, and the list of remedies and cures which have been vaunted is a long one. Prominent among the theories which have been advanced concerning its pathology are the following:

1. The theory of Bennet that the vomiting is often due to inflammation of the cervix. 2. That of Hewitt, that it is due to mechanical causes, as flexion or version or incarceration of the uterus, or to undue hardness or rigidity of the tissues about the *os internum*. 3. That of Veit and others that it is due to inflammation of the uterus, especially to endometritis. 4. That of Kaltenbach, that it is hysterical in nature. 5. And finally, the old theory that it is a reflex act, proceeding from the development of the pregnant uterus which is free from disease. Each of these theories is based upon studies of cases, and can be amply illustrated; hence, each must be accepted as containing a basis of fact.

It seems to us that the present status of this subject is far more satisfactory than it has been in the past. If well settled principles have not been formulated, at least well settled facts concerning the condition are in our possession which must be of the greatest value to the well informed physician in his management of cases of this affection. But is it not also true that sufficient facts are before us to justify certain conclusions? It is well known that pregnancy influences the entire system of the gravida, and that the nervous system is profoundly influenced by the condition. The nervous system becomes more irritable—grievous effects are produced by lesser stimuli, no matter what their peripheral origin. It is equally well established by clinical evidence that pregnancy causes vomiting—even though the *modus operandi* be obscure. If this increased irritability of the nervous system be accepted as the basal fact in hyperemesis gravidarum, the entire

subject becomes wonderfully simplified. Certainly a good working basis is attained. When the individual comes before the practitioner, his duty is not done when he makes the diagnosis. This simply gives him the cue for the general management of the case, the avoidance of all sources of irritation of a general nature, the regulation of the secretions of the body, the use of suitable diet, and the administration of drugs to lessen the irritability or to increase the tone of the nervous system. But his task is just begun. He must determine the particular causation factor or factors in the individual case, whether it be an inflammation of the cervix, the uterus or its appendages ; or a displacement or hyperæsthesia of these organs ; or some condition of the general system which is depressing vitality ; or, finally, if it be hysteria. Each case becomes a special study, and a full diagnosis is to be made only after careful investigation.

Were all the facts now before the profession concerning the pernicious vomiting of pregnancy generally known and appreciated, death from this cause would occur less often. The practitioner who treats it in a perfunctory way until the victim is in extremis, or tries the more rational methods of treatment after it is too late, or calls in counsel to discuss the advisability of inducing abortion when she is beyond assistance, fails in his duty.

A WORTHY PROJECT.

Among medical men in this country may frequently be found those who, by stress of conditions beyond control—the toil of a tiresome calling, and the aches and pains that come to them, oftimes in larger measure than to those they serve—have gone down before the imperious power of Opium, Chloral or Cocaine.

Most of them, perhaps, are well enough off in this world's wares to compensate one who may extend a helping hand to draw them out of the narcotic slough, but some—many, we have reason to think, are not so happily situated, and plod wearily on, longingly waiting for the time when it will be their good fortune by dint of improved conditions to secure the succor desired. This is no fancy picture—we know of just such cases.

These and their friends will be glad to know that there is now the chance of getting such wished-for relief " without money, without price"—an opportunity nowhere else offered—and under conditions that promise most largely the result desired. We refer to the Brooklyn Home for Habitues, recently opened in that city under the care of a gentleman who has long given exclusive attention to narcotic disease, and is regarded among the highest authorities in his specialty in America.

This Home, a spacious building with especially attractive surroundings, is now open, and one-fourth of it free to worthy applicants too poor to pay. It is full and the requests for its care from indigent habitues will tax its resources for months to come. Of these requests thus far, the Medical Director informs us that thirty per cent. have been from physicians. This fact proves our opening assertion, and fully emphasizes the need of such a resort. To care for these an endowment of $60,000 is now being secured, the income from which will be devoted wholly to this purpose. They receive the same care and attention as the other cases and the fact that they are free patients is known only to the Medical Director.

The Board of Directors comprises well known physicians, clergymen and others in Brooklyn and New York and its five consultants are all eminent in their special fields.

Subscriptions to the endowment fund, none of which will be called for until the entire amount is subscribed, are solicited. We commend this good project to every doctor in the land, for his generosity will go to aid a poor but worthy brother in distress. Donations may be sent to the editor of this journal and will be duly acknowledged or to the Medical Director of the Brooklyn Home, Dr. J. B. Mattison.

CORRESPONDENCE.

A CASE OF MONSTROSITY.

ED. MEDICAL & SURGICAL REPORTER :—

I delivered on the 13th inst. a case of monstrosity of the anencephalia kind which is worthy of being put on record.

A multipara aged, 19 years, second child. There was none of the upper cranial bones present nor any development of the brain. The two parietal, frontal and occipital bones were absent and with no sign of development of their centers. There was also a complication of spina bifida of the upper part of the cervical vertebra to the extent of one inch. It lived about fifteen minutes and was able to move around. It did not or could not cry. The lower part of face and body was perfectly developed and weighed about 7½ lbs.

The woman had a fall during her first month of pregnancy which may have been the cause.

Her labors were always complicated with too much liquor amnii, the last time about two gallons. Yours truly,

DR. H. C. W. SHOWALTER.
New Holland, Pa.

PERISCOPE.

THERAPEUTICS.

EUPHORIN.

Dr. Sansoni, in the *Journal de Méd. de Paris*, May 17, 1891, is said to have employed euphorin as an antithermic, antiseptic, antithæumatic and sometimes also as an analgesic.

As an antithermic Sansoni gives the drug in powder form, either in capsules or dissolved in a glass of wine. The dose varied from 0·50 gramme to 1·50 grammes daily. He has used the drug in many febrile diseases, both acute and chronic, including typhoid fever, pneumonia, phthisis, acute rheumatism, etc. A lowering of temperature takes place rapidly and lasts for about five or seven hours. The lowest point is reached in three hours. It is frequently preceded by a chill. After exhibition of the drug the skin becomes slightly red in color and then breaks out in a profuse perspiration.

It is a fact worthy of comment, that weak subjects endure the drug better than vigorous ones; in the latter the temperature not frequently falling below normal. But in these cases the patient experiences a feeling of well-being or light-heartedness, from which symptom the drug has received its name. In patients under 15 years of age, it is not well to give more than 0·5 gramme within twenty-four hours. Indeed, as a rule, Sansoni advises that initially the drug should not be given in doses larger than 0·1 gramme. The reduction of temperature is occasioned by dilation of the peripheral blood-vessels.

In order to obtain an antirheumatic action, euphorin must be given in larger doses than when using the drug as an antipyretic. At least 1 to 2 grammes must be given within twenty-four hours, and the action is better when large single doses are given than repeated small doses. In chronic rheumatism larger doses are required than in acute rheumatism. In the latter the drug's action is both rapid and effective, the pain and swelling quickly disappear and the temperature drops. In some cases of chronic rheumatism, of a stubborn character, in which all other remedies (including antipyrin and the salicylates) had been used without avail, the action of euphorin was excellent.

As an analgesic the drug is of a special value in orchitis; less in sciatica, trigeminal neuralgia, the lacinating pains of tubes; and with scarcely any action in intercostal neuralgia and migraine. The dose should be from 1 to 2 grammes daily.

Euphorin in powder form is an excellent antiseptic, and will be found of great value in the treatment of indolent ulcers, and chronic ophthalmia. In a few days the diseased surface will assume a healthy appearance, suppuration will cease, and healing will be rapid. The application of euphorine powder will occasion a little pain.

A CASE OF POISONING FROM THE EXTERNAL USE OF TOBACCO.

Dr. Aucké reports the following curious and interesting case to the *Wiener Medizinische Presse*, July 12, 1891. The patient was a man suffering from pediculi pubis. He took 200 grammes of tobacco and boiled it down in two litres of water, and then proceeded to "rub in" the mixture over his entire body. After this performance he did not wipe himself off, but sat in the wind and dried. This was done in the morning, and at about half-past one in the afternoon he repeated the experiment. At three o'clock he was suddenly seized with violent nausea and dizziness; his face grew dark, cold perspiration streamed from his body, which

assumed an extreme pallor; and his hands and feet trembled. The patient felt as though intoxicated, and seemed to be looking through a fog, being unable to distinguish the contour of any object. His pupils were enlarged, but re-acted to the light. He could hear well, but said he felt as though cotton were stuffed in his ears. Vomiting occurred from time to time. Besides this, the heart's action was much slower than normal, and the radial pulse, small, thready, and scarcely perceptible.

These conditions lasted for about three hours, after which they gradually abated. The next day the patient only complained of a severe headache, which a long sleep, however, relieved.

This case proves that tobacco used externally can give rise to the same toxic symptoms as when taken internally.

The reporter of the case fails to state whether the pediculi were affected or not.

FLUID EXTRACT OF HYDRASTIS CANADENSIS FOR THE NIGHT-SWEATS OF PHTHISIS.

Dr. Cruse, of Curlands, reports to the *Medicinische Neuigkeiten*, July 11, 1891 that while giving the fluid extract of hydrastis canadensis for pulmonary and renal hæmorrhages, the existing night-sweats in the patients treated simultaneously disappeared. This was very markedly the case in the last stages of phthisis. In one case of phthisis accompanied by night-sweats, which although primarily controllable by atropin, agaracin, etc., but which finally remained unimproved by any treatment, the fluid extract of hydrastis was given with very beneficial results. Dr. Cruse gave thirty drops of the fluid extract every evening. Later, however, he discontinued the drug but the night-sweats had not reappeared up to the time of his making the report (over three weeks). Experimenting further, Dr. Cruse found the remedy to be both prompt and efficacious in all cases of this kind. The initial dose was always thirty drops, every evening, which was increased if indicated.

ARISTOL IN DISEASES OF THE EAR AND NOSE.

Professor K. Burkner, of the Göttingen University Clinic for Diseases of the Ear, states in the *Berlin Klin. Woch.* that aristol was so warmly recommended to him as an antiseptic and a cicatrisant, that he felt impelled to institute extended trials of it in Polyclinic and in practice, for patients suffering from diseases of the ear and nose. Rohrer was the first to announce the results obtained by the use of aristol in ear diseases. He used it in acute and subacute, middle ear inflammations, by insufflation, after drying the cavity. There resulted a rapid decrease of secretion and tumefaction, and an early healing of the perforation. Aristol was quite as serviceable in otitis externa and ozœna. Rohrer reports twenty cases in which the effect of aristol was better than that of the usual remedies, especially boric acid, iodoform and iodol. Pirii, in 182 cases of rhinitis ulcerosa, ozœna obtained very good results from the use of aristol in powder, and aristol ointment. Massini obtained excellent results in fœtid rhinitis by the use of aristolized tampons.

Prof. Burkner has employed aristol as a powder and as an ointment, and has also used it intimately mixed with glycerine. In eight of his cases the suppuration was promptly removed. In fourteen cases the result was gained, but not so rapidly. In ten cases there was some increase of secretion.

Aristol proved to be exceedingly valuable —as also stated by Szenes—in determining the formation of granulations in the tympanic cavity, or auditory canal. Of twenty-two cases (of which a portion had been treated by lunar caustic with little benefit) thirteen showed under aristol, a very rapid improvement. Within a few days the proliforations had completely, or very considerably, dried up. In six cases there was a somewhat less marked improvement. In three cases of otitis diffusa externa, with suppuration, the condition yielded quickly to treatment by aristol.

Prof. Burkner also obtained very satisfactory results from the use of aristol in nasal diseases. He tested it in twenty-six cases, of which three were nasal syphilis, fifteen non-syphilitic ozœna, and eight were cases of granulative formations.

The effect of aristol in a large majority of the above cases was really surprising. Headache occurred very rarely, and lachrymation was insignificant as compared with what generally follows other remedies used in the form of powder.

After the first treatment by aristol the fetor often disappears at once for twenty-four hours. On longer treatment the fetor vanishes for days at a time, and a cure is finally obtained. The appearance of the mucus membrane quickly improves on the

atrophic surfaces, as well as in their neighborhood, when the surrounding tissue is hypertrophied.

Ulcerous conditions of the syphilitic origin, showed a remarkable tendency to heal after a very short use of aristol. This remedy is, in these cases, second to none of those usually employed.

As in ear cases, so also in nasal cases, the proliferations of granulation tissue were very rapidly improved. In many of his cases the granulations were permanently removed by insufflation of aristol, or by tampons impregnated with that preparation. He noted that aristol excited a less considerable hypersecretion than other remedies, such for instance as iodoform.

For affection of the nose, aristol constitutes a noteworthy enrichment of our treasury of therapeutic agents; and he also recommends its use in aural therapy, in which it should receive a very entended trial.

ACTION OF ALOIN.

Professor Meyer has chemically and physiologically examined aloin obtained from Barbadoes, Curaçoa, and Natal aloes (*Archiv. f. expt. Path.*, xxviii, Heft 3 and 4, 1891). Barbadoes and Curaçoa aloes yield an identical aloin, the former contains about 10 per cent., the latter about 16 per cent. It has the formula C_{16} H_{16} O_7, is in yellowish white acicular crystals, soluble in hot water and alcohol, much less so in acetic ether, and only in traces in chloroform, ether and benzol. Natal aloes yield about 14 per cent. of a different aloin, having the formula C_{24} H_{26} O_{10}, scarcely soluble even in hot water, soluble in 70 parts of boiling alcohol, very soluble in caustic soda, from which it is precipitated unchanged by acids. In experiments on animals and man the aloin was given *per os* and subcutaneously. For subcutaneous administration a solution in formamide was used—water may also be used for Barbadoes aloin, but the solution is more liable to decompose; the solution has a neutral reaction, and after injection causes burning pain for a few minutes but otherwise has no evil effects. The aloin can be detected in the fæces and urine by tests which are given at length and which are extremely delicate. The experiments showed that aloin from Barbadoes and Curaçoa aloes acted with certainty as a purgative, whether given by the mouth or subcutaneously. The dose in both cases is about the same, which is explained by the fact that aloin, when given hypodermically, is excreted from the blood chiefly into the bowel, only a mere trace or none being found in the urine. In man, dogs, and cats there is no albuminuria after subcutaneous injection, but in rabbits—in which animals aloes does not cause purgation—subcutaneous administration is always followed by inflammation of the kidneys, albuminuria and death. Its purgative action is as slow when it is given hypodermically as it is *per os*. The resin left after extraction of the alion from aloes is also purgative. Natal aloin was active in dogs and cats only after very large doses; but if an alkali were added to it—so as presumably to decompose it—its activity was greatly increased. By subcutaneous injection it was always active. In man, on an ordinary mixed diet, given alone or with an alkali, it had very little purgative effect, but in man fed on an exclusively animal diet, it was much more active. The reason probably is that in the latter case the putrefactive processes in the intestine are much more marked, and the aloin is decomposed into a more active substance. All the experiments seem to point to the conclusion that aloin itself is not an active purgative, but that it becomes gradually decomposed in the intestine into a more active body, and hence the slowness of its action.

—*Brit. Med. Jour.*

THE TREATMENT OF HÆMOPTYSIS.

In a paper published in the *Zeitschrift fur Therapie* for April I, 1891, Prof. Nothnagel calls attention to the fact that the most essential feature in the treatment of hæmorrhage from the lungs is that the patient should be kept absolutely quiet, should not be allowed to speak, the room should be kept at a moderate temperature, and he should eat nothing warm, and his food should be of the most readily digestible character, cold milk being preferable to anything else; and, in fact, Prof. Nothnagel advises that for two days the diet shall be confined solely to cold milk. It used to be taught that coughing was of assistance in removing the blood from the bronchi, but this is now recognized as being an extremely hurtful teaching, and the first attention should be directed towards suppressing coughing, and for this purpose morphine is the chief remedy. When the hæmorrhage is only moderately severe, nothing further need be given to the patient than morphine; but when, as occurs in many cases, the hæmorrhage does not spontaneously cease, then other remedies have to be given.

At first Prof. Nothnagel calls attention to

the remedies which ought not to be given, remedies which have been frequently recommended, and which yet may produce most disastrous effects. First of all in this connection he calls attention to the sesquichloride of iron. This as is readily comprehensible, is only of use as hæmostatic in external hæmorrhages, and then likewise only when those hæmorrhages come from capillary vessels. Even in the hæmorrhage which may follow the extraction of a tooth, it must be used with the greatest care. As is well known, this remedy causes coagulation of the blood, and so leads to the formation of a thrombus, while its constricting action on the blood-vessels is so slight as not to be worth attention. When given internally, even if it is absorbed, which is extremely doubtful, it must form other combinations, and then will only produce the action of any other iron preparation which evidently would lead to an increase of the bleeding; and it is an old rule, but a good one, that individuals with a hæmorrhagic tendency must be very cautious in the use of iron preparations. As a consequence, then, the internal use of the solution of sesquichloride of iron is neither theoretically nor practically of the slightest use. The same remarks apply to tannic acid and alum. These remedies only serve to constrict the blood-vessels when applied in dilute solutions. So also inhalations of all kinds should be strictly prohibited on account of the more vigorous respiration which this mode of treatment entails, and the consequent danger of increasing the hæmorrhage instead of diminishing it. When, however, a violent hæmoptysis is to be treated, two substances are named, which may be of great service. The first of these is ergotin, which acts on the unstriped muscular fibre of the blood-vessels, and which may be given both internally and subcutaneously; the second remedy is the acetate of lead, which may be given in doses of from $\frac{1}{2}$ to $\frac{3}{4}$ grain. There is still another remedy which might be employed with some prospect of success, although Nothnagel states that he has as yet had no experience with it, and that is *Hydrastis Canadensis*. Atropine also, in subcutaneous injections of $\frac{1}{64}$ grain, has likewise been claimed to do good. As to the use of common salt, given in teaspoonful doses, it is not clear as to whether the arrest of hæmorrhage, so frequently reported to follow its employment, are coincidences or consequences of the treatment. At any rate, it can do no harm, and may do good, when nothing else is obtainable. As regards the application of cold externally, Nothnagel is very doubtful as to its value; for, in the first place, is is very uncertain as to whether the cold either directly or reflexly will succeed in producing vascular contraction at the affected part; and in the second place, the application of cold to the surface of the thorax produces direct coughing, and coughing is certainly much more dangerous than the possible constricting value of a cold application.

Finally, Nothnagel alludes to the heroic measure of bleeding from a vein to arrest hæmorrhage from the lungs, a proposition based upon the observation that a violent hæmorrhage in leading to syncope often causes the arrest of bleeding. Of course such a procedure as bleeding for a hæmorrhage from the lungs can be dismissed without discussion.—*Ther. Gaz.*

APHORISMS IN MEDICAL EMERGENCIES.

Accidents in Giving Anæsthetics.—Tincture of digitalis hypodermically; draw out the tongue, and see that respiration is not mechanically impeded; invert the patient quickly and temporarily; use forced respiration promptly; apply external warmth and stimulation to the surface; avoid the exhibition of alcohol.

Angina Pectoris.—Inhalation of chloroform, or of a few drops of nitrite of amyl; $\frac{1}{100}$ grain of nitro-glycerine, internally; placing the feet in hot water; mustard to the pecordial region; dry cup between the shoulders; hypodermic injections of morphine and atropine; administration of stimulant and anodynes.

Apoplexy.—Elevate head and shoulders; if pulse is moderately strong and the brain congested, bleed from the arm freely, sixteen ounces or more; elaterine (gr. $\frac{1}{6}$) or croton oil, two drops in a drachm of sweet oil or glycerine; cold to the head by means of an ice-bag.

Asphyxia.—In drowning, hold the patient's head downward for a few seconds. In hanging or choking, bleed from the jugular. If there is obstruction to passage of air through mouth or nose, open trachea. Artificial respiration at once, and to be continued. Friction, warmth, warm bath (100°), ammonia to nostrils, galvanizing of phenic nerve.

Asthma, Spasmodic.—Hypodermic injection of atropine into the nape of neck; inhalation of smoke of stramonium leaves; fluid extract of nux vomica, internally, alcohol, ether, chloral, opium; inhalation of chloroform cautiously administered.

Colic, Gall.—Morphine hypodermically;

inhalations of chloroform; hot application to the abdomen.

Coma.—Dark room, head high and cool; head shaved; low diet; croton oil; if due to compression, antiseptic trephining; if due to uræmia, pilocarpine and hot baths.

Heat-stroke.—Remove clothing, sprinkle with water, cold cloths to head, hot cloths to feet; antipyrin; bleeding in robust subjects. After temperature is reduced give alcohol and diffusible stimulants, hypodermically if necessary.

Pulmonary Hæmorrhage.—If severe, raise the thorax, administer opiate; gallic acid fifteen grains every fifteen minutes; ergotin five to ten grains hypodermically two to three times daily; ice-bags to the chest; as a last resort a ligature may be thrown around the larger limbs. (Tyson.)

Hæmorrhage from Stomach or Bowels.—Tannic acid ten to fifteen grains if due to capillary oozing. If from typhoid fever or ulcer of the stomach, treat as for pulmonary hæmorrhage.

Hiccough.—Acid drinks, cold douches, ether or chloroform internally, externally, or by inhalation; musk, opium, antispasmodics.

Hysteria.—Inhalations of ether or chloroform for the spasms. If this is contra-indicated, give mono-bromide of camphor, musk, valerian, assafœtida, the bromides. In convulsive seizures, morphine and atropine hypodermically.

Shock.—Warmth; hot water bottle to feet, flanks and epigastrium; warm effusion to head; horizontal position; frictions, stimulants, brandy, ammonia, galvanism to precordia.

Strangury.—Vesical, hypodermic injection of morphine, to be followed by other remedies; rectal enemata of starch water and laudanum followed by a hot sitz bath.—*E. J. Kempf., M. D., in Am. Pract. and Nems.*

THE PHARMACOLOGY OF ASPARAGUS.

The influence of the active principles of asparagus on the renal function does not appear to have been very clearly made out, and although for some reason or another a general impression prevails in favor of its ingestion being followed by a diuretic effect; this view is not based on reliable data. Indeed, there are grounds for believing that it not uncommonly exercises a disturbing influence on the renal functions, causing in some instances a notable decrease in the amount of urine excreted. It is very improbable that any injurious effect is produced on the healthy organism, or this succulent vegetable would not have become a general favorite. As, however, it may possibly give rise to undesirable symptoms in particular cases, it is as well that the profession should be made acquainted with the real nature of its physiological action, and we shall look to our scientific pharmacologists for some information on this point.—*Med. Press.*

MEDICINE.

CHOREA—ITS PATHOLOGY AND TREATMENT.

Chorea is a neurosis probably produced by irritation in the motor centers of the cerebrum, through which the influence of the will over motion is disturbed. In isolated cases it may be caused by capillary emboli or other changes in the lenticular nucleus.

Psychical influences or anæmia, perhaps by the vasomotor disturbance of the motor centers which they occasion, are the most frequent causes of chorea.

Chorea frequently follows rheumatism. Most probably the same irritant which produces rheumatism may, by its effects on the motor centers, bring about chorea.

The frequent coincidence of heart affections and chorea is largely due to the etiological connection of both of these diseases with rheumatism. Still, it is possible that heart affections may give rise to vasomotor disturbances in the motor areas, and that recent endocarditis may produce capillary emboli in the same locality, both of which phenomena might readily cause chorea.

The therapeutics recommended by different authorities vary according to the view which they take of the etiology. Thus some recommend chiefly nervines and tonics; others recommend anti-rheumatics; while still others lay the greatest stress on the treatment of such heart affections as may be present.

I shall speak only of those medicines which are shown to be efficacious by the unanimous testimony of a large number of clinical reports. This claim can in reality be substantiated only for arsenic and antipyrin. There can be no doubt that these two drugs do certainly shorten and ameliorate the course of chorea. They must, however, be given in sufficiently large doses.

As less important, though still useful in the treatment of chorea, I wish to recommend iron for those cases in which anæmia exists, and chloral hydrate for those in

which there are great restlessness and insomnia.

So much for the medical treatment of chorea. I will now consider the physical treatment. Some authorities recommend absolute mental and physical quietude for choreic patients. Others recommend gymnastics as a cure, claiming that it improves the general nutrition as well as the nutrition of the muscles, and that furthermore it tends to bring the muscles back under the control of the will. My own experience teaches me that all mental exertion is to be avoided, likewise all bodily exertion, except such as is conducted strictly under the direction of the physician. Certain movements must be made before the patient, and he must imitate them, at the same time watching carefully the execution of his movements. From simple we must gradually go to more complex exercises, always carefully avoiding fatigue. Thus methodical gymnastics will be found to aid greatly other treatment.

Massage and electricity do not seem capable of accomplishing much in the management of chorea.

As to balneo- and hydro-therapy in chorea, I would say that I do not think it well in the acute stage to deprive patients of their home and comforts and send them to resorts.

After the acute stage has passed cold water treatment in the shape of baths or otherwise may be a useful adjuvant in suitable cases. The patient's peculiarities must be regarded, his manner of reacting and his antipathy for cold temperatures should be taken into account. Never should he be excited. Shower baths are very seldom applicable. Warm or lukewarm baths are sometimes preferable to cold ones. Especially in cases complicated with rheumatism and heart disease should cold water be abhorred. When the heart trouble is acute, no baths at all should be employed.—Dr. Groedel, in *Deut. Med. Zeit.*—*Weekly Med. Rev.*

A RARE CASE OF HEPATIC ABSCESS.

Dr. Joseph Gabriel says: On Aug. 29th, 1890, I was called to see Sheik Khalee, aged thirty-two, a native of Hayoum, in Upper Egypt. He was suffering from pain in the right side; his face was pale; tongue coated white; pulse 100; temperature 102°, with irregular fits of chill; respiration short and rapid. According to the patient's statement his illness was of one month's duration, during which he was getting worse every day. On inquiry regarding his habits and his previous illness, he said that he had been in the habit of drinking intoxicating liquors, which he stopped five years ago; a year before this date he suffered from intermittent fever, and he did not have dysentery. Physical examination showed that on percussion the pain was increased, and the area of liver dulness was larger than usual, but I could not detect any fluctuation; urine of natural color. I had no doubt that my patient was suffering from inflammation of the liver, and probably commencing abscess. I gave him a solution of diluted nitro-muriatic acid, sulphate of quinine, and tincture of rhubard, and applied a blister on his right side. On Sept. 3rd I again visited the patient, and found him very little better. He complained of pain in the right shoulder; his bowels were irregular. I told him to continue the medicine, and perscribed in addition akaline mineral waters. On the 10th his temperature was almost normal; pain considerably less, but he looked very weak still, and had no appetite. I told him to continue taking the mineral waters, and applied a second blister on his side. On the 20th I visited him again, and found him walking in the garden. Upon examination I found everything normal; he was apparently cured, and enjoyed good health during two months, at the end of which he was suddenly attacked by dyspnœa and a severe cough, and expectorated a material like chocolate in color. I examined the expectoration, and found it composed of pus cells and broken-down liver tissue. I ordered him a stimulant, tonic medicine, nourishing food, and left the case to nature. He still expectorates, and up to the present time he expectorated about 400 ounces, but has strength sufficient to go about and fulfil his ordinary duties.—*Lancet.*

SURGERY.

PHAGOCYTES.

It is a matter of common observation in surgery that solid materials in contact with living tissue undergo erosion and diminution of bulk, and, under favorable circumstances, altogether disappear. The most familiar example of this occurrence is necrosed bone in contact with granulations. The worm-eaten appearance of the sequestrum, its separation from the living bone, its diminution of bulk, and in some cases its total disappearance without exfoliation, indicate that it has

been eaten away. This process can best be watched in cases of denuded skull in which the growth of granulations through the outer plate and the coalescence of these and the gradual absorption of the intervening white bone can be clearly seen. Ivory pegs, catgut stitches and drains, decalcified tubes are capable of being partially or wholly consumed in the same way. It is not a case of disintegration by maceration and subsequent absorption of the molecules. The worm-eaten aspect of the fragments negative this idea, as well as the fact that when the material is bathed in pus and is not in contact with granulations it does not undergo diminution of bulk. The absorption of particles of pigment from the skin and the conveyance of these particles to the interior of lymphatic glands by the cells, in which the coloring matter can be seen, is another instance in point. The efficient agents in this process of erosion are undoubtedly leucocytes, which carry the foreign material inwards for excretion, or outwards, in the process of suppuration, for emission. This remarkable and salutary property of wandering and amœboid cells in the animal organism has acquired a new and singularly striking interest through the researches of Dr. Elias Metschnikoff, who has demonstrated that the amœboid cells of the body, fixed and free, possess the property of enclosing microbes in their protoplasm, and digesting or disintegrating them. This is a novel illustration of the exercise of the *vis medicatrix naturæ*, and has led its discoverer to enunciate a new theory regarding natural and acquired immunity against diseases arising from the introduction into the body of pathogenic organisms. The process of prehension of micro-organisms by the pseudopodia of phagocytes is, according to this theory, denominated phagocytosis. In some cases the cells manifest a quick attraction for the microbes and rapidly envelope them; in other cases they display a repulsion. These attitudes are termed *positive chemiotaxis* and *negative chemiotaxis*. The exercise of either of these depends on the peculiarities of the animal and the chemical qualities of the material. Malignancy implies negative chemiotaxis and *vicé versa*, and negative can be converted into positive chemiotaxis by preparation of the organism by means of protective inoculation. Immunity may be natural when the animal is, as it is called, refractory, or acquired when an animal naturally susceptible is rendered refractory by vaccination. In both cases immunity is coincident with, if not caused by, the existence of strong positive chemiotaxis. This theory presents us with a struggle between two contending elements—the phagocytes on the one hand and the microphytes on the other. Victory on one side means immunity or recovery from disease; victory on the other means illness or death. The theory is an exceedingly plausible and fascinating one, and is applicable to the ordinary phenomena of inflammation as well as to the phenomena of microbic infection. A very lucid statement of it will be found in the *British Medical Journal* of the 31st of January in a translation of a lecture delivered by Dr. Metschnikoff himself at the Pasteur Institute. In this lecture the facts on which the theory rests are clearly set forth, the bearing of these on the question of immunity very intelligently discussed, and sundry theories which would explain immunity in other ways criticised with much ability and force. We strongly commend this lecture to the attention of those who may desire fuller information on this most interesting and important topic.—*Indiana Med. Gaz.*

HOW TO KEEP NEEDLES FROM RUSTING.

Dr. Robert H. M. Dawbarn, writes in the *N. Y. Med. Jour.:* It would be an interesting point to determine how many of your readers are agreed regarding the best way of keeping their various surgical goods and chattels ready for instant use. In talking with other surgeons I find many opinions about it.

As to needles, for instance. I think the majority, after sterilizing them by heat, try to keep them dry. Dry sterilizing at the usual temperature is apt to injure their temper and cause subsequent bending during use; boiling or steam, to induce specks of rust. Rust, too, results from occasional subsequent exposure to air; and if cotton or cloth is used, this attracts moisture. Should a film of vaseline or oil be applied as a protective, this causes dust to cling, and requires fresh cleansing before use. Glycerin I have tried and found wanting. In it, hygroscopic as it is, the needles do not remain entirely untarnished. They finally turn black.

For the past year I have been pleased with the results of a new plan—new to me, that is, though very probably not to others. This is simply to keep my needles in alcohol. For extreme safety against rust, I use absolute alcohol; but the commercial article would probably be efficient. At least, some needles which I have kept in common

alcohol for a month as an experiment are as bright as ever.

Upon buying the needles, I immerse them in benzine to remove grease. Then, after running them through a towel, I plunge the point (a cutting-edge Hagedorn) into a bit of cork of the size of a pea—to avoid dulling from jolting—and finally, with their corks, they are put and kept in a wide-mouthed, glass-stoppered bottle filled with absolute alcohol.

After use, I sew through a thick, wet, soapy towel repeatedly, cleanse the eye with a thread, immerse in benzine, and finally replace in the alcohol. This is certainly an efficient disinfectant, besides being an excellent protector against rust.

By the by, I long ago gave up using (save in bowel work) any other than Hagedorn *self-threading* needles, which are a decided comfort, and, when properly made, do not cut the thread.

GYNÆCOLOGY.

ACCIDENTS RESULTING FROM INTRA-UTERINE CAUTERIZATION WITH CANQUOIN'S PASTE.

Pichevin (*Nouvelles Archives d' Obstét. et de Gynécol.*, No. 2, 1891) concludes that the time has come to refute the arguments which have been advanced to legitimize the employment of a therapeutic measure which theory condemns in advance. He feels that it is necessary to furnish some facts, the eloquence of which is such that men of good faith and physicians desirous of the interest of their patients may renounce positively a preceeding which, as someone has written, is "a manifestation of atavism." Many who have employed caustics in the uterine cavity at some time in their practice are strongly opposed to this method of treatment to-day. Avan spoke of cauterizations of the cervix with the paste of the chloride of zinc, but was far from recommending this treatment. Bennet makes mention of the retractions which he had observed in women whose cervical canal had been cauterized. Scanzoni was strongly opposed to the employment of the caustic of Filhos, and Nonat reports great constriction of the utero-vaginal orifice following the use of Vienna paste. Bernutz and Goupil, after treating a young woman suffering from metritis by Vienna paste, reported an occlusion of the neck with menstrual retention. Emmet, Schröder, Martin, Mundè and others, all record themselves as opposed to cervical and intra-uterine cauterizations.

The advocates of the treatment by cauterization are strong in their opposition to the method of treatment by curetting the uterus. They claim that the latter is an operation which necessitates prolonged and rigid antiseptic precautions; that it places the surgeon under the necessity of making a previous dilatation; that it demands a chloroformization, which is "always formidable;" that it gives rise to a loss of blood which is at times very great; that it is a rather grave and complex operation; that it compels the surgeon to practice forcible depression of the uterus; that it is not successful when the uterus is retro-displaced; that it does not give better results than the other procedures which have been advanced for the cure of endometritis; and, finally, that it causes atresia. In answer to these propositions, Pichevin, declares that *curage* of the uterus has been adopted by the immense majority of surgeons. Antisepsis, he says, is beyond doubt indispensable before, during and after the operation; slight dilatation is useful, but not indispensable. As for chloroformization, it may be omitted; but for the sake of the patient it has become the custom to resort to anæsthetization. The quantity of blood which escapes during and after the operation is absolutely insignificant. Moreover, hæmorrhage—when it exists before the intervention—is arrested as by enchantment in the very great majority of cases. The abrasion of the uterine mucosa with a dull or cutting curette is not a complex operation. There is nothing more simple. Forcible depression of the uterus is not necessary. It suffices to fix the cervix with the aid of a small forceps. When the uterus is retro-displaced, the metritis will be cured under the influence of the curette, but it is necessary to replace the organ in its normal position. The abrasion of the uterine mucosa is not an infallible method of treatment for endometritis, but no procedure can be compared to it. As to subsequent atresia, Pichevin has never observed it in his practice.

On the other hand, the apostles of intra-uterine cauterization claim the following advantages for Canquoin's paste in the treatment of endometritis:

1. It is unnecessary to perform minute and prolonged antisepsis.

2. It is unnecessary to practice a previous dilatation.

3. It is unnecessary to anæsthetize the patient. The introduction of the stick of Canquoin does not occasion any pain. As

to consecutive pains, they are rare, ordinarily but slightly marked, and of short duration.

4. The treatment does not necessitate a long rest. The patient is cured at the end of some days.

5. There is no hæmorrhage produced by the cauterization.

6. Atresia does not result, or if it is noticed it is an exceptional occurrence. In any case, the cervical constriction is not special to this mode of treatment.

7. The intra-uterine cauterization is efficacious. The cure obtained from the stick or pencil is real and durable.

8. The innocuous nature of this intervention is undeniable.

9. The introduction of the stick or pencil of chloride of zinc into the uterus is simple and easy.

To these propositions Pichevin offers the following refutations: While Polaillon strongly advocates the employment of intra-uterine caustics, he admits that antiseptic injections are indispensable while the scar is forming and eliminating itself, and during all the time necessary for the cure. Dumontpallier likewise says that the day of the operation being determined, frequent vaginal injections, about three *per diem*, should be made before the operation, employing a solution of sublimate 1 to 2000 or 1 to 3000.

Grandmaison and Bock recommend antiseptic washes for the external genitalia, with vaginal and intra-uterine injections of sublimate while the eschar is being cast off. Bock injects into the uterus tincture of iodine, perchloride of iron, or silver nitrate. It will thus be seen that the advocates of this method themselves largely employ antisepsis. As to the previous dilatation, Polaillon recognizes the fact that in certain cases it is necessary to introduce a laminary tent, or to perform a slight dilatation with a uterine dilator. Grandmaison and Bock have also been compelled to dilate. Several of the followers of this method of treatment have testified to the severe pain which has been produced by the caustic agent. Reynier noticed that injections of morphine failed to relieve these sufferings. In ten operations Dr. Jacob has, with but one exception, noted very severe pains attendant upon cauterization. As far as rapidity of cure is concerned, the statements that the patients who have undergone cauterization are discharged in a few days cured are gravely erroneous. Bock, the Belgian defender of the system says: "The time necessary for a cure will be from three weeks to three months." Jacobs, Polaillon and Batuaud report cases of violent hæmorrhage following the separation of the eschar, thus confuting the claim of the adherents of cauterization as to the entire absence of bleeding. The efficacy of cauterization has not been demonstrated by the reports which have been published. In fifteen operations Deletrez reports but three cures, while Jacobs has ten relapses in ten cases. Neither is the method of treatment entirely free from unfortunate complications. In one hundred observations Dumontpallier reports four peri-uterine complications (two cases of pelvic peritonitis and two abscesses of the broad ligament). Following the application of caustics to the uterus, the state of the menstruation has been in several instances altered. Dysmenorrhœa and irregular menstruation, with increase of flow, has been noted by different operators.—*Med. News.*

CONSTIPATION AND ITS RELATION TO PELVIC DISEASES IN WOMEN.

Root (*Southern Medical Record*, May, 1891) calls attention to constipation as a frequent factor in pelvic diseases of women. The habit of constipation is largely due to carelessness, especially in childhood. In the adult female, constipation is very frequent, and many of its symptoms point to pelvic disease; pain in the back, pain in the top and back of the head, a feeling of weight in the limbs, dysmenorrhœa and leucorrhœa, subjecting the patient to local treatment, when changes in the modes of life, with relief of constipation, would restore health. It is also very evident that this disease acts as a most active factor in the production of pelvic disease in women; for where endocervicitis and even retroversion exist, rapid improvement is made as soon as constipation is relieved. Pelvic disease results from constipation through pressure and keeping up a constant condition of sluggishness of the pelvic circulation, amounling practically to a chronic congestion. Many cases of pelvic disease can be cured by the proper regulation of the bowels, and he cites cases in proof of this statement.—*Univ. Med. Mag.*

OBSTETRICS.

TREATMENT OF RUPTURE OF THE UTERUS.

In considering the question of laparotomy Leopold *Archiv f. Gyn.* asks us to remember that hæmorrhage which may be insignificant

externally, may be considerable and dangerous within. After laparotomy, hæmorrhage being controlled and the abdominal cavity cleansed suture the rupture, if possible, or plug uterus and vagina with iodoform wick, and draw another through the tear and lower angle of the abdominal wound. Subsequent treatment according to the usual rules. In rupture of the uterus the child should be delivered so as to cause the least risk to the mother; not by turning, as that would extend the tear, but by perforation or embryotomy. If engaged in the lower pelvis, deliver manually or by the forceps. Laparotomy should alway be performed at once and under strict antiseptic precautions in cases where the child has escaped into the abdominal cavity. The danger to the mother increases strictly as to the time since rupture and the force used in attempting delivery, these factors leading to exhaustion and infection. The death of the child follows very soon after rupture. Although the mother may show great shock, if assistance is prompt and the hæmorrhage successfully controlled, the prognosis is good in the worst cases. Uterine rupture at the vesico, uterine fold is more frequent than is generally supposed. The hæmorrhage is not necessarily severe, and may be closed by forced antiflexion of the uterus by pressure and bandage, together with plugging the ruptured uterus and vagina with iodoform gauze.

MERTRITIS DISSECANS.

Dr. Höchstenbach (*Archiv f. Gynäk.*, vol. xxxvi, part. ii) describes a case where the first labor was lingering. The membranes were ruptured too early; the os was long in dilating. The forceps was applied to the head of the still living child before complete dilatation of the os. Four attempts at delivery failed. Sixteen hours later, the child was extracted, dead, with the forceps. A rent in the perineum was sewn up at once. *Post-partum* hæmorrhage set in, and the placenta was detached with the hand. The uterine cavity was washed out with an antiseptic lotion. Within an hour symptoms of septic infection set in. Stinking gases and pus escaped from the uterus, sloughs of vaginal mucus membrane were discharged, and a vesico-vaginal fistula formed. Metastatic pneumonia set in, and on the twenty-sixth day after birth a large slough, consisting of uterine and vaginal tissue, was expelled with free fœtid purulent discharge. The pyæmic symptoms passed off for awhile, the vagina and uterus becoming practically closed. A plastic operation was performed half a year later for relief of the fistula. Three months later the patient died of pyæmia. A necropsy was performed, and the former existence of metritis dissecans was authenticated. The uterus and vagina showed the effects of extreme cicatrical contraction. Extensive plugging of veins, metastatic abscesses in the left kidney and lung, and left hip-joint disease were also discovered. Dr. Höchstenbach has collected twelve cases of metritis dissecans; three proved fatal, two through sequelæ of infection, one from rupture of the thinned uterus during injection. This case is a warning to obstetricians; it shows how caution should be exercised in the management of injections, especially when there is much fœtid discharge. Diagnosis is easy as soon as the sloughs begin to escape. All the twelve cases could be traced to puerperal infection. One patient had typhoid, one syphilis; these constitutional diseases may have encouraged local septic infection. It is not certain whether the disease begins as primary necrosis of the uterine tissue, through plugging of its vessels with coagulum or germs, and subsequent demarcation by an inflammatory process, or as destruction of the uterine tissue by primary inflammation and free exudation.—*Brit. Med. Jour.*

VOMITING OF PREGNANCY.

Dr. Graily Hewitt has recently published a work on this subject, in which he reiterates his frequently-expressed views as to the causation of this distresssng symptom. He endorses the opinion of many authorities that the vomiting is a reflex act which starts from the neighborhood of the internal os, and he claims that the irritation arises from malposition of the uterus, causing compression at this part, and his treatment therefore consists chiefly in reposition of the displaced organ. —*Exchange.*

PÆDIATRICS.

STERILIZATION OF MILK.

Petri and Maassen (Arbeiten aus dem K. Gesundsheitamte, *Deutsche med. Zeitung*, No. 45) reports observations made upon 1,800 bottles of sterilized milk, 600 of these having been examined for bacteria. It is possible, as they found, to obtain by sterilization milk absolutely free from germ life. Several con-

ditions, however, bear upon this point. Firstly the composition of the milk at the time of sterilization, a permanent preparation being possible only when the milk is fresh and free from impurities; next, the time of sterilization; and lastly, the storing of the already sterilized milk in cool places. By sterilizing we destroy the pathogenic organisms of anthrax, cholera, typhoid, tuberculosis, diphtheria, erysipelas, suppuration, as well as the bacteria of blue milk, etc. The sterilized milk has a certain cooked taste, easily distinguished from fresh milk, but by no means unpalatable, so that, as a rule, it is readily taken.

Hesse (*Zeitsch. f. Hygiene*, same reference) has arrived at the following conclusions as a result of his work upon the question of sterilization:

1. Milk suitable for sterilization can only be obtained from healthy, dry-fed, and carefully tended cows.

2. All possible contamination of milk up to the time it is placed in the sterilizer is to be most carefully guarded against.

3. If possible, sterilization should be effected immediately after milking. If this cannot be done, the milk is to be at once cooled and maintained at a low temperature. Even then, not more than a few hours should elapse before sterilization.

4. To avoid the cracking of bottles in the sterilizer, the latter, filled to about four-fifths of their capacity, should be introduced into the sterilizer cold, and the temperature gradually brought up to the boiling point; or, what is preferable, first warmed with their contents and then subjected to the proper heat.

5. The milk is to be brought to the boiling point, the temperature being indicated by a thermometer penetrating into the interior of the apparatus. Once this degree is reached, the process is to be continued for an hour and three-quarters. Then the milk is truly sterilized. In bottles made of green or brown glass it will keep indefinitely. White glass bottles should be protected from the direct rays of light.

6. Every bottle should be tested, immediately before using, with reference to taste and odor.

It is believed safer for each family to sterilize its own supply for daily or weekly consumption, rather than to depend upon articles of commerce, which, being prepared in much larger quantities, are thereby also more liable to contamination or subsequent accidents.

Guérin has recently suggested, as a substitute for sterilization, freezing of the milk, in elastic reservoirs, so that it may be carried in blocks, like ice. Such milk, upon thawing, has the taste of fresh milk, can be churned, or boiled just as fresh milk can. It can be preserved for two or three weeks, if kept at a suitable temperature. The preparation, however, always requires the use of an ice machine and suitable non-conducting receptacles for milk, and is hardly as practicable as sterilization.—*Lancet and Clinic.*

CONVULSIONS AS A CAUSE OF CEREBRAL HÆMORRHAGE IN EARLY LIFE.

Ashby (*Practitioner*, June, 1891) refers to the difficulty of determining whether in those children who are hemiplegic, and who give a history of severe convulsions, these caused minute hæmorrhages which gave rise to the convulsions, or whether the convulsions and the hemiplegia were both caused by hæmorrhages. He is inclined to think that often the convulsions are the cause of the hæmorrhage, and he gives the following case to support this view: A child, twelve years old, was brought to the hospital suffering from right hemiplegia. The history given was that at the age of two years he had several severe convulsions attributed to indigestion; before these he was apparently quite healthy, but afterwards it was noticed that the right arm was useless, and he dragged the right leg. Until the age of ten he had many fits, but since then he has been free. He died of tuberculosis a few months after admission. The brain appeared healthy when examined externally, but on section several small old blood cysts were found in the neighborhood of the corpora striatata on both sides, but they were very much larger on the left side than the right. Dr. Ashby believes that at the age of two the convulsions gave rise to the hæmorrhages, and the paralysis supervened upon them, for there is nothing whatever to indicate that any thrombosis, embolism, or arteritis could have caused the hæmorrhages.—*Brit. Med. Jour.*

HYGIENE.

BORIC ACID, &c., AS FOOD PRESERVERS.

A few months ago a person who sold milk, which had been deprived of part of its cream, and which contained some boric acid, was heavily fined by a London magistrate. The fine was imposed, partly on account of the debasement, partly because of the pres-

ence of boric acid. This substance, with or without its sodium salt (borax), and salicylic acid are largely employed in the preservation of cream and other ready perishable articles of food. In some countries the nature of food-preservatives is inquired into by the authorities, and such of them as might be prejudicial to health are prohibited. In Berlin no preservative of any kind is allowed to be put into milk. In Holland salicylic acid as a preservative is interdicted, although previously it was largely used, especially in beer. In France, salicylic acid is not allowed to be used; and in Spain and Italy, preservatives other than alcohol are not permitted to be added to wines. In these countries, bisulphites are frequently used to keep beer from becoming sour, and the practice seems to have had some sort of official recognition by the Excise authorities. As to the effects of the continuous use of boric acid, borax, and salicylic acid upon health, opinion is divided, but the weight of it is against their use. The medicinal dose of boric acid is from 5 to 30 grains for an adult, and 2 or 3 grains for a child. From 5 to 12 grains of boric acid and mixtures of borates are added to a pint of milk; a child using a pint of milk would, therefore, take a big dose of the antiseptic. It may be that these bodies do not affect one's health when used in the proportions in which they are found in food; but it seems irrational to suppose that compounds which prevent the evolution of organisms, and arrest chemical changes in organic bodies, would have no influence upon the processes of digestion. The whole subject of the use of antiseptics in food ought to be carefully considered.—*Dublin Journ. Med. Sci.*

SPREADING DISEASE BY THE CLINICAL THERMOMETER.

An article in the *Medical Record*, May 16th, headed "Dentistry and Syphilis," reminds me of the thoughtless and filthy manner I have seen the clinical thermometer used by physicians, and that by physicians of good standing and undoubted ability. I cannot call your attention to any particular case that would demonstrate, without doubt, my views; but my conviction is sufficient to prompt me to make the assertion that disease is often conveyed by the clinical thermometer.

I have seen the thermometer used when the amount of mucus accumulated on it was so great as to make it almost difficult to see the register. The majority of practitioners wipe the instrument off with a handkerchief, towel, or even the bedclothing, and carefully place it away in a case prepared with a small amount of absorbent cotton in the bottom to prevent breaking, and, unintentionally, to preserve the germs from time to time, to be conveyed to the next unfortunate, who may be the first patient called upon.

I make it a rule to clean my thermometer every time it is used, whether I suspect any infectious disease or not, at the patient's residence. I use soap and water, and if no disinfectant is at hand, I use, on my arrival at my office, either boracic, carbolic, or corrosive sublimate solution, in order that I may use my thermometer with a clear conscience when it is again needed.—L. M. Powers, M. D., in the *Medical Record.*

TRANSMISSIBILITY OF SYPHILIS.

As published in his magnificent *Atlas of Venereal and Skin Diseases*, Prof. Morrow's conclusions in reference to the hereditary transmission of syphilis are:

1. A syphilitic man may beget a syphilitic child, the mother remaining exempt from all visible signs of the disease; the transmissive power of the father is, however, comparatively restricted.

2. A syphilitic woman may bring forth a syphilitic child, the father being perfectly healthy; the transmissive power of the mother is much more potent and pronounced, and of longer duration than that of the father. When both parents are syphilitic, or the mother alone, and the disease recently acquired, the infection of the fœtus is almost inevitable; the more recent the syphilis, the greater the probability of infection, and the graver the manifestation in the offspring.

3. While hereditary transmission is more certain when the parental syphilis is in full activity of manifestation, it may also be effected during a period of latency when no active symptoms are present.

4. Both parents may be healthy at the time of procreation, and the mother may contract syphilis during pregnancy, and infect her child in utero. Contamination of the fœtus during pregnancy is not probable if the maternal infection takes place after the seventh month of pregnancy.

MEDICAL CHEMISTRY.

CHLORAL-PHENOL AND PHENOL CAMPHOR.

Chloral has the property, when rubbed with certain bodies, such as camphor, of

forming therewith syrup liquids. With phenol (absolute carbolic acid) it also liquefies, and a preparation composed of equal parts of phenol and chloral is used in medicine for allaying toothache, as well as for its antiseptic properties. A recent study by Fabini, says the *Chemist and Druggist*, shows that chloral-phenol possesses the odor and taste of its constituents, and when applied to the skin produces inflammation and an eruption of small blisters. It is a colorless and clear liquid, having a sp. gr. at 20° C. of 1.289, so that it sinks in anhydous glycerin. It is soluble in alcohol, acetic acid, amyl-alcohol, chloroform, carbon bisulphide, and glycerin, as well as in ether when slightly warmed. It is only partially soluble in petroleum ether, and benzine only dissolves a little of the fluid, and what is dissolved is chloral phenol. Fabini tested the fluid thoroughly, with a view to determining whether it is a mechanical mixture, and it behaved in every way towards re-agents as carbolic acid does, while with sulphuric acid some of the chloral-phenol yielded, after twenty-four hours, a velvet-colored plaster-like mass, which consisted of meta-chloral and phenol-sulphonic acid. There seems to be no doubt, therefore, that chloral-phenol is a mixture.

This preparation should not be confounded with the phenol camphor devised by Cockrane (not campho-phénique), and made by mixing together 1 part of carbolic acid and 3 parts of camphor. After twenty-four hours this becomes a liquid, having a sp. gr. of .990. It is used with oil as an antiseptic. As a spray it may be applied to the skin to produce local-anæsthesia. It may be employed for disinfecting surgical instruments, and upon wool and gauze for wound dressing. It is soluble in alcohol, ether, and oils, but not in water or glycerin. Menthol, cocaine, salicylic acid, iodoform, chloral dydrate, and mercuric chloride are soluble in phenol camphor.—*Pharmaceutical Record*, June 11, 1891.

THE PRESENCE OF ALCOHOL IN COMMERCIAL ETHER.

If a clear mixture of 4.5 volumes of a saturated solution of potassium bicarbonate and 1 volume of a saturated solution of mercuric chloride is shaken up with commercial ether, the mixture becomes turbid in ten to twenty minutes, and a white, amorphous, precipitate separates out. If further quantities of ether are added, all the mercury is eliminated except traces, whilst the substance which reacted upon the ether is withdrawn from the mercurial solution.

The yellow or brown color imparted to commercial ether on the addition of potassium hydroxide is occasioned by alcohol.—*Arch. d. Pharm.* and *Chem. News.*

NEWS AND MISCELLANY.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

The Mississippi Valley Medical Association will hold its seventeenth annual session at St. Louis, Wednesday, Thursday, and Friday, October 14, 15, 16, 1891. Reduced rates and an excellent programme will bring out a large attendance. The medical profession is respectfully invited. The officers are as follows: C. H. Hughes, M. D., 500 N. Jefferson Avenue, St. Louis; E. S. McKee, Secretary, 57 W. Seventh Street, Cincinnati, Ohio; I. N. Love, M. D., Chairman Committee of Arrangements, 501 N. Grand Avenue, St. Louis, Mo.

TRI-STATE MEDICAL ASSOCIATION.

The Third Annual Meeting of the Tri-State Medical Association will convene in Turner Hall, Chattanooga, Tenn., Tuesday, October 27th, 1891, and continue in session three days. Indications are that it will be one of the largest Medical meetings ever held in the South. Representative physicians from all sections will be present.

All who desire to read papers should send title to the Secretary of the Association before September 1st. In due time a circular will be issued giving a complete list of all papers and names of exhibitors who apply for space before October 1st.

W. L. Gahagan,
Sec'y of Executive Com.,
P. O. Box 542. Chattanooga, Tenn.

THE NUMBER OF TUBERCLE BACILLI IN PHTHISCAL SPUTUM.

Dr. E. H. F. Nuttall, of Johns Hopkins University, has shown that phthiscal patients expectorate from 250,000 to 4,000,000,000 bacilli in twenty-four hours. Taking the average of, we will say, 100,000,000 per day, the patient would expectorate 365,000,000,000 bacilli a year, and if he lives three years, the total number of micro-organisms ex-

pectorated during his illness would be 1,095-000,000,000. Or multiply the year's annual out-put of 365,000,000,000 by 70,000, the number of cases of phthisis in this country, and we are confronted with the sanitary problem of destroying 75,000 times 365,000,-000,000 microbes every year. These are rather discouraging figures, but it may be supposed that the vast majority of tubercle bacilli in the sputum die as the result of intercurrent disease or a pitiless environment. —*Med. Rec.*

HOW DOCTORS LIVE.

A correspondent of the *Medical Age* says: "I have endeavored to keep track of 100 of my medical friends after graduation, especially of what they did during the first five years, and find nearly 75 per cent. had to resort to other employment to make a living. Twenty-three received a salary either in addition to practice or separate therefrom. Fifteen were proprietors of drug stores. Three were insurance agents. Four loaned money. One sold real estate. Three were connected with medical journals. One was an agent for drugs. One for books. One preached. One was in the patent medicine business. Two were farmers. One a manufacturer. Two gave massage treatment. One sawed wood, and subsequently suicided. Twelve gave up in disgust, and one never tried practice at all. Twenty-nine graduates only in 100 exclusively devoted themselves to medicine, and of these 11 associated themselves with other practitioners, and in many cases fell heir to their practice."

AN ARMY MEDICAL BOARD.

An Army Medical Board will be in session in New York City, N. Y., during October, 1891, for the examination of candidates for appointment in the Medical Corps of the United States Army, to fill existing vacancies.

Persons desiring to present themselves for examination by the board will make application to the Secretary of War, before September 15, 1891, for the necessary invitation, stating the date and place of birth, the place and State of permanent residence, the fact of American citizenship, the name of the medical college from whence they were graduated, and a record of service in hospital, if any, from the authorities thereof. The application should be accompanied by certificates based on personal knowledge, from at least two physicians of repute, as to professional standing, character, and moral habits. The candidate must be between 21 and 28 years of age, and a graduate from a Regular Medical College, as evidence of which, his Diploma must be submitted to the Board.

Further information regarding the examinations may be obtained by addressing the Surgeon General U. S. Army, Washington, D. C.

C. Sutherland,
Surgeon General U. S. Army.

INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

Telegraphic advices from London, under the date of Aug. 10, state that the seventh annual session of the International Congress of Hygiene and Demography opened in St. James' Hall, in the afternoon of that date. At an early hour the royal yacht left Portsmouth for Cowes, Isle of Wight, the object of the voyage being to bring to England the Prince of Wales, who was to preside at the Congress. His Highness arrived in London on good time and when he called the Congress to order there were 2,300 delegates present in the hall. Among the more prominent delegates in attendance were Professor Pasteur, of Paris, and Professor Koch, of Berlin. Many of the leading doctors and scientists of Europe will take part in the deliberations.

When the Prince of Wales arose to make his address of welcome he was heartily cheered. He discoursed understandingly on hygiene and said that the people were exposed to many sources of danger, owing to the existing state of factories, from overcrowding and from the unsanitary condition of towns. He was happy to say however, that statistics showed a marked improvement in this direction which might safely be taken as an earnest of the increased good to be accomplished by scientists in the future.

Among the many important subjects to be discussed is the general question of the means to be employed for preventing the spread of epidemic disease from country to country, which will be introduced by Surgeon General J. M. Cunningham, of England.

CONSANGUINITY, CONCEPTION, AND MALFORMATIONS.

Has the condition of the male parent, when begetting, any distinct influence on the offspring? A case related by M. Guéniot at the Paris Académie de Médecine would seem to fevor the theory that there is such an influence; but in this case consanguinity must be also taken into account. A woman married her nephew, a man three years younger than herself and for long ad-

dicted to absinthism and other forms of intemperance. She declared that he was always partially drunk when she admitted his embraces. The curse of the mediæval Melusina fell on the offspring: seven children were born, of which only one survived and several were deformed. The last child was of great size, causing labor to be difficult. It was anencephalous, with six fingers on each hand and six toes on each foot; the external genitals were absent. Two large serous cysts occupied the liver, and were the cause of the great bulk of the child. Considering how some of the most minute physical peculiarities and some of the most subtle mental characteristics are transmitted from father to child, it is not wonderful that the offspring may be influenced by the state of its sire when impregnating its mother. The influence is probably indirect in a case like the above. No doubt absinthism and ordinary intemperance affect the nutrition of all cells and fluids, spermatic included. The nervous condition of the mother may be unfavorable under the circumstances. The share of consanguinity in this case is doubtful. Recent researches tend to show that unions of consanguinity may keep up or intensify diseases and malformations already in the family, but there is no evidence that they cause new maladies and deformities.—*Brit. Med. Jour.*

THE MEDICO-LEGAL ASPECT OF THE JACK-THE-RIPPER CASE.

Much interest has been excited during the past week over the trial of an alleged "Jack-the-Ripper." The circumstances of the crime have been made very widely known. A woman of the lowest class was found one morning murdered and mutilated in an East Side resort. The person with whom she slept that night had disappeared, but the police apparently feeling it a matter of pride to capture some one, secured a half-witted Algerian who had slept in a room in the same house on the same night. In the course of time a very pretty web of circumstantial evidence was woven about him. The most important of these circumstances was the fact that stains of blood were found on the Algerian's clothes, on the floor or door between the rooms, and of course on the bed or clothes of the murdered woman. It was asserted by the medical experts that these stains all were mingled with matter which came from the small intestine, and that this chylous material came from a meal that was in the same stage of digestion. This identity of the different blood and fæcal stains, so far as we can make out from the reports, was based on the fact that tyrosin, and perhaps other products of pancreatic digestion, were found in them all, as well as in the scrapings from the prisoner's nails. Tyrosin is a substance which crystallizes usually in the shape of fine needles, grouped as radiated stars. In this respect it resembles somewhat hypoxanthin. It reacts to certain tests; but other bodies, such as sarkin, react in a similar way. Tyrosin is found in the urine in certain diseases. Altogether it would seem a little hazardous to convict a man on the microscopically established identity of minute collections of blood and intestinal matter. But the lawyers for the prosecution were skilful and the police had collected a voluminous mass of minor evidence, mostly from criminals. The result was a conviction of murder in the second degree. The medico-legal points raised were very interesting, and we do not doubt that the evidence was given most conscientiously. It is to be hoped, however, that it will be submitted some time to the judgment of the profession. At present there seems to be a feeling that the accused was made a scape-goat for the reputation of the Police Department.—*Record.*

A CHEMICAL ROMANCE.

When *Al-Embic* uncle's wife died, he sent a *Nit-rate* telegram to his sister *An-Alyze* asking her to join him on a short trip with the *Anti-mony* they received. A week later they started from the old homestead and let their colored nurse *Chlo-ride* as far as the next town with them, where they embarked on a steamer. As they passed down the beautiful river on the banks of which *Flowers of Sulphur* were in full bloom, they saw a crowd of little darkies taking a *Sand-Bath*, and they remembered this particularly as there was no other *Nigro-sine* during the entire trip. A black bird that flew past the vessel's bow was pronounced to be an eagle by one of the gentlemen on deck, but a sailor overhearing this, remarked: "That's not an eagle, that's a *Chro-mate.*" This unsolicited *Retort* did not please the gentleman, so he descended the companionway to take a *Water-Bath.*

In the captain's cabin quite a party had collected, and an animated mythological discussion was in progress as to the year, and of what, the goddess *Io-dide.* A medical student present said he had forgotten the date, but that there was no doubt that *Io-dide* of Arsenic. Drinks were then

passed, and the medical student took some *Schiedam-Schnapps* with water, which he said was a *Standard-Solution* known scientifically as *Hydro-gen*, and that he did not mind if he took another, *Ether*. His German friend, a doctor with green spectacles, whose name was *Amyl*, when asked if he would take one too, answered,—"Ich *Sulphur* dammt sein" if ever he'd let it pass.

This nearly resulted in a fight between the German and a minister present, who objected to the use of such *Sulphurous* language. The captain, recognizing the peculiar and *Specific Gravity* of the occasion, restored order by taking a club from the wall and blandly remarking, "No *Phos-phor-us*, gentlemen, if you please."

A gay crowd of young people had collected on deck, and the gallant captain showed much attention to the ladies, of whom there were quite a number. He let them look at *Mercury* through his *Beeker-Glasses*, showed them how he took soundings with a *Test-tube* and made himself generally agreeable. There seemed to be a great *Affinity* between himself and a girl nicknamed *Sili-Cato*, because she giggled every time she saw him. This so disgusted *Ani-Line* that she told *Sali-Cylic* that neither she, nor *Ga-Lena*, nor her sister *Ethyl*, would ever speak to her again. Everything went well until the German doctor's mother in-law, a regular *Tartar-ate* too much of the *Platinum-sponge* cake, served with the *Is-in-glass*, which precipitated her upon the *Fluor-in* an unconscious condition. This accident made the *Prussian-Blue*, but as he had carefully *Red Prussiate* before he started out on the trip, and had taken his medicine chest along, he was equal to the occasion, and soon able to announce to the anxious company that the old lady's illness was nothing serious, a mere fit of indigestion caused by her eating too much *Sauer-Stoff*. He further ventured the good advice that if people generally *Lead* a more regular life, and instead of stuffing at dinner would only *Dyn-a-mite*, the world would be healthier.

He said the word *Pig-ment* an animal, but in its metaphorical sense should apply exclusively to man. He supposed, however, it was no use preaching to the generality of man, for if born an ox, an *Ox-y-dize*. One of the passengers, who evidently felt himself hit by these remarks, said sotto voce, to his neighbor, that there was unnecessary *Caus-ticity* in the doctor's talk, a great deal of which was a transparent *Lye*. After the dinner, music was in order, and another German brought out a cornet, which he called his *Blow-pipe* and produced a composition *Bi-sulphate* followed by another *Bi-phosphate*.

Both of these compositions were very appropriate for the occasion, being rhapsodies by the sea, and hence fitly called studies in *Ultra-marine* by the learned doctor.

Then riddles and conundrums were proposed, the first one being, "Why are *Clay* and *Phosphorus* identical," the answer being "Because it is *A-luminous* material."

The next one was, "Why is the feeding of a bull at midnight a chemical operation?" Answer, "Because it is giving an *Ox-a-late* meal." A lawyer said that in so far as this could only apply to an ox, and not to a cow, he did not consider it a *Case-in* point.

The next conundrum was proposed by the medical student, and was as follows: "How can we all be made happy?" To which the doctor responded that he had a never *Feh-ling-Solution* for this question, which he would now have served to the guests in the form of champagne.

A crusty chap who did not appreciate the humor in all this light talk, remarked that he thought an habitual punster the greatest *Bor-on* earth, and that he would not be surprised to hear an *As-say* smarter things than that, indeed a *Copper-as* if it could talk. Fortunately the irascible German doctor did not overhear these ill-natured remarks, or there might have been a *Par-af-fine* black eyes in that company.

After all this fun the talk assumed a graver vein, and the festivities wound up, as will my story, with a few appropriate remarks by the minister. He said:

"When a mere child, I once asked a minister whether a bad man could ever go to Heaven. He replied that in virtue or *In-cin-e-rated* man's chances equal, providing reform took place in time; in other words, he did not think early *Cin-a-bar* to glory.

"Oh, my friends," he concluded, "we are none of us pure *Gold*, none without an *Alloy* of *Baser-Metals*, but, dear friends, if in the darkness of our sin, we will only *Cry-o-lite*, it will generally come to us.

"I once knew a man who led a very wicked life until his friends all said 'old *Nick-el* get him' but the *Dross* fell from his soul at last; and often after I heard his own *Tung-state* the story of his reform. My friends, all the world's a stage, and we are but actors on it. There are lives, pure, honest, undramatic, others *Ar-senic*, *Ac-id* were; sometimes even the *end* of such lives *Ar-senical* effects."—*V. G. Bee in Western Druggist.*

Clinical Lecture.

SURGERY OF THE LUNGS.

BY DR. KRECKE,

OF THE MEDICAL FACULTY OF MUNICH, GERMANY.

Gentlemen:—Koch's recent discoveries have added new interest to the subject of surgery of the lungs; permit me, therefore, to detail some personal experiences, which, I trust, will be of both interest and value to you. The most of my experiments were made at the Erlanger Clinic of Professor Heineke. Allow me, however, at the outset of this lecture to state that, owing to certain complications, the ultimate success of the treatments was far from satisfactory; nevertheless, I consider the cases instructive as showing the general indications for, as well as the value of surgery of the lungs. Regarding the various indications for surgical treatment, I shall but briefly touch on this phase of the subject.

Surgery of the lungs may be considered from two points of view: either with reference to the nature of the surgical interference or with reference to the existing pulmonary disease.

Regarding the different pulmonary operations, we have but two at our command, namely, pneumotomy, and pneumectomy. Let me here say that I only regard such procedures surgical, as may be undertaken with the knife, while such as injections, cauterizing, and hypodermic medication, I class in the field of internal medicine. Of the above-named operations, pneumectomy can only be thought of when we have morbid growths of the lungs, or the like, to deal with. Although various experiments upon animals have been made, relative to the possibility of removing portions of the lungs, in all probability these procedures will never be tried upon the human being. Only in cases where the foreign growth has sharply defined limits can a removal of the affected portion of the lung be considered justifiable, and the well-known successful case of Kronlein illustrates a triumph of surgical technic. A similar case operated upon by Weinlechner resulted unfortunately.

Apart from these isolated cases of pneumectomy, indicated by the presence of morbid growths, the only rational surgical procedure in diseases of the lungs may be regarded as pneumotomy, and we will do best, therefore, if we discuss the subject before us from the standpoint of the disease, and not the operation. The disease which most imperatively demands surgical treatment is *pulmonary gangrene*. There is scarcely a practitioner who has not at some time met with the loathsome symptomatic picture of this disease, accompanied with its foul discharges, which are even unbearable to the sufferer's attendants. A spontaneous healing of gangrene of the lungs is almost unknown, and the dangers accompanying the disease are numerous and very great. Abscess of the brain is a frequent complication, other portions of the lungs may become infected, and all this apart from the great weakening of the patient owing to the constant drain on the system. In such cases every one will agree that if the seat of the trouble can be accurately determined, careful opening and drainage are certainly indicated. But the difficulty in treatment is chiefly due to the lack of an exact diagnosis. Here it would seem advisable to make a distinction between gangrene accompanied by a purulent pleurisy and that without. Empyema, of course, always necessitates the opening of the pleural cavity. If, in such a case, the presence of a gangrenous patch is suspected it is well to examine the lung by touch as extensively as possible, in order to determine the existence of any soft or nodulated areas. These areas, when found, should be treated with the thermo-cautery and freely opened. It is, perhaps, a wise procedure to always examine the lungs for gangrene in every case of em-

pyema.

The following instance comes very forcibly to my mind. I had operated for a case of empyema which had occurred after pneumonia, but the existing fever did not fall, as it generally does, in consequence of the operative procedure. I sought in vain for some adequate reason for this unfavorable symptom, but found none until several days later while changing the dressing of the wound in the thorax, I noticed a blackish mass protruding from the opening. It was easily removed and proved to be a portion of the lung in a gangrenous condition. After this the fever soon disappeared, the wound closed,and the patient convalesced. In another case which came under my observation some time later, the same elevation of temperature in spite of the operation was noticed, and—profiting by my former experience—I searched for gangrene, and found it. The case was a man, about twenty years old, who, in consequence of having swallowed some lye, developed a stricture of the œsophagus which was impassible. After bougies had been vainly used for a long period, symptoms of gangrene of the lungs began to manifest themselves, and at the same time the patient developed a purulent right-sided pleuritis. It was in a half-starved, frightfully ill, and truly pitiable condition that the patient was brought to this clinic for operation. The absolute hopelessness offered by any internal treatment was very apparent, and therefore, in spite of the patient's almost moribund condition, a speedy and thorough surgical operation was decided upon by Professor Heineke. First, external œsophagotomy was performed and a rubber tube introduced into the stomach; then, the empyema was relieved by resection of the ribs; and then, a careful digital examination was made for gangrene, and the disease found at the lower lobe and the gangrenous portion removed. The cavity was about the size of a hen's egg. The operation was conducted with the patient only partly narcotized, and he did not survive the shock, dying six hours later, apparently from heart failure.

In cases of gangrene of the lung occurring without empyema, it is most difficult to locate the disease. The only diagnostic method at all positive, is exploratory puncture. In such cases the operator should not be discouraged even although many repeated punctures are necessary. When the gangrenous portion has been found it will be recognized by the presence of portions of gangrenous tissue, foul discharges or perhaps even only by the presence of fœtid air.

In one case of this description I punctured fifteen times before being able to locate the disease. The patient was a girl, fifteen years old, who also had a stricture of the œsophagus, the result of swallowing lye. After many futile efforts had been made to pass a bougie, the patient was brought to the surgical clinic, and Dr. Heineke performed external œsophagotomy, introducing a slender catheter into the stomach. The next day a large catheter was introduced, and shortly after a rubber tube of considerable size.

It was truly a pleasure to see how rapidly the starving child gained strength. Convalescence was, however, soon disturbed by the appearing of symptoms which pointed to an existing communication between the trachea and œsophagus, and the outlook became still more serious, when, accompanied with fever, typical gangrenous expectoration appeared. Over a dozen punctures were made without any result; finally, a puncture resulted in finding a blackish discharge which had the typical, penetrating odor of gangrene. Excision of the ribs was performed, and we were able to remove the entire gangrenous portion of the lung. A tampon of iodoform gauze inserted into the cavity completed the operation. Again the child convalesced with astonishing rapidity; but it was not long before an elevated temperature again made its appearance, caused by the development of a left-sided serous pleuritis. This was punctured several times, but the child gradually sank and died soon after.

At the autopsy, besides the communication between trachea and œsophagus, several abscesses were found in the lung. The gangrenous cavity which had been operated upon was in the process of healing. Undoubtedly, the sole cause of the non-success of all our therapeutic measures was a continual re-infection through the tracheo-œsophagal fistula. While this case resulted fatally, it nevertheless showed, unquestionably, the beneficial results obtainable by surgical interference in cases of gangrene of the lung, and, therefore, that pneumotomy must be looked upon as a most valuable as well as a trustworthy operation. Successful cases in the hands of other operators substantiate this assertion. Slawyk reports 14 cases with 8 recoveries, and Seitz 19 cases with 4 recoveries and 4 improvements, 11 having died. It must be remembered, however, that many of the fatal cases were not the result of a failure of the operation, but—as in my own cases—the result of other sequellæ.

The prognosis of gangrene of the lungs is so hopeless, that any operative procedure

that offers even the slighest hope of recovery, should be eagerly resorted to.

Regarding surgical interference in *abscesses of the lungs*, the same can be said regarding gangrene. The indication is that they should be opened; and further that this course should be pursued, although the abscess has previously opened spontaneously into one of the bronchi. According to Seitz, out of 11 cases 5 recovered and Slawyk's statistics show that out of 13 cases only 3 resulted favorably. I, personally, have had no experience with the surgical treatment of pulmonary abscesses, and, therefore, have not statistics to offer. In the only case coming under my observation, while the presence of an abscess was positively diagnosed, I was unable, even after repeated punctures to locate its seat, and we must, therefore, overlook this case.

An effort has even been made to treat bronchi-ectasis by surgical means, but the majority of authorities on the subject have dismissed the feasibility of the operation. Bronchi-ectases do not usually exist singly, but are multiple, and therefore the opening of a single cavity can be but of very questionable benefit to the patient. If the presence of only one bronchi-ectasis cavity were indisputably diagnosed, surgical means would seem justifiable.

I once had the opportunity of attempting a surgical operation in a case of bronchi-ectasis, but unfortunately was unsuccessful. The case was brought to this clinic for the purpose of having an operation performed for empyema. The patient was a man, forty-eight years old, who shortly before had been admitted to the Hospital in a deeply cyanosed condition. The only history obtainable from him was that he had been suffering from pulmonary trouble for a long time, and that a few days previously he had been attacked with severe fever. A very small area of dulness was found, from which some pus was evacuated with the exploring needle. Several punctures in other locations revealed nothing. Owing to the very small area of dulness, the diagnosis of empyema seemed to very doubtful, still I felt justified in opening the thorax by resection of the ribs. Having done this, however, I found the pleural cavity empty, and the immediate appearance of a pneumothorax made the examination of the lung most difficult. Several punctures of the lung were made, but they revealed nothing, and so I was forced to conclude the fruitless operation. The patient sank rapidly and died within a few hours. The subsequent autopsy revealed a large bronchi-ectasis in the lower lobe of the left lung, at the lower extremity of which was a suppurating area corresponding with the area of dulness which had been found, and from which pus had been obtained. In my own opinion, I do not believe that the man would have reaped the least possible benefit from an opening of this cavity.

It is very evident that the justifiability of operative procedures in this class of cases is open to grave objections, and only the more so when it is considered that a lethal termination of the case by the development of pneumo-thorax is considerably hastened. I must confess, that in the case just mentioned, I hesitated considerably, having in mind the deep cyanosis of the patient, and the dyspnœa. Had the case been treated therapeutically, and carefully watched, the result might have been different, but the condition of the patient seemed to brook of no delay in decision.

We are finally brought to the consideration of the surgical treatment of *tubercular cavities*. Our inability to cope with the general infection, has almost put such procedures out of the question, and all efforts in this direction have been apparently futile. So, for instance, in six cases operated upon by Cérenville, five died, and in the remaining case the result was doubtful. Only in such cases where severe symptoms, such as high fever, etc., can positively be shown to originate from a single cavity, can the thought of a surgical interference be contemplated. This condition of affairs is clearly elucidated in the history of the following case, operated upon by me a few months ago. The case was referred to me through the kindness of Professor Schech.

The patient was a tuberculous man, 33 years old, in whom evidences of a cavity in the lower lobe of the right lung had gradually appeared. Simultaneously the patient developed a severe septic fever with frequent chills, which was presumably caused by the cavity. The operation was performed without difficulty. The lobes were found firmly adherent to each other. By means of a blunt pincette an opening was made through the lung tissue into the cavity, which latter was packed with iodoform gauze, and an antiseptic dressing applied. After the operation the fever fell immediately, and the patient seemed much improved. The discharge from the cavity was considerable. All went well for some time and the patient

was even able to leave his bed for hours at a time, when suddenly severe hæmoptysis occurred and the patient died.

In such cases, as has been said, surgical interference is indicated. We can only regret that we have not yet had an opportunity to test the simultaneous action of Koch's tuberculin in conjunction with such operative procedures.

A few more words regarding the method of performing pneumotomy and the after treatment. In the cases cited the opening of the lung was always made with a blunt instrument. In deep lying cavities or gangrenous patches it is well to penetrate the lung tissue by means of the thermo-cautery. This was also the method adopted by Sonnenburg. Instead of dainage, a sterilized tampon should be used, preferably iodoform gauze. Irrigation can not be recommended, especially after the experience we have had in its use in empyema. It has frequently caused asphyxia, and at other times the penetrating of the liquid into the bronchi not infrequently gives rise to violent paroxysms of coughing, and besides this the subsequent discharge from the wound is increased instead of decreased.

Such, gentlemen, are the few experiences which it has been my privilege and pleasure to report to you. Let us only trust that they may have awakened sufficient interest in some of you, to encourage you to broaden this domain of surgery by your personal study and zealous investigations.

COMMUNICATIONS.

DIAGNOSIS AND TREATMENT OF CHRONIC ENDOMETRITIS, WITH FOUR ILLUSTRATIVE CASES.

BY HOMER C. BLOOM, M. D.,
PHILADELPHIA.

After a most careful study into the histories of some recent cases of general chronic endometritis, I have no hesitation in affirming that it is a disease whose treatment is more at fault than that of any other from which women suffer; and in fact, not only the treatment is at fault, but as frequently the diagnosis, causation and everything connected with the successful management of this condition.

My object in writing this article, is to give some of the practical points as gleaned from a series of cases, the notes of which I have carefully preserved, remembering that however conscientious the general practitioner may be, he has not the time to devote himself to the careful study of special diseases.

The first case in this series was a married woman, thirty-seven years of age, seven pregnancies—five at full term and two miscarriages at the third month—since which time she had been ill. She complained of the following symptoms: Sensation of dragging of the lumbo-sacral region, bearing down pain in the pelvis, menorrhagia, with gastric disturbance, pain and pressure upon the top of the head, and muco-purulent leucorrhœa, with flushes and constipation, pain and tenderness of the mammary glands, sleeplessness, mental depression, showing marked symptoms referable to the general nervous system.

Upon digital examination, the first abnormal condition which attracted attention was the prolapsed and tender uterus, which was enlarged, felt soft and readily escaped from touch. Aside from this prolapsed condition which was due to its weight, there was no displacement, neither was there any adhesions, as it was perfectly mobile, the cervix was patulous and soft as in pregnancy. The sound passed to a depth greater than normal, i. e., three inches plus, and came in contact with irregularities of the mucus membrane—to the touch as transmitted by the sound—the fundus felt soft and velvety, there was considerable hæmorrhage upon the withdrawal of the sound. The speculum showed the muco-purulent discharge tinged with blood escaping from the os.

Before considering this case further, it is worth while to consider the etiology of this important lesion.

Constitutional diseases are prominent causative factors. Strumous diathesis, general debility, faulty hygiene and nervous exhaustion; gonorrhœa and syphilis are potent causes and give rise to most disasterous complications; passive congestion from displacement, badly fitting pessaries, excessive venery, imprudence at the menstrual period, improper attention during parturition or lying-in period, abnormalities of the canal with stenosis, neglected lesions following child-birth. Also abortion, a most frequent cause. In the present case, what is likely to have been the cause of her condition? Referring to her history, we find she has not been well since her last pregnancy, which resulted in a miscarriage at the third month.

Following this miscarriage, she had a fœtid discharge per vaginum, passing shreds of decomposed tissue.

We know that in the third month of gestation, the delivery of the placenta often presents difficulties less frequently met with at a more advanced stage of pregnancy, or at an earlier period, when both are expelled together. Evidently in this case there was retention of placental issue, which no doubt accounts for her condition.

From a pathological standpoint, we have in general chronic endometritis hypertrophy of the mucus membrane; the most simple is glandular hypertrophy, resulting in a roughened papillary surface. We also have a form in which the surface is studded with fungoid growths, the vessels becoming dilated and enlarged, and the patient's health directly impaired by loss of blood.

Arriving at a positive diagnosis in general chronic endometritis as a separate disease, we must differentiate from new growths benign or malignant, growing within or upon the mucus membrane. Microscopical examination of the endometrial discharge will clear up all doubtful cases. This brings us to the treatment as carried out in this case. The local treatment consisted in exposing the cervix through a speculum, catching the anterior lip with a tenaculum, making gentle traction, straightening and steadying the uterus, so that the exact course of the uterine canal was easily found by passing the sound; in like manner the dull, blunt wire curette was passed, carefully but boldly over all the uterine surface where the least roughness existed; this was done antiseptically, and after moderate dilitation of the cervical canal and the characteristic granular discharge which under the finger feels rough and friable, came away with the curette.

The mucus which remained was sucked out of the canal by the uterine syringe, and wiped dry by a cotton-covered applicator. This is often a difficult procedure, owing to its tenacious character. An alkali, as a solution of bicarbonate of soda, will aid very materially in its removal. And the thorough removal of all uterine secretions is one of the most important steps in the treatment of these cases, previous to the introduction of your remedial agent.

An intra-uterine injection of ten minims equal parts of a saturated solution of iodine and crystals of carbolic acid was carried up to the fundus, through a long-nozzled, glass-barreled graduated syringe, injected gently and without force, placing a pledget of cotton under the cervix, preventing contact of medicine with the vagina. The surplus of this mixture usually flows back, if it does not pass the sound, and all that is left will likely come away.

This patient, as indeed all patients undergoing this local treatment, we advised to remain quiet for a few hours, and the same treatment was repeated once a week for the first three weeks, then the curetting was omitted, and the application of the iodine and carbolic acid was continued weekly for two months. There was considerable oozing of bloody serum from the uterus for several days after the curetting. Each succeeding menstrual period came on at the proper time; the flow less profuse, and with the addition of the constitutional treatment, which consisted in regulating the bowels with a saline mixture, tonics of iron, alternated with the compound syrup of hypophosphites, the patient was cured at the end of the fourth month, and is now perfectly well, six months after her discharge.

A very important question: Is there no danger in connection with this local treatment? Unhesitatingly, yes. The contra-indication for this treatment would be any inflammation, acute or sub-acute, surrounding the uterus; and this requires the most careful diagnosis, eliminating all complications present, and should there be found the least peri- or parametric inflammation complicating a given case, under no considerations use intra-uterine injections.

Case II.—An old lady aged 67, mother of twelve children, menopause at forty-five, has had a thin, serous, bloody, leucorrhœal discharge ever since the climacteric period, with great itching of the genitalia, flushes of heat with vertex pressure, all other symptoms nil. Upon physical examination, found shortening of the vagina due to age, the cervix was soft and patulous, uterus tender upon firm pressure, and had not undergone that atrophy which is physiological at her age. The uterus was larger than a normal uterus before the climacteric. The introduction of the sound gave great pain, and the endometrium was found to be roughened all over its surface. The sound measured three and a half inches; upon introducing the speculum, the characteristic discharge of a dirty, serous appearance was seen coming through the patulous os. This particular leucorrhœal discharge being present in almost all cases of pruritus vulva after the menopause.

Accounting for the causative factor in these senile cases, we must be governed by the history. Interrogating this patient, we

found her hygienic surroundings at the climacteric were not conducive to this physiological change. We are therefore led to suppose that from the fact of her being perfectly well up to this period, and giving birth to twelve children at full term, that the etiological conclusions would be faulty hygiene.

The treatment was curetting every week, followed by intra-uterine injections of fifteen minims equal parts of carbolic acid and glycerine. This was continued for four weeks, then the curetting was omitted and the intra-uterine injections continued every week for a period of six weeks, after which an intra-uterine injection once a month for three months completed the cure.

There was from the first treatment, marked improvement in the pruritus, and the uterus rapidly underwent that physiological change which is natural at this age; sound measuring at the last examination, one and a half inches.

The constitutional treatment in this case was simply regulating the bowels, and a salt-spoonful of chloride of ammonium, in a wine-glassful of water after each meal.

Case III.—This patient was twenty-one years of age, puberty at sixteen. Dysmenorrhœa; married two years; sterile; perfectly well until shortly after marriage; had not been well since. One week after marriage, commenced suffering with heat and burning in the vagina, aching and sense of distress in the perineum, frequent micturition, with a sensation of scalding. A profuse, purulent, mucus discharge from the vagina, great irritation of parts around the vulva.

These symptoms continued with more or less severity for three months, when there was an aggravation of all symptoms, with rigors, fever, nausea, vomiting, severe pain diffused all over the abdomen. She was compelled to give up and go to bed; suffered from a severe attack of peritonitis, as diagnosed by her physician. After twenty-one months of suffering, in which time there had been repeated attacks of pelvic peritonitis, with marked constitutional disturbances, we see a patient profoundly ill, anæmic, loss of flesh, nervous system greatly disturbed, pulse frequent, temperature varying from a degree to two degrees morning and evening, with sharp paroxysmal pain, which is circumscribed. She was able to point out the exact spot in the left ovarian region whence this pain started, and from where it radiated. There was great tenderness at this point. There was a decided dragging, heavy feeling in the lumbo-sacral region; vertigo, with pain and pressure on top of the head; dyspepsia, nausea, constipation, and flatulence, frequent micturition, with menstrual function regular in time, but profuse; the menorrhagia lasting ten days, and attended with cramp-like pains and the passing of clots. She had a mucopurulent leucorrhœa.

Upon physical examination I found the vagina somewhat shortened, cervix low down upon the floor of the pelvis pointing forwards, soft as in pregnancy. The uterus was large, tender upon pressure; body sharply anti-flexed. There was strong adhesion, and it was immobile. There was a hard, tender, irregular body in Douglas' pouch, which appeared to be attached to the uterus; and to the left in the post-uterine space was a circumscribed mass about the size of a small orange, fluctuating and very tender; and from the character of the pain excited by touch, ovarian; also felt a tumor somewhat elongated, movable, slightly fluctuating, not separable from the uterus; lying upon the left above the circumscribed mass, which was evidently the left tube in a state of chronic salpingitis.

I had here to deal with the resultant lesion of a specific cause, which probably lighted up at the commencement of her illness, acute ovaritis salpingitis and pelvic peritonitis.

The lesion which we are more particularly discussing in this paper is the general chronic endometritis which this patient suffered from. The greater number of cases of general chronic endometritis which have come under my observation, can be traced to parturition or arrest of post-parturia and post-menstrual involution, with gonorrhœa as the next most important etiological factor.

The treatment pursued in this case was entirely different from the previous cases mentioned. Intra-urine injections should never be used in cases similar to this, where there is the slightest indication of inflammation of the adnexa; the consequence of such treatment would be to re-kindle or light up a serious pelvic inflammation.

Both local and constitutional measures were carried out in this case. The constitutional treatment consisted in first regulating the bowels, one of the most important parts of the treatment of all uterine cases. She was given at first a saline, preferably sulphate of magnesia for a few weeks, and then a laxative pill; she was also put upon the four chlorides:

℞

Hydrarg-chloridi corrosivi.....gr. j.
Liquor arsenici chloridi.....f3.
Tr. ferri chloridi.....
Acid hydrochloric diluti, aa.....f5iv.

Syr. simplicis.....f℥iij.
Aquæ qs ad.....f℥vj.
M. Sig. A dessert-spoonful well diluted with water, three times a day after each meal.

This medicine was given for six weeks and then omitted for a month, and again taken after six weeks, and continued in this manner for six months, with the additional prescription:

℞ Ergot flu. ext.
Tr. nucis vomica, aa.....f℥j.
M. Sig. 40 drops in water before meals three times a day.

This last prescription is very efficient in many of these cases where the uterus is enlarged and tender, complicated by menorrhagia.

She was ordered plenty of good nourishing food; with this treatment her general condition improved.

The local treatment consisted in first removing the secretions from the cervix, and applying tincture of iodine; also to the exudate and entire vault of the vagina every third day; once a week a tampon of antiseptic wool saturated with glycerole of tannin was placed against the cervix, allowed to remain twelve hours and removed, and directed to take a hot water douche. These douches were also ordered night and morning regularly, and to use not less than a gallon of water and to take them through the Gordon irrigator attached to the fountain syringe, the very best method by which the patient herself can successfully employ hot water douches. After six months she is much better, increased in flesh, strength and nervous condition, and some improvement in her local symptoms. At the same time this gain cannot be permanent with the diseased condition which evidently exists upon the left side. When this patient can make up her mind to have something permanent done, it will be necessary to remove the left tube and ovary; in cases of a specific origin it is always better to remove both appendages; even after salpovectomy your patient will not be cured until the endometritis is treated. It is the careful after-local treatment in many of these cases which give such brilliant results, the neglect of which often causes unkind criticism of our most skilled surgeons. After a practical study and analysis of a large number of cases which were operated upon for specific disease of the appendages, I have found months afterwards, in a great majority of these cases, chronic endometritis and the symptoms which belong to this lesion.

Case IV.—The patient, a lady of splendid physique, married at twenty-three years of age, and had her first child two years later. Her labor was tedious, but her recovery was satisfactory. When her child was two years old she became pregnant again, and miscarried at the third month. She has had in the fourteen years since her marriage, four miscarriages, and all of them at the second month. She suffered from menorrhagia, pain in the lumbo-sacral region, pelvic tenesmus, flushes, vertigo, profuse, mucopurulent leucorrhœa and general depression.

She was first treated five years ago for endometritis; this gave her some relief, however only temporary, and she was repeatedly treated for the endometritis, but her old symptoms would return again and again. The physical signs proved this to be a typical case of bi-lateral laceration of the cervix uteri. In view of this condition, restoration of the cervix was proposed in the hope that the operation would give her permanent relief; but not until the endometritis was curetted and carbolic acid and iodine was applied once a week for a month, at the end of which time the endometritis was apparently cured; but not the etiological factor upon which it depended—the injured cervix—the operation for its restoration was performed. The case progressed nicely, union was complete, and one year afterwards there has been no return of the endometritis, nor any of the former symptoms.

From my own personal experience, I can safely say in those cases of trachelorrhaphy, proceeded by thorough treatment of the uterine cavity, have been remarkedly successful, and it may just be here why Dr. Emmet's great boon to suffering woman is falling into undeserved disrepute, simply from want of care upon our part in the proper and successful management of these cases preceding the operation.

I have purposely selected these four cases out of the last series of forty cases, as being typical of the most prominent assignable causes in this the most important lesion from which women suffer. Probably the local treatment as practiced in these cases might lead one to suppose that we are dogmatic enough to think there is no other remedial measures by which we can reach the same end. I wish to say at this time, a series of cases of this particular lesion is being treated by the application of ichthyol, and I hope in a subsequent paper to prove the great value of this therapeutic agent in all diseased conditions of the cervical and endometrial membrane.

THE USE OF COLLODION AND RUBBER ADHESIVE PLASTER IN SURGICAL DRESSINGS. *

BY W. J. CHENOWETH, M. D.

DECATUR, ILL.

The remedy last used, preceding a cure, has popularized many ointments, salves, and liniments, and has given confidence in blue yarn strings tied around the neck, bags of sulphur hung across the chest, and to tincture of arnica. And we may rely on other remedies quite as useless as any of these, however sceptical we may be of them. Hence in presenting the claims of Rubber Adhesive Plaster, and of Collodion, both of which are in general use, but not as extensive use, as I think their merits demand, I may be governed by the *post hoc propter hoc* method of reasoning, but expect to present such suggestions only as if wrong, may be disproved by trial.

Calling attention to a few cases where these remedies may be employed advantageously will suggest others.

Where a roller bandage can be applied with benefit the rubber plaster will usually do better. It will relieve in lumbago, intercostal neuralgia, pleurodynia, strains and fractures of muscles, torticollis, fractured ribs, ulcers of the leg (whether from varicose veins or from other cause.) It is invaluable in synovitis, and in fractures of the femur, where extension is demanded. Its capacity to relieve is sometimes limited by inability to apply it. But in all cases the method of its application is the measure of its success. This can be illustrated by treating a fractured rib, if well applied, relief is obtained promptly, if poorly, it will not relieve. The chest being exposed, one end of the strip of plaster about two inches wide and twelve inches long, is applied to the back near the spinous processes, or on the front part of the chest near the sternum, commencing a short distance below the fracture, and being firmly held by the patient or by an assistant, the other end is carried over the chest and drawn as tightly as can be done without tearing. Other pieces, of the same width and length, and adjusted like the first, each slightly overlapping the one below, should be applied until as much above as below the point of fracture.

The little knowledge of the value of rubber plaster in the possession of certain members of the profession, can be illustrated by a case which fell under my notice recently. Called to see a lady who had been kept in bed for more than a month, because of an ulcer over the tibia, for which some kind of an ointment had been prescribed. The application of rubber adhesive plaster was advised so that she might secure necessary exercise by walking. Refusing at first she finally consented. After covering the leg from below the sore to some distance above it with plaster drawn as tightly as possible (a small piece of borated cotton having been placed over the sore and covered with the plaster,) and applying a roller bandage, to be sure that the rubber would not become loose, she walked across the room with ease. After about a week she received a message from her late attending physician, expressing great surprise that any doctor should apply a bandage as I had done, and advised her to cut a hole through the bandage over the sore, if I still persisted in having her wear it. The hole was not cut, the dressing was continued, the woman got well.

It goes without saying that in long and deep wounds, there has not been anything discovered which can absolutely supply the place of the suture. The success of treatment in such cases depends on obtaining close co-aptation of the parts in all of the divided tissues. But in superficial wounds, and in all wounds where the deep parts cannot be accurately approximated with sutures, there is no better dressing than collodion applied over cheese-cloth. In certain injuries such as crushed fingers, it is better to use borated cotton as it will prevent the contraction of the collodion from interfering with the circulation of the parts.

In injuries of the face, where it is desirable to avoid scars, dressings of cheese-cloth and collodion are preferable. Since commencing this article I saw a boy, with an ugly cut through the lower lip caused by a base-ball club. The wound being diagonal was dressed with difficulty, but the stitches were avoided by placing a narrow piece of cheese-cloth over the lip and covering it with collodion, and after it was dry enough to admit of tension, drawn tightly and the cloth twisted and placed on the cheek. The parts were closely approximated and healed with the slightest show of a scar.

After stitches have been applied in an operation for hare-lip small pieces of cotton batting can be placed over the lip, on each side of the line of the cut, and the cheese-cloth and collodion applied to one cheek and, when dry, stretched over the lip and fastened

* Read before the Illinois State Medical Society, May 21, 1891.

to the other cheek, the parts will be immovable, and when we wish, the cheese-cloth can be cut over the batting and lifted off the lip. The sutures can be removed and the cheese-cloth and the collodion applied over the first dressing and may be depended on to hold the parts in apposition.

This is one of the best possible dressings after removal of tumors from the breast. About ten years ago a tumor was removed from the breast of a lady forty-five years of age, by one of the best surgeons in the west, an epithelial growth being removed from the lip at the time. The lip healed and but a small scar marked the place of its growth. But the tumor returned after a short time. Not being convenient for the patient to visit the surgeon who had done the operation, I was asked to remove the growth. It was now about the size of a goose egg. After removal it was found necessary to take several stitches to hold the parts together, over and between them the cheese-cloth and collodion was placed; and drawn as tightly as possible. The dressing was not removed until the parts were entirely healed. Union took place by the first intention, and up to this time there has not been a return of the trouble. Whether the dressing had anything to do in preventing it I cannot say, but believe that it had. I have used the same dressing in the removal of mammary tumors since that time, but instead of tying the stitches and placing the collodion dressing over them the parts are drawn together with thread and held until the dressing is dry, the thread is then removed and the parts left with the dressing only.

After the sutures have been applied in an abdominal section the line of the incision is covered with antiseptic cotton and over this the collodion dressing, the rubber bandage, and roller being applied in the usual way.

In wounds of the scalp this dressing is easily applied and will hold the divided parts better than any other, and until the growth of hair removes it, by which time the parts will have healed.

Success in using the collodion, as was said of the plaster, depends on the manner in which it is applied. The parts should be brought close together and held until the dressing is dry, and being antiseptic and germicidal, may be relied on as effective.

The collodion must be of good quality, which can only be assured by making it yourself. The gun cotton must be of a kind that will dissolve in common commercial sulphuric ether in sufficient quantity to cause the liquid to be nearly of the consistence of glycerine and it should have a slightly yellow appearance.

Without intending to make invidious distinction amongst the many samples of collodion on the market, I have used with satisfaction Charles Pfeister's, Billing & Clapp's, and Anthony's.

VOMITING OF PREGNANCY; ITS ETIOLOGY AND TREATMENT.[1]

BY F. BLUME, M. D.,
ALLEGHENY, PA.

Pregnancy, as a rule, is complicated with a variety of disorders, which, though in many instances causing much discomfort, are termed physiological as long as they are not associated with serious disturbances of the organism. Derangements of the gastro-intestinal canal, nausea and vomiting, to the consideration of which I invite your attention to-night, are such a regular occurrence during the early period of pregnancy, that experienced women consider them as positive signs of conception.

The so-called morning-sickness—nausea and vomiting early in the morning, or even after meals during the first few months of gestation—have, in the large majority of cases, no effect either upon the course of pregnancy or upon the health of women. Although the ordinary morning-sickness sometimes persists during the whole period of pregnancy, it remains endurable, causing the patient rather annoyance than injury. There are intermissions, either spontaneously or the consequence of some treatment, the digestive functions remain more or less normal, and the vitality of the patient is not essentially impaired. In some, fortunately very rare instances, however, nausea and vomiting become incessant and uncontrollable, the stomach rejects everything, the patient grows weaker till the most extreme degree of exhaustion is reached, and death from starvation threatens.

The onset of this grave form of the affection is gradual, and does not differ in character from the usual morning-sickness. But soon the nausea becomes more intense, the vomiting more frequent. The ejected matter consists of food, mucus and bile. The appetite is more or less impaired or perverted; the thirst is excessive; constipation is more

[1] Read before the Allegheny County Medical Society, June 16, 1891.

frequent than diarrhœa; the urine is scanty, concentrated and contains albumen and casts. The pulse grows small and rapid, the temperature rises and continued fever develops.

With the progress of the disease the condition of the patient becomes more and more alarming. The nausea is almost constant, adding greatly to the discomfort of the woman. The efforts at vomiting are accompanied by violent retching and pain, not the smallest amount of food or drink is retained by the rebellious stomach, the smell, even the thought of nourishment, or the slightest movement of the patient, induces an attack. The vomited matter is finally mixed with blood. The thirst is tormenting, the throat and mouth are dry, the tongue brownish, the breath fetid, the abdomen tympanitic. The consequences of this continued suffering soon become very pronounced by the marked alteration of the features, the extreme emaciation and the profound depression of the patient. Shortly before life ends vomiting ceases and coma supervenes.

Cases of persistent vomiting, which terminate fatally, are certainly very rare. Even after the application of various methods of treatment has failed to influence the course of the disease, and while the induction of abortion was earnestly considered, the patients have recovered spontaneously and have gone to full term, as I have seen in the only instance of this grave disorder which has come under my observation.

There is considerable diversity of opinion as to the causes which may incite hyperemesis, and, in spite of numerous theories and hypotheses, the etiology of this disorder is by no means clear. It is almost universally accepted to be a reflex neurosis originating in the uterus and dependent either upon pregnancy alone or upon co-existent pathological conditions.

Pregnancy itself, the growing ovum, which acts as an irritant by the simple mechanical distension of the uterine cavity and its peritoneal covering, is in the first place to be mentioned as the most potent etiological factor.

Cases of multiple pregnancy and hydramnion, which present a disproportion between the passive distension and the active growth of the uterus, and which frequently are complicated with hyperemesis, confirm this view. Moreover, the induction of artificial abortion, our last resource in desperate cases, which almost immediately relieves the patient when done in time, is founded upon this theory of passive uterine distension, and strongly supports it.

Spontaneous death of the fœtus, followed by immediate or remote abortion, is another remarkable fact in favor of this view.

A patient of mine, the mother of two children, was suffering from double laceration of the cervix, erosion and endometritis. She refused surgical treatment, and was relieved by repeated irrigations of the uterus with carbolized water, and by the application of tincture of iodine. She soon afterward conceived, and her pregnancy was complicated with the ordinary morning-sickness from the second month to the beginning of the sixth, when the vomiting suddenly ceased. Two weeks thereafter she told me that she did no longer feel the movements of the fœtus, that vomiting had ceased, and that she therefore believed the child was dead. Though I could not detect the fœtal heart-sounds, I gave my opinion with reserve. Three and a half months later I delivered her of a dead fœtus about five months old.

This case affords the most striking evidence of the discontinuance of reflex symptoms after the removal of the inciting cause. We have here pregnancy complicated with pathological conditions of the uterus, as double laceration of the cervix, ectropium and probably a but partially cured endometritis, conditions which existed prior to conception and continued after the death of the fœtus. But in spite of the persistence of these pathological conditions of the uterus, and of the retention of the dead fœtus for almost four months, the vomiting disappeared with the death of the fœtus, that is, with the cessation of the mechanical distension of the uterine cavity.

The influence of primary gravidity is demonstrated by the fact that hyperemesis in its grave forms is essentially an affection of primiparous women, and it is to be referred to the greater resistance of the virginal uterus.

Numerous other causes are given as etiological factors by different observers, among them: pathological conditions of the cervix, chronic metritis and endometritis, displacements of the uterus, inflammations of the pelvic peritoneum and connective tissue, ovarian neurosis, neurotic predisposition, hysteria, and lastly, diseases of the gastro-intestinal canal, especially gastric ulcer, chronic gastritis and constipation.

Morbid changes of the uterus are frequently the cause of reflex neuroses in non-

pregnant women. The dependence of gastric disturbances upon the irritability of the uterine nerve-fibers, due to flexion and version of the uterus, to an eroded and congested cervix, to metritis and endometritis, has, in many instances, evidently been proven. Relief has been obtained by the removal of the exciting cause, by the treatment of the uterine diseases after gastric medication had been tried again and again and had failed entirely.

Bearing in mind the physiological changes of the uterus during the pregnant state, its increased functional activity, the influence exerted by gestation upon the nervous system, and the relation between the neuroses and the disorders of the reproductive organs, so often conclusively proven in non-gravid women, we are compelled to acknowledge the various pathological conditions of the uterus as prominent etiological factors deserving our earnest attention. Cases are on record where the application of caustics to the eroded cervix, scarification of the congested vaginal portion, dilatation of the cervical canal, correction of a flexion, have proven successful in stopping the vomiting, and thus demonstrated the connection between the uterine lesion and the reflex nerve action. In other instances, however, the result of the gynæcological treatment has not been so satisfactory, either transitory or no relief has been obtained, and, as a consequence, the influence of the uterine disorders upon the gastric phenomena, their importance as the causative diseases has been questioned.

Undoubtedly it will be often found difficult to decide whether the symptoms result from physiological or pathological causes; whether they are due to distension of the uterus or to morbid changes in the sexual organs. All methods of treatment, artificial abortion excepted, may fail to relieve the patient, and she finally may get well by absolute rest and complete abstinence to the surprise of her medical attendant.

Such cases are certainly rare, while, on the other hand, there is abundant clinical evidence of the effect of local treatment. Numerous women have been benefited by the treatment of the uterine lesion; the reflex symptoms have been mitigated or cured by the improvement of the causative disease, and the connection between both has thereby been confirmed.

Attention has been drawn to the importance of endometritis as an etiological factor by F. Veit, [1] who reported three cases of uncontrollable vomiting, where he was compelled to interrupt pregnancy, and where he found inflammatory processes in the decidua, serotina and vera. Veit believes that by his researches the dependence of hyperemesis upon endometritis is positively proven. As a rule, the endometritis exists prior to gestation, the symptoms are but insignificant, became palpable, however, with the beginning of pregnancy, which frequently is interrupted by this complication. In many instances the endometritis decidua will be found to be the cause of the uncontrollable vomiting; the connection through sympathetic paths must be the same as between gastric disorders and endometritis in nongravid women. The evidence of an anatomical base, he continues, renders a most careful examination of the uterus imperative, and, if the diagnosis of endometritis, which is very difficult before the removal of the ovum, can be made out, it may be of determining influence as regards the advisability of inducing abortion.

Quite recently E. H. Grandin, [2] discussing this subject in the New York Obstetrical Society, suggested ovarian neurosis, pressure on unusually hyperesthetic ovaries as a cause of hyperemesis. This view, he says, would be suggested by Dr. Coe's case, which showed that the physiological vomiting of pregnancy could be palliated by teaching the patient to assume the genu-pectoral positions before rising, and as often during the day as necessary. He would explain the vomiting of pregnancy, then, by the fact that during the early months the uterus lay low in the pelvis and pressed on the ovaries; at the third month, when the vomiting usually ceased, the uterus rose above the pelvic brim. In cases of pernicious vomiting it was possible the ovaries were either enlarged through disease or had become impacted between the pelvic brim and the lower uterine segment.

Grandin's theory, though it may be applicable to a given case, will probably not be favorably accepted. To-day the view is predominant that reflex-neuroses may originate in the uterus, and not in the ovary. The removal of normal ovaries for the relief of reflex symptoms is at present restricted to exceptional cases. and it is believed that if a satisfactory result is obtained by the operation, this is due to the changes in the condition of the uterus, to the artificial induction

[1] Berliner Clinische Wochenschrift, 1887, p. 643.

[2] American Journal of Obstetrics, 1890, p. 1382.

of the menopause, resulting from oophorectomy. Clinical evidence supports this view.

Grandin's explanation, however, may prove valuable in so far as to induce us to carefully examine the ovaries in cases of hyperemesis. Prolapsed ovaries are by no means a rare affection, but it remains to be demonstrated whether pressure exerted upon them by the enlarged uterus stands in causal relation to gastric disturbances.

Nervous disposition and hysteria, so frequently met with among women of the better classes, add greatly to the discomfort of pregnancy, and, though there are certainly many exceptions, must be considered as prominent predisposing factors of the graver forms of vomiting.

The importance of diseases of the gastro-intestinal canal, especially of gastric ulcers, is emphasized by various authors. According to Horwitz [1] "hyperemesis develops in some cases complicated with more or less pathological changes of the stomach and of the intestines. The greater the disturbance in the alimentary canal the easier the ordinary vomiting takes on the character of the uncontrollable form."

The diagnosis of vomiting of pregnancy is by no means as easy as one might think at first sight. While the dependence of this disorder upon the pregnant state may often be determined without much difficulty, cases —especially of the graver forms—may present themselves where this will be found impossible, and where the diagnosis, therefore, must remain doubtful. Faggard[2] directs our attention to the fact "that so few cases of pernicious vomiting are recorded in German medical literature that the existence of this affection is even questioned." Carl Braun, in a fabulous experience of over one hundred and fifty thousand obstetrical cases, has never observed a single fatal termination. On the other hand, Robert Barnes has himselves seen nine fatal cases. McClintock collected close on fifty cases, and O. W. Doe forty-eight cases with eighteen deaths occurring within the last fifteen years, and registered in American and English journals. Gueniot records one hundred and eighteen cases with forty-six deaths.

It is not at all improbable, Faggard continues, that the difference of opinion as to the frequency of this disorder between the Germans on the one hand, and the American, French and English observers on the other, depends, in a large measure, upon the difference in diagnostic criteria insisted upon by the respective schools. In the majority of the fatal cases of alleged hyperemesis due to pregnancy reported by American, French and English observers, there is a notable absence of reliable records of *post-mortem* examinations. In the few cases collected by the Germans, on the other hand, the diagnosis during life has almost invariably been confirmed or negatived by exact investigation of the dead body. Horocks pertinently remarks: "Where there has been no *post-mortem* examination in a fatal case of vomiting, I do not think one is entitled to say that pregnancy caused the fatal vomiting. It may have been the cause, and the only cause, or it may have been an aggravation of some other cause, or may have had nothing to do with it. Scepticism as to the alleged frequency of this disorder in the present state of our knowledge is accordingly eminently in order."

According to Gueniot [1] three distinct factors are to be taken into consideration in making the diagnosis of vomiting of pregnancy: 1st. The diagnosis of pregnancy; 2d. The diagnosis of the adjuvant or determining cause of the vomiting: 3d. The differential diagnosis between obstinate vomiting due to pregnancy and that due to other causes independent of gestation.

It is both interesting and instructive to learn that errors in diagnosis have been made even by eminent clinicians. Thus Faggard[2] tells us that Trousseau once diagnosticated uncontrollable vomiting, and induced abortion in a case in which the autopsy revealed cancer of the stomach. Beau erred in diagnosis in a case in which the *post-mortem* examination showed tubercular meningitis as the probable cause of the vomiting, and Cazeaux narrates the history of a fatal case of alleged hyperemesis of pregnancy where the autopsy disclosed tubercular peritonitis and the abscence of pregnancy.

But a mistake in diagnosis is possible even in the other direction, that is, pregnancy may be denied by the patient or not be expected by the physician, and thus be overlooked as shown in a case recently reported by A. H. Buckmaster.[3] The patient, a governess in a respectable family, was supposed to be suffering from vomiting due to ulcer of the stomach, and was under treatment two months when she died. In making the autopsy a five-months' fœtus was found, but no

ulcer whatever, nothing to account for death except the uncontrollable vomiting of pregnancy.

These cases need no comment. I have cited them to demonstrate both the difficulty and the importance of an accurate diagnosis.

It is generally stated that the prognosis of hyperemesis is bad, but this, apparently, is by no means correct. As Faggard justly remarks, "it is doubtful whether an authentic fatal case of this kind is recorded. Such cases have never been seen by observers of the largest experience."

Even the graver forms of this disease yield, as a rule, to rational treatment, unless they are complicated by serious pathological conditions which of themselves render recovery impossible. Pregnancy may aggravate such cases, and perhaps hasten death, but it must be admitted that there exists no causative relation between gestation and the lethal issue.

A great variety of remedies—still increasing in number every year—have been recommended by different writers. These remedies have proven satisfactory in some cases, but failed entirely in others. This uncertainty of the various methods of treatment, the often but little annoyance caused by the milder forms of vomiting, and the experience that in many instances spontaneous cures occur, have led to the view that interference is not required unless the case presents a more serious aspect. Such advice given in text-books, is at first sight, surprising. Even in mild cases of gastric trouble a careful examination is indicated, and should be insisted upon by the medical attendant to determine the cause of the disorder, its dependence upon physiological or pathological conditions. Are the generative organs found to be normal? Are there no indications of diseases of other vital organs, especially of the stomach? Is the effect of the vomiting upon the general health but insignificant? It may then be decided whether it be a wise plan to irritate the stomach by various drugs, which, as known from experience, are of so limited value in this reflex affection, or to desist from treatment. It is in this sense, I take it, that such advice has been given, and it is under these circumstances that it deserves recommendation. Nevertheless, such statements in text-books are misleading, fortunately, but to the superficial reader.

While mild cases of vomiting do well without treatment, diet and regulation of the bowels, are usually sufficient to render the gastric disturbances tolerable, but the persistent vomiting demands our earnest attention.

Hyperemesis, a reflex neurosis, is due either to physiological changes in the uterus, distension by the growing ovum, or to pathological conditions complicating pregnancy. If we exclude co-existent diseases of the stomach, which will be considered later on, it must seem plausible that the treatment should be directed against the causes and not against the symptoms of the gastric disorder; that is, against the uterus, and not against the stomach. The stomach is not the diseased organ. Nausea and vomiting of pregnancy are only the symptoms of some functional disturbance of the nervous system, originating in the uterus, like the nausea and vomiting of sea-sickness, an analogous disease, dependent upon the motion of the ship. For this reason gastric medication must fail to favorably influence hyperemesis; for this reason none of the innumerable remedies recommended are found to be reliable—some of them are worse than useless.

There are three classes of cases, however, which sometimes may be relieved by the administration of drugs, viz.: 1st. Women who, prior to gestation, have been afflicted with disease of the stomach, as chronic gastritis and gastric ulcer; 2d. Women of an unusual irritability; and 3d. Hysterical women.

In cases of the first category sub-nitrate of bismuth, bicarbonate of sodium, Carlsbad water, oxalate of cerium, the tincture of nux vomica, etc., may be tried and may sometimes be found of decided value, while the nervines and sedatives may give relief to nervous and hysterical women. Opium and its preparations, the bromides and chloral, ether administered by the mouth, by the rectum, or hypodermically, as the circumstances require, are the medicinal agents which have the best reputation, and which, in these cases, sometimes successfully depress the reflex irritability, and thus alleviate the symptoms. Blisters, the application of chloroform, ether, and of the faradic current to the epigastrium, of the ice-bag to the dorso-lumbar region have been tried and have afforded relief in some instances.

The resort to local treatment is indicated in all those cases in which a morbid condition of the uterus has been made out. Retroflexion and retroversion are to be corrected, and, if necessary, the uterus is to be retained in position by a suitable pessary. A congested vaginal portion may be relieved by scarifications, while the application of carbolic acid, or of a 10 per cent. solution of nitrate of silver to the eroded cervix will

often prove successful in mitigating the distressing symptoms. Faggard[1] states that in Vienna a 10 per cent. solution of nitrate of silver is employed in all cases of severe vomiting, irrespective of the condition of the vaginal portion. "The weight of testimony in favor of this simple procedure, collected from innumerable sources, is so great as to make its employment absolutely obligatory before resorting to more radical methods."

Dilatation of the cervix—Copeman's method—has proven successful according to some writers, while others report negative results. In the only case of severe vomiting which I have observed it had a most remarkable effect. The nausea disappeared instantly, but only for a few hours. The method was again applied, but no result was obtained the second time.

Horwitz [2] recommends that in the severer cases of vomiting the patient should be placed at rest in bed in the horizontal position, that the room be darkened, and that, if the stomach rejects everything, rectal alimentation should he resorted to. Crushed ice to quench the thirst is allowable. I can fully endorse this plan.

When these various methods have failed, when the vomiting actually is uncontrollable and seriously endangers the patient's life, the induction of abortion or premature labor is indicated, and will, if done in time, to a certainty, save the woman.

Society Reports.

ALLEGHENY COUNTY MEDICAL SOCIETY.

Scientific Meeting, June 16th, 1891.

T. D. DAVIS, M. D., PRESIDENT, IN THE CHAIR.

Dr. Blume read a paper on the Vomiting of Pregnancy. See page ——.

Dr. LeMoyne:—I agree with the doctor that in a great many cases vomiting is largely due to abnormal conditions of the parts. I had the same experience with obstinate vomiting in this condition, and found it often was relieved by the correction of some erosion or displacement, although I do not believe that that always caused the condition. The doctor has very wisely laid a great deal of stress upon the matter of careful examination of the parts where these conditions exist, with the view of ascertaining and removing any such abnormal conditions.

Dr. Lange:—An excellent paper the doctor has given us; it deserves our thanks. It is very comprehensive and thorough, and there is nothing in it to which any one can raise any objection, except perhaps this: the rectification of displacement of the uterus during pregnancy by the use of pessaries. That, in my experience, is impossible. In an impregnated uterus, and perhaps in a uterus which is not impregnated, I think that it is beginning to be thoroughly understood that the pessary is a means of absolutely no value, sometimes of great discomfort, and occasionally of some danger. The only pessary which may perhaps be sometimes of service is the ordinary balloon pessary, a rubber globe which is ballooned up by inflation with air or water. This—in my experience—prevents the descent of the uterus in some cases. The stem pessary of Dr. Kinloch may also be an exception to the rule, that pessaries are useless for uterine displacement; this can be used of course only in the unimpregnated uterus, and may deserve consideration in flexions. Among the remedies which the doctor has mentioned are the most valuable, but I failed to hear calomel. Calomel has been, in my experience, a most valuable remedy. In proof of this, I had a lady under my care who had twice suffered abortion at four months, at the hands of most eminent gentlemen in the profession, because of pernicious vomiting, and their conclusion was that she would die. At her third pregnancy she and her husband again concluded that she would die, and she certainly looked like it. Her adipose tissue had disappeared, her muscular system had atrophied, her belly was distended and tender, she was blanched, her pulse was small and rapid, she had an elevated temperature, and her tongue was red and dry. I gave her calomel, one-eighth grain every three hours. In 48 hours she was able to retain *some* food, in two weeks she left her bed, still sick, still vomiting, but able, despite her vomiting, to take a sufficient amount of food to maintain life and improve her condition. This is one instance where calomel exerted a very marked good effect, and this was not due to any organic disease of the stomach; sufficient proof of this is the fact that, before her pregnancy she was always well, and the same was true before her previous pregnancies. She is the wife of a druggist in this city. I give calomel frequently in the vomiting of pregnancy,

[1] l. c.

[2] l. c.

but in the case related it strikingly exhibited its power. The doctor mentioned a remedy with which I have no experience in the vomiting of pregnancy, but of which I have heard much good. I have always understood that the introduction of that method belonged to a Pittsburgher, namely, Dr. M. O. Jones, of Wylie avenue, who informed Dr. Marion Sims of it; the latter teaching it in Paris in 1870. I have always understood that dilatation of the cervix and the separation of the membranes a little way up, which is said to be a very excellent remedy for the ordinary sickness of pregnancy, is the method of Dr. Jones.

Dr. Dagette:—The doctor speaks of increased temperature being one of the symptoms of pernicious vomiting. Is that one of the signs which arise before death?

Dr. Blume:—In my case, after about two weeks had passed fever commenced, and after another week had passed, the woman still in bed, her fever went up to 103° and remained at that height for several weeks, and this case recovered without any medicine whatever, having nothing but absolute rest. She was in bed about six weeks.

Dr. Batten;—I have had two cases of severe vomiting of pregnancy. One was in the person of an unmarried woman. At first I could not imagine (she was supposed to be a virgin) what the trouble could be. She was emaciated and her eyes were sunken; after two or three days my suspicion was aroused. There was no fever. The case went on for two weeks under my treatment with all the remedies that I knew of, excepting local applications, and from the fact that the young woman made the request that I keep her mother in darkness as to the cause of the trouble, I was prevented from making any local applications. But after exhausting everything I returned to blackberry brandy and stopped all medicine; after giving her the second dose, the vomiting ceased and she recovered after taking the remedy for some three weeks. Another case I had in 1882. A woman had seven children and never had any vomiting whatever; in this case the vomiting appeared at the end of the first month and continued right along to the end of the fifth month, and all remedies seemed to have no control whatever of the trouble. However, at the end of the fifth month, after I had given up the treatment, she was not so prostrated as the other case. It was a twin pregnancy, and when that woman was delivered one child was fully developed and another was dead, having died evidently at about the fifth month, about the time the sickness left her. The dead fœtus was in the neighborhood of five or six inches long. The woman ran on to full time.

Dr. Connell:—One point the doctor alluded to, the use of nitrate of silver. My attention was first called to the use of this remedy by Dr. Jones, whose name has been mentioned, and I think to him belongs the credit of the introduction of nitrate of silver treatment. In the *Journal of the American Medical Association*, of two years ago, there was a paper written by a gynæcologist or obstetrician of Washington, whose name I cannot now recall, and in reply to that, Dr. Jones gave his experience in the use of nitrate of silver, and alluded to having spoken to Dr. Sims about it. Dr. Jones used that many years ago, and it is only a few years since the attention of the profession was called to it. I have used it and had better results with the application of the nitrate of silver than with any other remedy.

Dr. Huselton:—I want to say a word in defense of the pessary. I think that we have displacements of the uterus in the early stages of pregnancy. I also believe it is possible to rectify them and maintain them in proper position by the use of Thomas' retroversion pessary. I have certainly replaced retroverted uteri and maintained them in position with this pessary. With regard to treatment, as has been properly stated, I do not know of any one remedy that will relieve all cases. I remember one very aggravated case I had a number of years ago, in which I tried everything that I could think of, which I afterwards succeeded in relieving entirely with a large dose of chloride of potassium.

Dr. Green:—I have no criticism to offer on the paper. I wish to relate a case of vomiting during pregnancy which came under my observation on the sixth of this month. The lady was three months pregnant. She had been treated by two or three physicians previous to her application to me. I do not know what remedies she had taken, but no relief had been afforded by any of them. I found her very much prostrated, and for five or six weeks she had had difficulty in retaining food sufficient to afford nourishment; she had not rejected all the food and was still able to go about. An examination of the uterus discovered it to be displaced, retroflexed and apparently bound down with adhesions, and abortion was about to take place. There was evident hæmorrhage, which had begun some time the previous night. She miscarried on the second day after I saw her. Again, I wish

to say a word in regard to the use of the pessary. Whilst I have no doubt that the pessary may in certain cases do some damage, I have seen what I supposed was very great benefit, in the use of the soft pessary; especially in cases coming under the class where displacement can be assigned as the cause, I have seen permanent relief. I wish to say a word about the damage sometimes done by pessaries. About six weeks ago I delivered a lady at term. On making examination, I found a common ring pessary, hard rubber. I said: "How long have you worn this?" She replied, "About five years." Six years previously she had given birth to a child and immediately after that this pessary had been placed in the vagina and remained there ever since. I removed the pessary, and saw that it had done no harm. This, I presume, does not very often occur. It shows that the pessary does not always do very great damage.

Dr. Werder:—I have no personal experience in this matter. I have had a large number of pregnant women under my observation, but have never seen a case of serious vomiting of pregnancy. There is no doubt that vomiting of pregnancy is a reflex neuroses—of course that is not saying very much—but I think in a large number of cases it is a form of hysteria. A number of cases have been reported which were treated as hysteria and got well under that treatment; before that, other methods of treatment were employed without any benefit whatever. I think there is no doubt that a large number of cases are hysterical in their character. In regard to pessaries, I have no doubt that pessaries are used very much, and very many women would be far better without them, but there are exceptions to that. I think a good many women would would not feel comfortable without the pessary. If the uterus is properly replaced and in normal position and a pessary is introduced, where there is no inflammatory condition of the pelvis, in many cases it does a great deal of good. Many of these women are very comfortable wearing a pessary for months, and women come to me with pessaries where there is no flexion at all, where there is no displacement of the womb, and sometimes there is a displacement, but it has not been reduced at all, the uterus is retroflexed just the same as it was before the pessary was introduced. In pregnancy I have had probably two or three cases of this class, and am certain that these women suffered before the uterus was put in position and before the pessary was introduced, and the benefit they derived from the pessary was also very great.

Dr. Davis:—Dr. Blume certainly covers the ground in every particular very thoroughly, and there is one point that he dwelt on and that is, as he said very aptly, you would think that the diagnosis of pregnancy was a very easy thing, and yet I believe this is an important point of the question for discussion to-night. I believe that on that hangs the treatment, and that is the reason why such various treatments are recommended, and why in some cases one treatment acts very favorably and another treatment is of no benefit. I think it stands to reason that if pregnancy is the cause of this vomiting, calomel would have very little effect. I think it stands to reason that if there is no (or very little) trouble of the uterus, but if there is a disease of the stomach, calomel would be very beneficial. And therefore, while in one case I would expect benefit from it, in the other, it would be *nil*. On one occasion I was called to see two ladies, neighbors, both suffering with morning sickness of no aggravated form, but enough to give them great discomfort. To the one I prescribed to the best of my judgment what was wanted, bromide of potash. To the other I prescribed hypophosphites in an acid solution. I remember distinctly, they were given in quite large bottles; they each used about half of the bottles; which were given within a day or two of the same time, and were none the better, but rather grew worse. Talking, as neighbors will do, over the back fence, they compared notes and traded bottles, and in a very short time both were completely relieved. The explanation is simply this, that the acid and the hypophosphites in the state of the one stomach was just what was needed, while the nervine and the alkali was just what the other needed. I believe that as far as we possibly can we ought to ascertain what is producing this particular sickness in this particular woman, and not take it for granted that all morning sicknesses are from identically the same cause. In my experience I have seen a great many severe cases. Pregnancy acts differently in different persons, and the thing that would remedy one case would be useless in another. I have seen a good many that I considered very severe cases, but it has been my lot to see one that was of unusual severity, at least the result shows it to have been so.

A lady, whose medical history I know comparatively little, came under my observation for four visits. She was several months

gone in pregnancy and was suffering with profound morning sickness. A particular characteristic of it, as I noticed in these four visits, which extended over about ten days, was ptyalism. In fact in my presence she was so overcome that she had to vomit. As I was seeing the case in connection with another physician, a friend and relative, who had been there about an hour before my last visit, I did not push the investigation at that time as I had no particular alarm. That was on Thursday evening. It had been the case for the husband to drop in to tell me how she was feeling, and to telephone if she was feeling unusually bad. Thursday evening I saw her last. Sabbath morning the physician dropped in and told me he had called and found her in a very critical condition. It seems that on Friday morning a lady physician had been called in, and on Friday and Saturday had seen her in this condition of increasing irritation of the stomach, and vomiting of some cloudy fluid, and on Sabbath morning when her friend, the physician, saw her, she was in a critical condition, and in spite of dilatation and everything else that could be accomplished on Sabbath night, she died on Monday. I felt impressed at the time and more impressed upon hearing Dr. Blume's paper tonight, that a *post mortem* examination should have been held on the case.

Dr. Kœnig:—It seems to me that in looking for a specific cause of vomiting in pregnancy, we overlook the fact that the nervous system is very powerfully affected by the pregnancy itself. Vomiting in pregnancy is so common that it cannot be due to a gastric lesion; it must depend on an irritation of a nerve ganglion that transmits it to the brain. It has been said that it is impossible to explain why the peculiar motion of a ship should produce vomiting; I have never heard it explained; I do not suppose we can explain it; nor can we explain satisfactorily how the vomiting of pregnancy is produced. It would appear to me that the action of all remedies that are of any value can be accounted for in two ways, one a counter-irritation, which would explain the action of pessaries; explain the action of nitrate of silver when applied to the os; and would explain the action of dilatation. By these an irritation is produced which diverts the attention of nature from the disturbing causes which produce vomiting. The artificial irritation at the os distracts the attention of nature from the other point of irritation, and the vomiting ceases. The other action to which I refer is an anæsthetic action applied to the terminal nerve filaments of the stomach. I have recently seen a remedy possessing this action recommended, which Dr. Blume did not refer to in his paper, namely, menthol, in two grain doses. Menthol is a powerful anæsthetic, and by deadening the sensibility of the nerves of the stomach, I can very readily conceive how the vomiting might be arrested. We all know the tendency of disease is toward recovery, and if vomiting in pregnancy is a disease, it is especially true in this case. That fact accounts for the numerous remedies that are said to be corrective. That fact might account for the re-results that followed the exchange of remedies in the case alluded to by the President. A large majority of cases recover without medication.

Dr. Duff:—I would make the distinction in discussing this subject between simple vomiting during the ordinary morning sickness of pregnancy, the more persistent and aggravated vomiting, and the pernicious vomiting. There is a conservatism of nature in the first class; indeed, some observers declare this to be so, inasmuch as women thus affected go through their pregnancy as a rule better than do those who are not. The pernicious vomiting due entirely to pregnancy without complications is, I think, a rarity. The failure up to this time, of observers to agree upon any common cause of vomiting during pregnancy is *prima facie* evidence of varying causes. Our treatment, therefore, should depend upon a rational consideration of each case presented to us. In the cases of Dr. Davis, I do not think that when the exchange of medicine was made the patients were about to get well. I think the exchange was a happy one, inasmuch as the then treatment was in accordance with the acid or alkaline condition of the secretions. I did not notice that the doctor said anything about electric treatment. I think it is sometimes efficacious. Another mode of treatment is the application of cocaine to the cervix uteri. Injecting it into the tissues of the cervix, I think gives the best results, although painting with a 15 per cent. solution may answer as well.

Dr. Blume: It has been said, that pessaries should not be employed to retain a gravid uterus which has been retroflected. Vomiting, as a rule, occurs during the first few months of pregnancy; the replaced uterus will at so early a period of gestation often need a support or become again retroflected. We have two means to retain the

uterus in its normal position: 1st. Tampons; 2d. Pessaries. Tampons must frequently be changed, are therefore inconvenient and even injurious, as they may incite contractions and thus produce abortion. A suitable pessary does no harm under these circumstances, as I have seen in many instances. Stem-pessaries cannot be considered here. In my opinion they should never be used. They are certainly contra-indicated during pregnancy.

Calomel has not been mentioned by me because it failed entirely to influence the gastric disturbances in my cases. It acts as a simple purgative, and is indicated or may be tried in cases complicated with costiveness.

Gastric medication is applicable only in the milder forms of vomiting. Cases of pernicious vomiting, where everything is rejected by the stomach, cannot be relieved by drugs, be they given by the mouth, by the rectum, or hypodermically. It may sometimes be possible to stop the vomiting for a few hours, but, as a consequence, the nausea becomes so intense that the patient feels relieved as soon as the vomiting commences again.

One gentleman said that dilatation of the cervical canal has been practiced many years ago. This method, first recommended by Copeman, justly bears his name: Copeman's method. Dilatation of the cervix, if carefully effected, does not interrupt pregnancy. But if the internal os is dilated, or, as one gentleman recommended to-night, if the membranes are detached around the internal os, abortion will probably be the consequence.

The view, expressed by one gentleman, that patients with the ordinary vomiting do better at term than those without this disorder, is at least surprising and by no means supported by experience.

In conclusion I wish to *touch* a point which I have not discussed in my paper, viz.: when has the vomiting become uncontrollable, and when is the induction of abortion indicated? This question is a very important one, for if we wait too long the woman will in all probability lose her life. Uncontrollable vomiting is apparently very rare in our vicinity. The case reported by Dr. Davis is the only one I heard of in this city, and I regret that no autopsy has been made. In New York where this subject has been discussed in the Obstetrical Society last fall, pernicious vomiting must be a rather frequent complication, as almost every speaker reported cases where artificial abortion had to be induced to save the patient. Several women died, the evacuation of the uterine contents having been too long delayed. All the speakers agreed that abortion should be induced before the condition of the patient had become critical.

I believe that no precise rules can be given as to when to empty the uterus, and that every case must be treated according to its peculiarities. When the various methods of treatment have been tried in vain, when the patient becomes more and more emaciated, it seems hazardous to wait for the most extreme degree of exhaustion. A consultation should be held and the induction of abortion, the last chance of saving the woman's life, should not be postponed too long.

Dr. LeMoyne: In December, 1890, I was requested to see a woman in consultation, who was supposed to be six and a half months pregnant. She had been delivered of two children at full term previously, and had one miscarriage at about six months. For about two weeks she had noticed some swelling of the lower extremities, and a specimen of her urine, which was procured the evening previous to my attendance, was found to be so largely composed of albumen as almost to solidify by boiling. She had taken her evening meal with her family, between six and seven o'clock, but while at the table experienced considerable pain in the abdominal region, and was compelled to retire before finishing. She was assisted to bed, and medical attention procured. Between that time and six o'clock the following morning she had three very decided convulsions. At six o'clock, A. M., her expression was rather dull, but she responded intelligently to questions, and recognized persons who addressed her. The mouth of the uterus was sufficiently patulous to admit the point of a finger, which readily detected the body of the fœtus. No instrumental apparatus being at hand for the dilatation of the neck of the uterus, suitable appliances were immediately sent for. But the patient's condition being such as to promise an early return of the convulsions, admitted of no delay, and dilatation was practiced with great perseverance and determination by means of the fingers. The success of this method was such that when the Bames dilators and parallel steel blades arrived, the divulsion was beyond their capacity, but not sufficient to admit the hand. At 9.00 A. M., no relief being experienced and every moment seeming to endanger the patient's life, the long obstetrical forceps were resorted to with the intention of either grasping the fœtus in their blades and forcing it away, or

effectually dilating the mouth of the uterus by delivering the forceps in the locked position. The mentioned plan failed, as no engagement could be procured; but with little difficulty the blades were successfully introduced, locked, and gradually delivered, dilating the uterus sufficiently to enable the hand to enter, seize the thighs of a breech-presenting fœtus, and accomplish its speedy delivery. Two modified convulsions occurred after the delivery, and five severe ones previous to it. The normal function of the kidneys was soon re-established, and a very satisfactory recovery soon followed.

I offer the history of this case believing it to illustrate a very valuable and nearly always practicable method of dilating the uterus, and thinking that it may be new to others as it has been to me.

Dr. Duff: The simple introduction of the forceps through the os, locking them without grasping any portion of the child, and withdrawing them for the purpose of dilatation, it appears to me would be impossible except where the head was still above the superior strait, where there was the same condition in a breech, or where there was an oblique presentation. I have frequently introduced the forceps where the os was only dilated sufficiently to admit of their introduction with the double purpose of dilating and of traction. I think Dr. LeMoyne's method justifiable.

Dr. Blume: If delivery by the head should be impossible, I think it is safest to turn by the hand and extract; a woman could be delivered in that way. I do not know in this case whether the child was living or not. I think we have other measures which should be tried first; for instance, anæsthesia.

Dr. LeMoyne: The dilating of the os, I stated in my paper, was done by physical means. I introduced my fingers, first one finger and then another finger beside it, and finally two fingers and the thumb, until I reached a degree of dilatation that would admit the blades of the forceps consecutively. I also stated that, having no suitable instrument for the purpose when the case was thrust upon my treatment, I had to resort to natural means, and by the time the instruments arrived by which I expected to accomplish dilatation, I had already dilated to a sufficient extent with my fingers to introduce the blades of the forceps, and my diagnosis of the position being still uncertain, I introduced the forceps with the intention of seizing any part which might present. It strikes me as very fortunate thought, and resulted certainly very favorably.

Selected Formulæ.

FORMULÆ FOR SOZOIODOL.

Sozoiodol in the following combination will be found a valuable dressing for burns and bruises:

℞
Sozoiodol of potassium..... 3 grammes.
Lanolin.....30 grammes.
M.

The following formula may also be used advantageously in similar instances:

℞
Sozoiodol of potassium..... 5 grammes.
Talcum.....20 grammes.
M.

In various eczematous diseases of the skin sozoiodol of soda will be found of value.

℞
Sozoiodol of soda..... 2 grammes.
Talcum.....20 grammes.
M.

In similar cases the following is equally as useful:

℞
Sozoiodol of mercury..... 0.5 gramme.
Lanolin.....25.0 grammes.

Finally the drug has yielded excellent results in the treatment of blennorrhagia when given as follows:

℞
Sozoiodol of zinc..... 1.5 grammes.
Distilled water.....100.0 grammes.
Tincture of opium ..... xx gtt.
M.

—*Journal de Méd. de Paris.*

FORMULÆ FOR NAPHTHOL.

The following formulæ for naphthol will be found valuable in the treatment of acne:

℞
Camphorated naphthol, Resorcin, Salicylic acid } aa..... 5 grammes.
Starch, Vaselin, Precipitated sulphur } aa.....25 grammes.
M. et fiat pasta.

The above is recommended by Dr. Besnier.

Another naphthol paste, recommended by Lassar, is the following:

℞
Naphthol.....10 grammes.
Washed sulphur.....50 grammes.
Green soap, Vaselin } aa.....25 grammes.
M. et fiat pasta. Sig. To be left in place after application from one-half hour to one hour.

In cases of inflammatory acne, Dr. Brocq uses the following with success:

℞
Naphthol B.....1 gramme.
Washed sulphur.....2 grammes.
Pulv. oxide of zinc.....2 grammes.
Lanolin.....5 grammes.
Oil of sweet almonds.....7 grammes.
Extract of violet, q. s.

For chronic eczema, Brocq recommends this salve:

℞
Naphthol B.....1-2 grammes.
Vaselin..... 50 grammes.
M.

—*Journal de Méd. de Paris.*

ACUTE AND CHRONIC CATARRH.

℞
Terebene.....ʒiij.
Ol. cinnamoni.....ʒss.
Gum acaciæ pulv.....ʒv.
Sacch. alb.....ʒiv.
Tinct. card. co.....ʒiij.
Syrup simpl.....ʒx.
M. Sig. A teaspoonful three or four times a day.

—*The Prescription.*

SCABIES.

Dr. Cantrell gave the following prescription in a case of scabies:

℞
Beta naphthol.
Sulphur, aa.....ʒij.
Adipis.....ʒiv. M.
Sig. Apply to affected part.

Also frequent bathing; and the clothing is to be scalded.—*Coll. Clin. Rec.*

GOUT AND RHEUMATISM.

There can be no possible doubt that, despite the different opinions in regard to the cause of gout and rheumatism, alkalies exercise a very good action, and tend to relieve the system of that hyper-acidity which seems to be always present. In this administration of alkalies, some care is to be exercised in order to avoid those disturbances of the digestive system which may come on as a result of their continued administration. Among the best of the alkalies is lithium and its salts. Some, however, contend that its combination with other alkalies makes its action more sure and effective. A combination devised by an eminent practitioner is as follows:

℞
Lithium benzoate.....12.823 grains.
Lithium bicarbonate.....13.784 grains.
Potassium bicarbonate.....10.000 grains.
Sodium chloride.....10.000 grains.
Carbonated water.....16 ounces. M.

This makes a palatable, effervescing mixture which is very grateful to take, as well as effective in action. Of course, it is impossible to prepare this extemporaneously. Dr. Enno Sander has made the above in his usual thorough manner, and has named it Benzoated Lithium Water. Being palatable, it is taken by patients with a certain relish, and the peculiar taste of the alkalies does not manifest itself, being completely covered by the carbonated water.—*Weekly Medical Review.*

BALDNESS.

In falling of the hair, a writer in the *Lancet* recommends the following, a little to be rubbed on every night:

℞
Tinct. jaborandi.....fʒiv.
Lanolin.....fʒiij.
Glycerin..... ʒij.

PRURITUS HIEMALIS.

Corlett recommends the following topical applications in "winter itch":

℞
Resorcin.....ʒj.
Glycerin.....fʒij.
Aquæ, ad..... .....fʒiv.
M. Sig. Apply.

℞
Menthol..... ....ʒiiiss.
Glycerin.....fʒij.
Aquæ, ad.....fʒiv.
M. Sig. Apply.

℞
Ichthyol. ammon. sulph.....ʒi-ij.
Glycerin.....fʒij.
Alcohol.
Aquæ, aa q. s. ad.....fʒv.
M. Sig. Apply.

—*Boston Med. Journal.*

AMENORRHŒA.

A writer in *Revue Med.-chir. des Mal. des Femmes* prescribes:

℞
Bichloride of mercury.....3 grains.
Arsenite of sodium.....3 grains.
Sulphate of strychnine.....1½ grains.
Carbonate of potass. } .....each 45 grains.
Sulphate of iron }
Make into 60 pills and give one pill after each meal.

—*Ex.*

SPASMODIC COUGH.

Dr. Brubaker recommends the following prescription for spasmodic cough:

℞
Acid. hydrocyan. dilut.....fʒj.
Tinct. sanguinariæ.....fʒiv.
Syrup, senegæ.....fʒss.
Syrup, tolu.....fʒij.
Aquæ lauro cerasi, q. s. ad.....fʒviij.
M. Sig. fʒj t. d.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

EDWARD T. REICHERT, M. D.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF PENNA.,
EDITOR AND MANAGER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

THE MEDICAL AND SURGICAL REPORTER.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent 3 months on trial for $1.

At the termination of the period of subscription, we will promptly discontinue sending THE REPORTER unless directed to the contrary by the subscriber.

Remittances should be made by draft, check, postal note, or money order payable to Edward T. Reichert.

THE POCKET RECORD AND VISITING LIST.

Two sizes. Prices to subscribers of THE REPORTER: For 30 patients a week (with or without dates), $1.00. For 60 patients a week (without dates), . . $1.25. Prices to non-subscribers, $1.25 and $1.50 respectively.

THE MODEL LEDGER.

Physicians who keep their own books will find this of great value. Sample pages sent on application. Price, $5.00.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If THE REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS.

Write in ink.

Write on one side of paper only.

Write on foolscap or legalcap paper.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be pleased to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

LEADING ARTICLE.

INTUBATION OF THE LARYNX.

The operation of Intubation of the Larynx, has of late awakened such great interest among surgeons and pædiatrists both here and abroad, and has found such extended adoption, that a brief review of the advancements made, the successes achieved, as well as the failures, cannot fail to be of great interest to our readers; and more than this, because the operation is eminently an American one.

Although a comparatively new procedure, the number of intubations that have been performed are truly startling, Dr. Lovett, of Boston, having been able to collect the histories of 21,853 cases. Unlike many recently introduced surgical and therapeutic procedures, which, while heralded with flourish of trumpets and the sounding bravos of the all too optimistic members of our profession, have been finally relegated to a position of acknowledged worthlessness, made only more bitter for their advocates by their ephemeral glory—unlike these, intubation of the larynx came upon us modestly, promising but little, starting, as it were, at the bottom rung of the ladder, only, however, to mount with ever increasing swiftness until now, although still in its youth, its success has been so firmly established that the foremost of the profession, in America, France, Germany, England, Italy and elsewhere, are practicing the operation, and already the name of O'Dwyer has been made memorable.

The REPORTER has not been silent on the subject. In our issue for May 9, 1891, we published the report of Dr. J. Mount Bleyer, as it appeared in the *Archives of Pœdiatrics*. Dr. Bleyer gives the report of 512 cases of intubation of the larynx for croup and diphtheria, operated upon between 1886 and 1890, out of which 37 per cent, recovered. Among the causes of death in the 322 fatal cases, extension of the false membrane occurred in 67 cases; bronchitis in 45 cases; pneumonia in 41 cases; broncho-pneumonia in 40 cases;

sepsis in 39 cases; and asphyxia due to closing of the tube by false membrane in 2 cases. In the article referred to, the author strongly emphasized the necessity for making a forced or normal laryngoscopic examination before operating, as the differentiation and diagnostication of other laryngeal diseases may be made out, and the extent of the diphtherial or croupous lesion seen. The tube, says Bleyer, should be extracted daily for the purpose of removing any accumulation of loose membrane, tenacious mucus or pus. "When the tube has been extracted irrigate the posterior nares, pharynx, larynx and entire surface with a mild solution of bicarbonate of sodium." Much of the success depends upon the judgment of the operator in selecting a suitable tube. When loose membrane exists, Bleyer recommends a tube of thinner metal and larger calibre, which should be left *in situ* six hours or more. "The tube once in place," continues Bleyer, "the most vital portion of the treatment must be next carried out, namely, irrigation of the affected parts. A number 8 soft rubber catheter attached to a fountain-bag syringe, is passed into the nostrils alternately,and a solution of peroxide of hydrogen (5 ounces of a 15 volume solution, chemically pure, in 12 ounces of water) is passed through; after this has been done, the next step is to wash out the mouth, pharynx and larynx. If necessary a gag should be used." Dr. Bleyer then gives a brief summary of the results of the operation, finding that German authors have obtained 31 per cent. recoveries in 5,795 cases: German Hospitals had then recorded 30 per cent. recoveries in 3,063 cases. French surgeons had tabulated 9,242 cases with 24 per cent. recoveries. In the Boston City Hospital, according to Dr. Lovett, of Boston, between 1884 and 1887, 327 operations yielded 29 per cent of recoveries. Out of the 21,853 cases collected from all sources by Dr. Lovett, and previously mentioned in this article, 26½ per cent. of recoveries were obtained.

In the Reporter for June 20, 1891, we referred editorially to this subject, under the heading of "Tracheotomy vs. Intubation." At that time we took a most conservative view of the matter, and our conclusions then drawn must probably be modified by the weight of the extended experiences of well-known clinicians, as well as the unmistakable importance of the most recent and unbiased statistics.

Again, in the Reporter for August 1, 1891, we published an abstract of an article by Dr. Hal Foster, which appeared in the *Kansas Medical Journal*, which is nought but an unqualified enconium of the operation, based upon personal experience and extended research.

Finally, in the Reporter for August 8, 1891, there appeared a communication on this subject by Professor F. Massei, M. D., of Naples, Italy. Dr. Massei's interesting and valuable article is too fresh in our readers' memories to necessitate of our recalling even its most salient points. The author's frankness in acknowledging himself firmly opposed to the introduction of intubation into Italy on purely theoretical grounds, together with his present warm support of the procedure, the result of personal and practical experience—these admissions alone, coming from the source they do, carry a weight with them that will surely strengthen the already firm foothold that the operation has won for itself. Professor Massei speaks, in his article, most highly of Dr. Egidi, of Rome, whom he also confesses to have strenuously opposed at the outset. Dr. F. Egidi, without doubt, deserves the title of "pioneer" of the operation of intubation in Italy. In an exhaustive article on the subject, which appeared in the *Giorni Internaz, dell Scienz. Med.*, March 15, 1891, he states that he performed his first intubation in April, 1889, and that this was the first operation of the kind performed in Italy. Dr. Egidi cites the histories of 30 cases, of which 27 were in children and 3 in adults. Of the children, 21 were cases of primary, or simple croup, 2 of croup consecutive to diphtheria of fauces, 3 of croup following measles, and 1 of stenosis following the use of a tracheotomy tube. The youngest child was ten months old, 17 were between one and three years, and 9 between three and five years. Omitting the case of stenosis

after tracheotomy, of the remaining 26 cases, 4 recovered, all of primary croup. Introduction of the tube was generally easily performed although in his first case the tube was only inserted after seven attempts. It happened in two cases that some false membrane was pushed down before the tube, but which was coughed up when the tube was removed. No great difficulty was experienced in feeding the children. Coughing up of the tube soon after introduction occurred in three cases, but as soon as a tube of a larger size was inserted there was no further trouble. The tube in Egidis' cases was worn for periods varying from twenty-two hours to thirteen days. Extraction of the tube was done with the extractor in four cases, but Egidi prefers —as does also Massei—to leave the thread *in situ*, and to remove the tube by it instead of by the extractor, the latter procedure being very difficult. In only one case was an erosion from pressure of the tube found *post mortem*.

Regarding Massei's results, they are more satisfactory even than those of Egidi. Out of 11 intubations he obtained 5 recoveries, or $45\frac{5}{11}$ per cent. More particularly in 9 cases of croup, 6 recoveries, or $66\frac{2}{3}$ per cent.; in two cases of laryngitis stridulus, 1 recovery, or 50 per cent. Furthermore, Massei states that in the five cases that ended fatally intubation was done by the way of an experiment, as the patients were all in a very bad condition, and presented no hope of recovery.

If the results of tracheotomy are compared with those of intubation we cannot fail to observe that there are some important advantages in intubation. It is a well-known fact that erysipelas or traumatic diphtheria not infrequently follows the operation of tracheotomy. Thiersch, out of 697 cases of tracheotomy, observed 74 cases of traumatic erysipelas, 50 of which resulted fatally.

There is undoubtedly more or less difficulty in feeding the subjects after intubation, but the majority of writers state that they have been able to overcome this difficulty without serious trouble. Ice may be given to quench the thirst, and nutritive enemata resorted to should the case indicate it.

The theory has been advanced by Schwalbe, and others, that the tube in pushing down before it false membranes, only adds to the faulty ventilation of the lungs and in this way can very possibly be the cause of pneumonia. This possibility should not be forgotten. A single introduction of the tube occasions violent coughing, which leads to the expulsion of mucus and false membrane. This fact was also observed and made use of by Bleyer, and he found one or two consecutive introductions of value. Indeed, Francis Huber, basing his opinion upon this fact, has established a special treatment in bronchial-croup, which he designates as "Intermittent Intubation." Such, or even a similar action is unobtainable in tracheotomy. The statistics of the two operations, tracheotomy and intubation, as compiled by Ranke, do not show that pneumonia is any more frequent after intubation than after tracheotomy.

The aspect might, perhaps, be a different one in cases where pulmonary disease already existed. Here, it is very possible, that the calibre of the tube would not suffice to allow of the increased respiratory effort demanded by the disease. In event of such complications Escherich is right in considering the procedure contra-indicated.

It is of greatest importance that the operation should be conducted without the use of force, viz., in the insertion of the tube. By neglecting this point, serious injuries to the membranes and parts, inviting septic infections, can be made; and apart from this, the possibility of making a false passage. It is, therefore, of high importance, that the operator should thoroughly understand and have had practice in the technique of the operation, and this experience should not be gained from the living subject but from the cadaver.

The value of experience will be doubly appreciated after a careful study of the results of various operations, when it will be

seen that the rate of mortality steadily decreases with the gain of experience. Thus Dillon Brown obtained 22 recoveries in his first 100 cases, 32 recoveries in his second hundred, and 33 in his third; Waxham obtained 26 recoveries in his first 100 cases, and 33 in his second; O'Dwyer himself reports 17 recoveries in his first 100 cases, 27 in his second, and in 77 cases of his third and latest report of cases there were 62 recoveries; or in all 33 per cent.

Of course, some operators have had discouraging results, and their opinion of the operation has suffered accordingly. Notably among these is Dr. Schwalbe, whose address to the Medical Society of Berlin, was anything but in support of the operation. The statistics of other continental operators, as gleaned by Dr. A. Rosenberg, reported to the Berlin Medical Society, and published in the *Berliner Klein Wochenschrift*, June 22, 1891, are too positive to be misconstrued, and would lead one to believe that repeated failures were due to lack of skill or unprecedently unfavorable complications, rather than the fault of the operation itself.

Thus Ranke's present percentage of recoveries is 32.7 per cent., Ganghofner 48.6 per cent., von Muralt 32.5 per cent., and von Wiederhofer actually 50 per cent.

These unadorned statistics need no comment, and sufficiently prove the triumph of the operation.

The value of any operation can only be proven by the comparison of most extended statistics, and even these are sure to be more or less faulty. It will be of interest to our readers to quote briefly the results of Ranke's researches on this subject, as reported by him to the Pædiatric Section of the meeting of Natural Scientists in Heidelberg, in 1889. He collected, as far as possible, the available histories of all intubations and tracheotomies in Germany, Austria and Switzerland, numbering 413 intubations and 866 tracheotomies. In primary diphtheria, tracheotomy yielded a result of 39.8 per cent. recoveries, and intubation 36.2 per cent. recoveries; in secondary diphtheria, tracheotomy gave 17.3 per cent, of recoveries and intubation 18.3 per cent.; or in all 38.1 per cent. recoveries for tracheotomy and 34 per cent. for intubation, and Ranke then expressed the opinion, that with the gain of skill in the performance of this operation, the statistics of the results of intubation would be materially bettered.

Indeed as it is, when performed during the first year of life intubation gives a rate of recovery of 20 per cent., against 6.8 per cent. for tracheotomy.

The utility of O'Dwyer's operation does not end with croup and diphtheria. The brief histories of the following cases will illustrate this. Thus Annaudale reports a case of suppurative inflammation of the thyroid cartilage which rendered breathing almost impossible. Intubation was performed and the patient's breathing at once became easy. Subsequently the abscess was opened under chloroform anæsthesia and a large quantity of pus evacuated. The result was a speedy recovery. The same author reports a case of malign tumor, which had grown fast to the larynx and trachea. During the operation for the removal of the growth the patient became asphyxiated. Tracheotomy offered unusual difficulties in the case, and therefore intubation was performed. Breathing at once became easy and the operation was successfully concluded. Again, a child of five years, took a drink from a kettle of boiling water, and soon—in consequence of the scald—had great difficulty in breathing and became dyspnœic. Intubation was performed and recovery resulted.

These and similar cases, many of which could be cited, clearly show the value of the method in emergencies. Macewen performed intubation successfully in a case of œdema of the larynx, in a child of five, allowing the tube to remain in place for five days without harm or inconvenience.

Regarding the further indications for intubation, we may justly consider the suddenly appearing respiratory difficulties not infrequently met with in syphilis. These may be caused either by condylomata, subglottis, laryngitis, gummata or perichon-

dritis. Leffert has reported a case of syphilitic laryngeal stenosis—caused by the presence condylomater in the larynx—in which the difficulty in breathing occurred so rapidly that suffocation seemed imminent. Intubation gave complete relief. The tube was allowed to remain *in situ* for three days, and upon its removal the tumors were found to have greatly decreased in size. No subsequent difficulty in breathing was experienced.

The histories of a number of similar cases, collected from the reports of various continental writers, lie before us, but lack of space forbids our repeating them. The operation has also been of signal service in pseudo-croup, avoiding the necessity of tracheotomy, as is shown by the history of a case reported by Dr. A. Rosenberg.

In chronic stenosis the operation offers still better results than in acute cases, and in such the procedure is absolutely without danger. Among the most frequent causes of chronic stenoses of the larynx, are syphilis, scleroma, diphtheria, tuberculosis, possibly leprosy, and also traumatisms. In short, in all cases where from any cause, either traumatic or pathological, there is a deformity or contraction of the larynx, rendering breathing difficult and asphyxia imminent or possible, intubation is indicated as the most rational procedure for obtaining relief. Naturally when performed for the relief of symptoms resulting from syphilis, a specific treatment for the latter disease must be simultaneously resorted to.

Rosenberg reports cases in which the mental impression induced by the treatment, resulted in recovery. This was especially noticeable in a severe case of hysterical aphonia, but in considering such cases we are apt to lose sight of its real value in more acute ailments, however, when as in the above, the case assumed so severe a type that the patient had been brought to a hospital for the purpose of having tracheotomy performed in order to gain relief from oncoming asphyxia, the advantages of the simpler treatment are obvious.

In closing this necessarily fragmentary review of the operation of intubation, we deem it unnecessary to draw any lengthy conclusions. It has been our endeavor to portray the present status of the operation with impartiality, and it is for our readers to form their own conclusions as to its merits, as well as its advantages or disadvantages compared with tracheotomy.

CORRESPONDENCE.

PRIORITY IN THE USE OF ARSENITE OF COPPER.

ED. MEDICAL AND SURGICAL REPORTER:

SIR:—Knowing the dangers which surround one who may lay claim to the discovery of any new remedy, I have refrained from making any such claim in regard to arsenite of copper or any other medicament. I was advised that it was a useful remedy in the treatment of "cramp colic," and with that as a basis, I have extended its use to allied disorders, and am still studying its wonderful properties, much to my satisfacfaction. I have serious doubts as to the policy of publishing my later experience—because no one would believe me. My present object is to call the attention of the readers of the REPORTER to an extract from a letter received from Dr. George A. Boyle, of Louisburg, Kansas, under date of August 28, 1889, which is calculated to shed some further light upon the priority of the use of arsenite of copper.

Dr. Boyle writes: "It may perhaps be interesting to you to know how I first learned of it (arsenite of copper) as a therapeutic agent in bowel affections. I have a friend, Dr. John Wherrell, living in Kansas City, Kansas (No. 13 Mather Street), who visited me a short time ago. He is House Physician and Surgeon to the Sister's of Charity Hospital of that city. There is an old physician, Dr. Fairchild I think, practicing in Kansas City. He is an old man, some eighty or eighty-five years of age, and a friend of Wherrell's. This old doctor never writes a prescription, but carries all his own remedies, and 'doses out' at the bedside. He is eminently successful, too.

Wherrell having had some very obstinate cases of cholera morbus and allied affections, one day asked the old doctor what *he* used in such cases. The old man replied, 'Arsenite of copper.' Wherrell had heard that the

old man *never failed* in these cases, and asked him how he used it. The old doctor replied that he took 'about so much,' indicating it by showing a small portion of the point of his pocket-knife blade; that he took about ten times as much sugar and ground and triturated them thoroughly together, and then gave 'about so much,' again indicating an infinitesimal amount on the point of his knife-blade, 'every ten or fifteen minutes until relief was obtained,' adding that it 'did the work *every time.*' Wherrell asked how he came to use it, and in reply, he said, 'Oh, I don't remember; I learned to use it in the South, thirty or forty years ago.' Wherrell had great confidence in the old doctor, but not confidence enough in himself to measure, or rather, guess the 'so much,' of so toxic a remedy, so he let the matter drop until he saw your article in the *Gazette,* a short time after his talk with the old doctor.

Wherrell, at once, upon reading your article, had his son, a drug clerk, triturate 1 grain with 100 grains of sugar of milk, and divided it into 100 powders as you directed. He has since used it in a number of hospital cases, and with *invariable* success.

Dr. Hidden, of Centralia, Kansas, is one of the ablest doctors in the State, and was a partner of Dr. Fairchild for some ten or fifteen years. Hidden says that Fairchild's veracity is *unquestionable.*"

Comment from me will be unnecessary.

Very truly yours,

JOHN AULDE, M. D.

Philadelphia, July 28, 1891.

BOOK REVIEWS.

TEXT-BOOK OF CHEMICAL PHYSIOLOGY AND PATHOLOGY, by W. D. Halliburton, M. D., B. Sc., M. R. C. P.; London, Longmans, Green & Co., 1891. Received through P. Blakiston, Son & Co.—pp. 875. Price, $9.75.

The best English or American book upon physiological and pathological chemistry for text-book purposes has been that of Charles. There has been a distinct need, however, for a work which, based upon a chemical foundation, should apply that subject more closely to the actual processes of physiological and pathological changes; in the fulfilment of this demand the present volume bids fair to find ample excuse for existence. It is true that the substance of the book is even more fully presented in certain German publications; but as a work for the physician who wishes to consult in relation to the processes he is meeting and for the average student of advanced medicine, Halliburton's work is very satisfying. The book is divided into six principal parts, dealing respectively with methods of research and analysis, the chemical constituents of the organism, the tissues and organs with their functions, alimentation, excretion and general metabolism. The first portion of the volume, treating of analysis and the technique of research in the directions covered by the volume, is perhaps more brief than would have been expected, although the chemical feature of the book is from the title to be looked upon as merely a means to an end; this meagreness is, however, fully made up in the text, where special technology is mentioned in connection with the subject in hand. The second portion takes up the subject of the various proximate principles, inorganic and organic of the organism, the proteids, the carbohydrates, albumenoids, etc.; it is interesting to note the clearness of the presentation of ptomaines and leucomaines, subjects which from the nature of things are very apt to be complicated. But brief mention has been made of the toxalbumenous compounds which arise from bacterial activities; it is probable that upon this question the rapidly growing interest and knowledge will in a short while leave much to be desired in the book. This cannot be accounted a fault, however; a work upon such an extended subject is bound to rapidly grow stale upon some one or more particulars. In the third portion of the volume, dealing with the study of the tissues and organs and their functions, the fullest purpose of the book is shown and its excellence rapidly grows upon one following the development of the text. While the effort is a chemical one, the author has skilfully made the chemical sections depend for their interest upon immediate reference to the other physical and clinical phenomena of the subjects, such as more practically bear upon the attention of the student. This character of the work obtains through the rest of the volume; although in the latter portion, as in the chapter upon excretion the author loses much of his grasp as a physiologist, attending more particularly to the chemical phases of his subject. The book cannot be criticized as an original production; no works of this nature can, as they are necessarily really compends of knowledge, the result of the labor of hundreds of investigators. This knowledge has been culled from a great mass of matter and has been fully criticized heretofore and its truth or credibility granted. The book-

maker cannot as such, alter a single portion of his matter, nor can he in conscience escape from the truths which it implies; that only for which he is responsible is the completeness and manner of presentation. Herein the work of Halliburton is commendable; it cannot be said that to bring into prominence his own views he has warped or overlooked those of others. Taken as an entirety the work is decidedly clear and full. There are here and there, of course, minor errors of omission and too of commission but they do not mar the real effort as they are invariably in connection with side lights. In the discussions which properly belong to the book and upon which its existence rests, the book is concise and correct. It might have been expected in a work which has treated so fully of the blood in all its chemical, physical and clinical aspects, that some mention at least of the physico-chemical peculiarities of the leucocytes in leukæmia and allied diseases should have been made; none, however, appears. So, too, in the section upon general metabolism the subjects of heat production, heat regulation, the production and preservation of energy, and others would probably merit fuller and closer attention. As already stated, however, in general the material is clean and complete, and for the class for whom it has been written the book must certainly fill a demand.

PERISCOPE.

THERAPEUTICS.

ULYPTOL.

Ulyptol is the name given to a preparation brought forward by Dr. Schmeltz, of Nice. It has the following composition:

℞

Salicylic acid	6 parts.
Carbolic acid	1 part.
Essence of eucalyptus	1 part.

The mixture possesses an aromatic odor and a burning taste. It is almost insoluble in water, but easily soluble in alcohol, chloroform, ether, alcohol and glycerine, and also in alkaline and ammoniacal solutions. It is, according to Dr. Schmeltz, a most excellent antiseptic, and especially useful in the dressing of wounds.—*Journal de Méd. de Paris.*

PYOKTANIN IN THE TREATMENT OF CANCROIDS.

Dr. von Sehlen, in a recent number of the *Monatshefte für Prakt. Dermatologie*, reports a remarkable case of cancroid which was rapidly and completely cured by the application of pyoktanin in powder form.

The case was that of a man, seventy years old, with a cancroid of the cheek of about the size of a quarter of a dollar. The disease had been treated for a long time with resorcin without any favorable result; then the analine dyes, as recommended by von Mosetig were tried.

The powdered pyoktanin was directly applied in substance and the surface protected with a plaster. The treatment at the outset proved almost unbearably painful, but the pain was somewhat alleviated by applications of solutions of cocaine and antipyrin and dusting iodoform and boracic acid on the cancroid. After five days' treatment a marked lessening of the discharge, and a general improvement in the appearance of the ulcer had taken place. The application was at first renewed twice, and later only once a week. The edges of the cancroid began to dry up and soon nothing but a slight scar remained.

THE TREATMENT OF ACUTE ANGINA.

In the *Journal de Médecine* for April 10, 1891, Dr. Capart publishes the following methods of treatment which he employs in different forms of angina. In acute suppurative tonsillitis he causes the patient to suck small pieces of ice and orders 20 grains each of powdered salol and milk-sugar to be divided into six powders, three to be taken each day; or an equivalent amount of salol may be made into an emulsion with gumarabic and given according to the same directions. In addition, he prescribes a gargle composed of 15 grains of salicylic acid, 7½ grains of acetate of sodium in 9 ounces of distilled water, flavored with a little syrup. As a prophylactic measure against the return of abscess in the tonsils, he advises the patients for at least a month to use a gargle of a weak solution of alum containing a few drops of carbolic acid, or the following gargle may be employed:

℞

Crystallized carbolic acid	1 drachm.
Absolute alcohol	5 drachms.
Essence of mint	16 minims.

Of this solution 10 drops are added to half a tumblerful of water, and used as a gargle morning and evening. In simple catarrhal angina he prescribes the following potion:

℞

Borax	60 grains.
Salicylate of sodium	30 grains.
Decoction of marsh-mallow	6 ounces.

Flavor with syrup. If a cure does not take place within 24 or 36 hours he then has recourse to a slightly astringent gargle, such as the following:

℞

Calcined alum	40 grains.
Alcohol and pure glycerin, aa	2½ drachms.
Water	10 ounces.

To be used as a gargle four times daily. He cautions in the strongest terms, against the use of concentrated solutions of tannin or alum.—*Ther. Gaz.*

ON THE THERAPEUTIC USES OF MEDICATED SUPERFATTY SOAPS.

Dr. Carblom, of Riga, reports a series of therapeutical experiments with the different sorts of Eichhoff-Unna's medicated "superfatty" soaps (cf. Drs. W. Allan Jamieson's and B. Dott's paper in the *British Journal of Dermatology*, June, 1890, p. 172; also Dr. B. H. Paul's, *ibid.*, March, p. 81), applying them in one of the following four ways:—1. A warm lather was rubbed into the skin, and after a short time washed away; 2. The lather was rubbed into the skin in a similar manner, but removed by means of wiping with a dry towel or linen; 3. The parts were covered with a thick layer of the lather and allowed to dry; 4. The lather was similarly thickly painted over the area, and then covered with some waterproof, and thus Dr. Carblom has come to the conclusion that a superfatty:

1. *Resorcin-and-salicylic-acid soap* proves especially useful in parasitic cutaneous affections, associated with hyperplasia of the cuticle—such as parasitic or seborrhoic eczemas, psoriasis, acne, ichthyosis.

2. A *salicylic-acid–resorcin–and–sulphur soap* is indicated in similar affections, but more especially in such cases as are characterized by a more chronic course of the cutaneous inflammation, deeper hypertrophy, and desquamation.

3. A *salicylic-acid-resorcin-sulphur-and-tar soap* is serviceable in the same category of affections, but particularly in common psoriasis.

4. All the three afore-mentioned soaps can be also strongly recommended in favus and tinea tonsuran.

5. A *quinine soap* gives good results in pityriasis versicolor, and in the intertrigo eczemas of children. An after application of some bland powder is advisable.

6. A 3 per cent. *hydroxylamin soap* proves beneficial in lupus, tinea tonsurans, inveterate cases of psoriasis and eczema, and, occasionally, even in lepra and lues. The application usually causes some burning pain.

7. A 5 per cent. *iodoform soap* affords a good means for cleansing and stimulating indolent ulcers.

8. A *creolin soap* can be employed with advantage in scabies, impetigo contagiosa, intertrigo, as well as in bromidrosis. The lather should be firmly rubbed into the affected parts several times a day.

9. An *ergotin soap* is of service in simple rosacea, frost-bites, and for treating congested cicatrical areas of any kind.

10. An *iodine soap* can be successfully used (*a.*) as a resorbent in cases of goitre, or superficial granular enlargements; and (b.) as a parasiticide in cases of tinea tonsurans, pityriasis versicolor, psoriasis, etc. It should be kept in mind, however, that the preparation possesses a powerful irritant action, and hence its application should be from time to time interrupted, and a zinc starch powder employed instead.

11. A *salicylate-and-creasote soap* produces excellent results in lupus. It may be used either as a wash to the part, or in the form of lather (protected with a waterproof dressing), or the soap application may be alternated with some surgical procedure.

In comparison with plasters, salves, pastes, etc., the use of the soaps is said to be both more convenient and a good deal cheaper. On the whole, the introduction of the preparations can be safely termed an important advance in dermato-therapeutics.—*Brit. Jour. Derm.*

ON THE CONTAGIOUSNESS AND TREATMENT OF COMMON WARTS.

Dr. J. F. Payne, in the *Brit. Jour. Derm.*, says: Common warts, including under this name the so-called Verruca vulgaris, and Vurruca plana (which differ only according to the part of the skin on which they occur), but excluding the senile pigmented warts and the pointed condylomata, of which the origin is not so clear, appear to arise by implantation of some contagious material at one or more points of the skin, usually on exposed parts. This implantation may of course be favored by want of cleanliness, but warts are certainly not produced, as is sometimes asserted, by this cause alone. There is also some idiosyncrasy which may cause either special predisposition or immunity; for while some persons, especially children, are very liable to warts, others, though liv-

ing under precisely the same conditions, never suffer from them. From the original wart or warts thus produced others may be set up by local inoculation just in the immediate neighborhood, afterwards perhaps in more distant parts, such, for instance, as the other hand, or the face; but often the affection has a strict local limitation; the process of extension is arrested, and the warts die off and disappear spontaneously without any apparent cause.

At any period, he believes, that communication to another person is possible by ordinary contact, or possibly by handling the same objects; though this does not occur constantly, nor perhaps very often, since a somewhat close contact appears, as in the case of scabies, to be necessary. The familiar fact that warts occur in many children or young persons in the same family, school, or place of business, seems difficult of explanation on any other hypothesis. The same hypothesis, taken in connection with the fact of their frequent spontaneous disappearance, explains also some of the curious popular superstitions on this subject: such as that warts can be conjured away by charms, or got rid of by sale to a willing purchaser. The belief in charms is of course supported by the occasional spontaneous vanishing of warts after some ceremonies have been gone through, and the supposed transference by sale from one person to another will rest upon the not impossible coincidence that they may be fading away from the seller at the time that the contagion has already been transferred to the buyer. Such coincidences impress the imagination, while the far more numerous negative instances or failures are forgotten.

There is even less difficulty in accepting the belief that fresh warts are produced by local inoculation of some pathogenic material derived from an existing one. If the spread of these structures in any patient be carefully watched, it will be seen to be governed by some such law. The causal or genetic connection is sometimes marked by the different appearance of warts on different regions. For instance, from the back of the hands they may be, in children, transferred to the face; though, being in the latter situation, smaller, less conspicuous, and less horny than on the hands, they are often thought to be of a different kind. Of course it is quite possible also for the first inoculation to occur on the face.

We do not as yet know of what the infective material consists. Micrococci may doubtless often be found, but they are so commonly present in inflamed or hypertrophic patches of skin, that they can hardly, without further proof, be admitted as a cause. The popular belief is that inoculation takes place through the blood, if the warts are made to bleed, and there seems to be some ground for supposing that blood may be a specially good carrier of infection.

With regard to the local treatment of warts, there is little new to be said. Collodion of salicylic acid, which is now become quite a popular remedy, seems generally the best application, but it does not always succeed. Various caustics and acids are also used. The commonest mistake is that to attempt to destroy the wart once for all by some powerful caustic. This process is often painful, and if it succeeds is apt to leave a scar. A better method is to apply some light caustic, such as acetic acid, either concentrated or diluted to half strength, several times a day; and in this lies, Dr. Payne believes, the main secret of successful treatment. Of internal treatment by sulphate or carbonate of magnesia, recommended by several authors, and lately by Radcliffe Crocker, Dr. Payne has no personal experience.

THE THERAPEUTICS AND PHYSIOLOGY OF BLEEDING.

According to Dr. Pye-Smith venesection is indicated in: 1. Cyanosis with distension of the right side of the heart, whether from pulmonary or other obstruction to the circulation. 2. Intense pain of aortic aneurism. 3. Uræmic and prolonged epileptic convulsions. It is contra-indicated in fevers, inflammatory disorders, acute pneumonia, hæmorrhage and apoplexy.

The physiology of venesection has recently been studied again by Professor I. M. Dogiel (*Vratch*, in *London Medical Recorder*). His experiments were conducted mainly upon dogs and he comes to the following conclusion: 1. Dogs can survive, without any permanent injury to their health, after having lost from one-seventh to one-half of the animal's total mass of blood at a time. The extraction of two-thirds of the total, however, is invariably followed by death. 2. Bloodletting manifests a sharply pronounced influence on the frequency of the cardiac beats in the case of a moderately large depletion (from one-seventh to one-third of the total quantity of blood), the cardiac action becomes accelerated, while after larger losses it either quickens or becomes slower. 3. Bloodletting also produces a marked effect on the rhythm and energy of the cardiac contrac-

tions (as details). 4. Mild bleedings (made by means of ten or fifteen leeches) either do not alter the arterial tension, or slightly raise it. More or less considerable arterial bleedings either do not affect the blood-pressure, or are followed by a fleeting initial fall with a subsequent rise, while venesections commonly lower the tension. 5. After moderate depletions "the pulse-wave acquires a periodical character." 6. In the beginning of a bleeding the bodily temperature slightly rises, then sinks about 20° F., and afterward again gradually rises. 7. On repeated depletions (made every three or four weeks) the bodily weight at first increases—and that sometimes "very considerably"—but later on begins to sink. 8. The same holds true with regard to numerical strength of red blood-corpuscles. 9. On the post-mortem examination of animals dying from bleedings the most prominent feature proves to be a fatty degeneration of the heart and other striated muscles, as well as various viscera. In the course of a discussion, Professor A. B. Vogt and Dr. S. M. Shtcherbakoff have stated that, according to their experiments, bleedings do increase not only the number of red blood-corpuscles, but also the proportion of hæmoglobin.—*Med. Rec.*

THE EFFECTS OF STRYCHNINE ON THE STOMACH.

The effect of nitrate of strychnine on the functional activity of the stomach has been investigated by Dr. Gamper. He found that strychnine increased the amount of gastric juice secreted, the general acidity, and the quantity of free acid in the secretion. It also restored the absorption from the stomach, and strengthened the mechanical movements. Its effect continued for some time after its administration had been stopped. Dr. Gamper declares strychnine to be the most effective of all drugs in the treatment of chronic alcoholism.—*Lancet.*

THE VALUE OF ARISTOL.

In the *Centralblatt für die Gesammte Therapie* for May, 1891, Dr. Weissblum reports the results of some experiments which he made with aristol in the treatment of eczema, psoriasis, and favus. As a vehicle, he employed either olive oil, vaseline, or lanolin. With vaseline, he employed the aristol in ten per cent. strength; in a few cases in twenty per cent. The author's experience seems to show that in severe cases of psoriasis nothing whatever can be expected of aristol, and, after four to ten months' treatment with aristol, other remedies must be finally resorted to. In light cases treatment will be necessary for from two to five weeks, although even then the effects are by no means as satisfactory as obtained with pyrogallol. In one case, on the fourth day of treatment with aristol, slight symptoms of irritation appeared, consisting of redness and swelling. Three cases of psoriasis were treated with aristol in ten per cent. strength and with hydroxylamine. Hydroxylamine had to be given up in the second week on account of the irritation and pain which its employment occasioned, and although the aristol was persisted in from five to eight and eleven weeks, not the slightest influence was obtained from its administration. Pyrogallic acid had to be employed in all cases. The author concludes as regards psoriasis that where a speedy cure is a matter of indifference aristol may be used. Eight cases of eczema were treated with aristol, in all of which the aristol appeared to be satisfactory, while three cases of favus and one of alopecia areata were treated with aristol with no more effect than could be expected from the vehicle in which it was administered. So also a case of syphilitic gummatous ulcer was treated for three weeks with powdered aristol without the slighest influence whatever.—*Ther. Gaz.*

MEDICINE.

ALBUMINURIA IN PERSONS APPARENTLY HEALTHY, AND A CONSIDERATION OF ITS RELATION TO LIFE ASSURANCE.

Dr. William B. Davis, in an article in the *N. Y. Med. Record*, says that he thinks we will be warranted in accepting the following rules for guidance in the consideration of candidates for life assurance having albuminuria, viz.:

General Rules.—1. There should be nothing in the family history indicative of heredity of Bright's disease, and there should be no symptom of renal disease in the personal history except albuminuria.

2. The candidate should be under forty years of age, in good health, and there should be no history of gout, rheumatism, syphilis, lead poisoning, nephritis, intemperance, chronic dyspepsia, or dropsy.

3. There should be no indication of hypertrophy of heart or increased arterial tension,

no accentuation of the aortic second sound, and no palpitation or dyspnœa.

4. There should be no retinal changes.

5. The color, density, and quantity of the twenty-four hours' urine should be normal, or it may be darker in color and heavier in density.

6. The specific gravity of the twenty-four hours' urine should not be below 1-030. It may range from 1.015 to 1.030.

7. The precipitated albumin should not exceed one-eighth of the urine.

8. There should be a period of the twenty-four hours when the urine is free from albumin.

9. The urine, as a rule, should contain no tube-casts. When, however, the specific gravity and quantity of urine are normal, the presence of a few hyaline casts have no serious import.

When the above conditions have been met, and we are convinced of the ability of the medical examiner, and are satisfied with the completeness and carefulness with which the investigation of the case has been made, I think we can safely approve the candidate for a short endowment policy.

To a person who has just passed the above gauntlet and been subjected to a rigid medical examination, this action will doubtless appear illiberal, but until the clinical significance of albuminuria in persons apparently healthy has been finally determined by observations upon one full generation, we cannot, and probably ought not, to expect life assurance companies to do any better for them.

ORIGIN AND ROLE OF PUS CELLS.

Professor Ranvier made an interesting communication at a recent meeting of the Academy of Sciences on the origin and signification of pus cells. He said that for some years past histologists generally were agreed that the cells of pus were none other than the white corpuscles of the blood, which had emigrated from the vessels at the time suppuration was set up. He found it difficult, however, to believe that the blood could yield in this way, and in a time comparatively short, the enormous quantity of pus found in many pathological conditions, such, for example, as the purulent infection of wounds, accidental and operative. That the white cells do emigrate in the manner generally accepted he had no doubt. This takes place under normal physiological conditions, while it is still more pronounced in certain pathological states not ending in actual inflammation, in the process of which it is of course abundantly evident. What his experiments led him to establish, however, was that pus cells had also quite another origin—viz., the transformation into lymph cells of clasmatocytes, elements derived from migratory cells, which under the influence of irritation revert to an embryonic condition and proliferate rapidly. As to the *role* of the pus cells, M. Metchnikoff has shown the importance of lymphatic cells in the combat of the organism against microbes. In simple inflammation determined by caustics, or other irritant agents, their *role* is not less important. They eliminate the dead elements, and thus prepare the way for the processes of regeneration.—*Brit. Med. Jour.*

PHENACETIN IN INFLUENZA.

I desire to draw the attention of the profession to the beneficial action of phenacetin during the first stage of influenza. Its action is prompt and striking, so that many patients declare they have derived more benefit from the "powders" than from anything else. It rapidly cures the headache which is such a distressing symptom at first, helps to reduce the temperature, and mitigates, but does not entirely remove, the aching of the limbs, a few doses of salicylate of sodium effecting its final removal. I give the phenacetin in 5-grain powders, repeated every four hours, until the headache and other pains cease. I have used phenacetin largely in a variety of conditions, and consider it is unrivalled as an analgesic. It seldom fails, it is comparatively cheap, tasteless, and, as far as I can see from a tolerably extended experience of it, is totally free from the unpleasant after-effects—depression of heart, etc.—sometimes caused by antipyrin and other drugs of its class. Insolubility is its sole drawback.—John P. Henry.—*Brit. Med. Jour.*

THE VALUE OF THE TONGUE AS A RESPIRATOR.

J. M. Elborough writes as follows:

It is not generally known that nature has provided each of us with the best respirator always at hand in the tongue. For years I have personally relied on this alone, and have recommended this proceeding to many patients. When facing a cold east wind, or breathing quickly the night air, I never quite close my mouth, but purposely keep the lips a trifle parted, and at the same time curl up my tongue towards the roof of my mouth until the tip reaches as far back as

the soft palate, and I gently press the arched under surface of the tongue in some degree against the hard palate (a little practice soon makes this easy to do). The cold air then, as it enters the mouth, strikes against the under surface of the tongue, as well as the floor and sides of the mouth, and is made to pass in a somewhat circuitous manner between the sides of the tongue and the buccal mucus membrane of the pharynx, being thereby warmed in its course, so that by the time it reaches the larynx it is nicely rid of chill, and does not excite cough and catarrh. At the same time a certain quantity of air, of course, finds its way through the nasal passages to the chest, and it is obvious that a larger quantity of cold air can be effectually warmed by this method of procedure than by relying on either the nose or mouth alone. That the large blood-supply of the tongue renders this organ an excellent air warmer must be obvious to all.—*Lancet.*

ESSENTIAL SPASM OF THE CARDIAC ORIFICE OF THE STOMACH.

Dr. Stefano Mircoli, in speaking (*Lo Sperimentale*, April 15th, 1891) of spasm of the cardiac orifice of the stomach, points out that the symptom is due not to stimulation, but to the want of it, since if the vagus is divided the opening remains closed, unless the peripheral end of the cut nerve is artificially stimulated. Schiff has shown that there is a special twig from the vagus which regulates the opening of the cardia. The cardia is richer in ganglia than the stomach itself, there being twelve in the former and only ten in the latter; this richness in nervous material almost entitles it to be called the "brain" of the stomach. The different parts of the cardiac orifice are functionally independent of each other, and one-half may be in a state of contraction while the other is relaxed. Mircoli relates three cases with the object of showing that in some persons, otherwise perfectly healthy, the susceptibility of the cardia to nervous impressions may be so marked as to amount to disease, and may be inherited as a diathesis. The first case was that of a man, aged 50, who in May, 1885, suffered from melæna (suggested to have been due to "abdominal vasomotor paresis"); the bleeding recurred several times, and the patient died of exhaustion in the following September. Among other symptoms, intermittent spasm of the cardiac orifice was observed; when the patient was most weakened by loss of blood, solid food did not reach the stomach, and even liquids partially failed to enter it. On passing a bougie, the œsophagus was found to be unobstructed, but firm resistance was encountered at the cardiac orifice; this sometimes yielded, but at other times could not be overcome. The constriction always vanished spontaneously in a few days. A son of this patient, aged 24, went to bed one night in 1888 after a hearty supper; in the morning he could not swallow, everything taken, whether solid or liquid, being stopped at a point corresponding to the cardia, and then thrown up. The spasm began to yield after some hours, to energetic counter-irritation over the epigastrium and inunction with "oil of hyoscyamus," and finally disappeared on the following day. A brother of this patient, aged 27, suffered from similar symptoms in 1890, under the mental stress caused by an impending lawsuit; the condition persisted more or less for more than a month, and finally ceased when he had won his case. Mircoli thinks that in persons of neurotic temperament such a condition might, by frequent repetition, lead to true stenosis of the cardiac orifice, and he quotes a private letter received by him in 1885, from the late Professor Loreta, in which that distinguished surgeon says: "Of the nine divulsions which I have performed for stenosis of the cardiac orifice, three were caused by contraction with subsequent fibrous degeneration. In the history of these patients (all of whom were women) hysteria was a prominent element; this was accompanied by dyspeptic phenomena, at first intermittent, but after some years becoming continuous and so preponderant as to induce agonies of hunger and thirst. There was no cause or circumstances which could lead one to conjecture sclerosis or cicatricial contraction. This is a chapter of pathology which requires to be illustrated and extended, so that medical practitioners may be forewarned against catarrhs, gastritis, cancer, etc.—diseases which sometimes are merely secondary to purely mechanical conditions."—*Brit. Med. Jour.*

NICOTINE PSYCHOSIS.

According to Dr. Schroff, *Wiener Med. Prusse*, the primary effect of tobacco upon the system, is excitation, the secondary, depression. It affects the entire muscular system, the heart as well as the vasomotor system. The disease called nicotinosis mentalis is a primary insanity, having a regular course and characteristic symptoms. Among

the latter are: a feeling of extreme debility and impotence, with early hallucinations, delusions and suicidal tendencies. The patient at first feels ill, is restless, easily excited, sleepless, indifferent to usual occupations and more or less depressed; afterwards hallucinations of sight, hearing and of general sensation set in with much palpitation and pain about the heart. Later in the course of the disease the hallucinations become more exaggerated; he has visions of angels, heaven and hell, is excitable and boisterous. The paroxysms of excitement are periodical, lasting two weeks or more, with intervals of quiet. In the beginning of the disease the patient is gloomy and restless; later on, and as it becomes chronic, he is more quiet and feeble-minded. Patients sometimes recover in the early stages, but never in the later ones. Dr. Kjellberg, of Upsala, has investigated the effects of tobacco in inveterate smokers and finds that they are of a distinctly injurious character. Nicotinosis mentalis is a primary disease which belongs to the group of mental intoxications. Dr. Kjellberg also speaks of a preliminary stage lasting about three months, which is characterized by general malaise, uneasiness, insomnia, depression often of a religious tendency. He divides the established disease into three stages: (1.) The patient is subject to hallucinations, fixed ideas, with tendency to suicide, depression, attacks of fear and outbursts of anger. He talks little but logically; the nutrition is impaired. (2.) Exaltation of a pleasant type is present, followed after two or three weeks by depression which, in its turn, is succeeded by a slight maniacal condition. (3.) The intervals between the attacks are shorter, the patient very restless and the intellect and memory impaired. He observes what is going on, but is taciturn and indifferent. The prognosis is good before the third stage, but after that unfavorable. The treatment consists mainly in abstinence from the use of tobacco, with nutritious diet.

SURGERY.

THE POINT OF SELECTION IN PARACENTESIS OF THE ABDOMEN.

Paracentesis of the abdomen is one of the most common, as it is one of the most ancient, of surgical procedures. The technique of its performance is based upon well established principles, known to every practitioner, but there is still some difference of opinion as to the place best adapted for the puncture. Some surgical authorities recommend the median line as most suitable for paracentesis, while others express a preference for Monro's point of selection, which is a point situated in the center of a line drawn from the umbilicus to the anterior superior spinous process of the ilium. Aside from the possibility of wounding the intestines or bladder, the chief danger in this operation is injury to the epigastric artery, and it has been claimed that this accident may be prevented by making the puncture at the spot selected by Monro. That this claim is not well founded is evident by a case recently reported by Dr. Frzebicky in the *Archiv für Klinische Chirurgie*, where a paracentesis performed at the latter place for an inoperable ovarian cyst was attended by so profuse a hæmorrhage from the epigastric artery, that it proved well-nigh fatal. This accident led the doctor to investigate the subject, and as the result of numerous experiments on the cadaver, he arrived at some conclusions which are of practical interest, both to the surgeon and physician. The investigations, which were carried out with unusual care, demonstrate the fact that, on anatomical grounds, the liena alba is the most suitable place for paracentesis, provided, of course, that no contra-indication, such as adherent intestines, exists. By performing the operation in the median line, all danger of wounding important parts is avoided, although the puncture should not be made too close to the symphysis pubis to prevent injury of the bladder. It is also necessary to keep exactly in the middle since, in rare instances, a large branch of the epigastric artery passes along the side of the linea alba, injury of which may prove fatal. Although in the majority of cases, where the puncture is made at Monro's point of selection, the artery or its branches are not exposed to injury, there is a considerable minority where this accident is liable to arise. If, for some reason or other, paracentesis cannot be practiced in the median line, the author recommends us to select the outer half of a line drawn from the umbilicus to the anterior superior spinous process of the ilium.

If the artery is injured by the trocar, it may be compressed by packing the wound with iodoform gauze, but if the bleeding is at all profuse, no time should be lost in ligating the vessel. Hence the author judiciously suggests that, in cases where the puncture is made outside the linea alba, the surgeon should always be provided with the instruments necessary for ligation. In the absence

of instruments and assistance, compression of the iliac artery may be tried, although it is frequently difficult to accomplish this procedure in a satisfactory manner.—*Internat. Jour. Surg.*

DISTURBANCES IN METABOLISM FOLLOWING LONG-CONTINUED CHLOROFORM NARCOSIS.

Chronic chloroform poisoning has been noted by Casper, Langenbeck, and Behrend, but their cases have attracted but little attention. Nothnagel, in 1866, experimented upon dogs, and after death was able to demonstrate fatty degeneration of the heart and liver.

Professor A. Kast and Dr. B. Mester refer to these early cases and to Nothnagel's experiments, and also to the much more recent experiments of Ungar, Strassmann, and others. One of them had previously investigated the influence of chloroform narcosis upon the excretion of chlorides in the urine. The chlorides were found to be increased, the animals exhibited a series of disease symptoms, and failed in nutrition and weight, in spite of the fact that both before and after narcosis they were kept upon meat food freed from chlorine. The inference is that chloroform effects a toxic disturbance of nutrition.

Kast and Mester, struck by the analogy of the excretion of the chlorides as an after-effect of chloroform-narcosis to the chlorine tissue-change in other severe disturbances of metabolism, turned their attention to the excretion of the sulphurous substances in the urine. They examined the urine of fifty or sixty women shortly after chloroform narcosis in the Freiburg gynæcological clinic, and that of ten other patients from the surgical clinic. The urine was examined qualitatively and quantitatively for sulphur compounds. About thirty control tests were made. Unoxidized sulphur was found to be increased largely. This is regarded as showing the profound effect of prolonged chloroform from narcosis on the metabolism of albumin. As to the duration of this metabolic change, the urine showed the lead reaction for sulphur in one case as early as an hour after the chloroform narcosis, which had lasted two hours; usually it is detected on the second day, and in one case it was present on the fifth day. The duration of the increased excretion of sulphur-holding substances coincides pretty accurately with the duration of the well-known reducing properties of chloroform urine.

As to the nature of the sulphur compound, Kast and Mester believe it to be cystin, or a body resembling it.

Urine, under the influence of chloroform narcosis, becomes highly acid, due apparently to the considerable quantities of chlorine, which occurs in the form of hydrochloric acid.

The conclusions of Kast and Mester are as follows:

1. Chronic chloroform poisoning, that is to say, the toxic action of large doses of chloroform, given either internally or by prolonged inhalation, is recognizable both in animals and in men.

2. It manifests itself by a fatty degeneration of the organs. There is a lessening of the body weight, an increased excretion of chlorine (Kast), and of oxygen (Strassmann), showing an increased consumption of albumin in animals. In man, as the result of prolonged chloroform narcosis, a sulphur compound, resembling cystin, is thrown off in considerable quantity. There is also a constant and more or less considerable urobilinuria.

3. In relation with the form of excretion of the received chloroform stand—(1) the reducing property of the urine through the formation of a glycuronic acid combination, and (2) the considerable increase in the acidity of the urine following chloroform narcosis.—*Zeitschrift für klin. Medicin*, Bd. lxxx., Hefte 5, 6.—*News.*

TREPHINING THE SPINE FOR FRACTURE OF THE DORSAL VERTEBRÆ.

Cases of trephining the spine are always calculated to interest surgeons, and any successful case of the kind is well deserving of being placed on record. Dr. D. N. Knox, of Glasgow, gives the notes in the current number of the *Glasgow Medical Journal* of a case of trephining the spine for fracture with dislocation of dorsal vertebræ. The patient was a pit boy, aged 13, who received a severe injury to his back through a cage having fallen upon him. On examination, much bruising of his back was found, and a very distinct projection in the dorsal region of the spine caused by a displacement backwards of the eleventh dorsal vertebræ. Urine was passed involuntarily soon after admission. There was complete loss of power and sensation in both lower limbs. The spine was trephined by the author thirty-six hours after the injury. The projecting spinous process was cut down upon, the muscles carefully separated from it, and from the spine

and laminæ of the vertebræ above. The tip of the tenth spinous process was found to be broken off, and the body of the eleventh vertebræ was broken across in a direction obliquely downwards and forwards; the upper articular processes were also fractured and displaced behind the lower articular processes of the vertebræ above. The lower vertebræ was displaced backwards fully three-fourths of an inch, and its spine was rotated as much to the right side. The laminæ of the tenth dorsal vertebræ were sawn through with Macewen's saw, and the spinal theca exposed. The latter was not opened. Small portions of the articular processes were also nipped off, and the spine being carefully extended, the displaced vertebræ was pushed back into position. The spinal canal was carefully cleaned, and as the soft tissues were so much injured, the wound was stuffed with gauze. On opening the canal pulsation was not at first felt in the cord, but by the end of the operation it could be distinctly felt. On the day following the operation, sensation was found to be perfect in both limbs, but it was the third day after the operation before the boy could move his toes. This was the sole movement of which he was capable for nearly two months. The wound was allowed to granulate on account of the severe bruising of the soft parts. The progress of the patient was steady but slow. He was first able to turn on his side by swinging round on his pelvis, then to sit up, then to raise himself on his hands and knees in bed, then he crawled on the floor, then raising himself and supporting the upper part of his body on a stool or on the bed, he rested his weight on his feet, then he began to walk with assistance, and, lastly, he learned to balance himself on his feet. The author concludes by saying that he expects before long that this training of the muscles by the boy will be perfect, and that he will have normal control over his movements.—*Med. Press.*

RESECTION OF THE PUBIS IN SUPRAPUBIC CYSTOTOMY FOR THE REMOVAL OF VESICAL TUMOR.

At the French Congress of Surgery, M. Heydenreich, of Nancy, in a paper of which an abstract is given in the May number of the *Revue de Chirurgie*, stated that occasionally on removal of a tumor from the bladder by the suprapubic method, some difficulty is experienced in reaching the seat of disease in consequence of the obstacle formed by the upper portion of the pubic symphysis. In order to overcome this difficulty the surgeon might, it is held, without compromising the solidity of the pelvic girdle, resect this portion of bone by two incisions made one on each side, beginning either within or without the spine of the pubes and carried downwards and inwards. The author practised this method in a case in which the vesical growth, notwithstanding the use of Peterson's bag, was inaccessible. The upper portion of the symphysis having been resected the operation was completed without any further difficulty. It is held that resection of the pubes does not add to the severity of suprapubic cystotomy, but that, on the contrary, it facilitates the operation and shortens its duration, and, at the same time, enables the surgeon to get beyond the limits of the tumor. Resection of the pubes, however, is not indicated in every case of removal of vesical growth. It must be regarded as an exceptional procedure, but still one which the surgeon should not hesitate to employ whenever it seems to be necessary. In the discussion on this paper it was asserted by M. Pozzi that the position of the patient advocated by Trendelenburg affords free access to almost every part of the interior of the bladder, and so in almost every case would render resection of the pubes an unnecessary and useless proceeding.—*Ont. Med. Jour.*

OPERATIVE MEASURES FOR THE RELIEF OF IMPAIRED HEARING.

In some cases of adhesions resulting from chronic suppuration of the middle ear Dench (*Arch. of Otology*, January, 1891) found good results follow operative proceedings. In one, after the reduction of inflammatory swelling on the inner wall of the tympanum he observed the stapes apparently firmly fixed by fibrous tissue. He made incisions through this material on two occasions with improvement of the hearing. In another case the upper edge of a large perforation appeared to press upon the ossicular chain. A vertical incision was made through this edge extending upwards about $\frac{1}{16}$ inch. The improvement which resulted has continued. In a third case the handle of the malleus had become adherent to the promontory, thereby fixing the ossicles. The adhesion was divided, and the hearing power was considerably increased. The tip of the malleus was, in a fourth case, drawn backwards, upwards, and inwards, and attached to the head of the

stapes by a firm band, the section of which rendered the hearing of articulate speech practically normal.—*Brit. Med. Jour.*

GYNÆCOLOGY.

INVERSION OF THE UTERUS.

Remy (*Archives de Tocologie et de Gynæcologie*, Feb., 1891) reports two cases of inversion of the uterus, each of special interest and each of important bearing on the causation of this accident. The first was that of a primipara who was delivered by a midwife. The method of removing the placenta by traction upon the cord in the axis of the inlet with one hand and compression of the fundus with the other was employed. Palpation, in order to determine the retraction of the uterus, failed to reveal the organ in its proper position in the pelvis. Suspecting hæmorrhage, she made an internal examination and discovered, within the vulva, a tumor which completely filled the vagina. The writer, on his arrival, found an inversion of the second degree. After an unsuccessful attempt at reduction by grasping the tumor in one hand and making compression with his fingers at the level of the pedicle, while he made counterpressure from without, he effected a reposition by pushing against the body of the uterus with the convex, dorsal surface of the fingers, slightly flexed, of one hand, at the same time making counterpressure with the other. When he had replaced the uterus he allowed his fingers to remain in the cavity, in order to excite contraction, and after giving an antiseptic irrigation he delivered the case over to the former attendant.

Inasmuch as there had been no adherence of the placenta and no violent traction, he concludes that the accident must have been due to some special cause. To explain this, he alludes to the important factor in uterine retraction, namely, the contraction of the uterine surface at the site of the placenta coincident with that of the rest of the uterus, in order to fill the void created by the detachment of the after-birth, and shows how, in this case, the absence of this factor played an important part in the inversion. The placental site, in this case, failing to contract, became inverted by the effect of the removal of the placenta, which acted like the piston of a pump, or, in other words, the abdominal pressure forced the lax uterine wall into the retroplacental space; the consertive influence, in such a condition, exerted by the resistance of the clots which accumulate behind the placenta, proving ineffectual.

The second case is that of a young woman, who, after her second confinement, which was normal in every respect, upon leaving her bed, suffered from a severe hæmorrhage which was repeated after a few days without apparent cause. In both instances hypodermic injections of ergotine were used successfully to control the hæmorrhage. The writer, upon examination some days later, discovered a friable tumor occupying the vagina just within the introitus. Owing to the consistence of the mass and the offensive odor of the discharge, he concluded that he had to do with a retained portion of the placenta. The attempt to remove the mass with a volsella gave rise to profuse hæmorrhage. After a more careful bimanual examination, he discovered an inversion of the second degree. This he treated by means of continuous pressure by cotton tampons covered with iodoform gauze. He explains this production of inversion, so late in the puerperal state, as follows: There was, in all probability, a retention of a small portion of the placenta which caused a local congestion at this point, under the influence of which the uterine tissues at the insertion of the placental polyp, became gradually more and more yielding until the contraction of the rest of the organ forced it through the partially dilated os.—*Univ. Med. Mag.*

OBSTETRICS.

THE VAGINAL OPERATION IN EXTRA-UTERINE PREGNANCY.

In an interesting paper in the *American Journal of Obstetrics*, April 5th, 1891, Dr. Fenger presents the following conclusions:

1. In cases where the fœtal cavity is still aseptic, the vaginal operation exposes the patient to danger of sepsis in the fœtal sac, which cannot be guarded against. Abdominal section gives far better means of protection against septic infection.

2. Hæmorrhage from the placenta cannot be controlled by the vaginal operation. By abdominal section, on the other hand, ligation of the internal spermatic and uterine arteries, as devised by Olshausen, might in some cases be accomplished as a means of checking hæmorrhage from the site of a removed placenta, in the territory supplied by these vessels. Abdominal section further

permits of ligature *en masse* of the bleeding portions when the placenta has been divided at the place of incision.

3. Delivery of the child at full term is usually difficult, and thus dangerous to the mother, by the vaginal operation, but easy by the abdominal operation.

4. If the fate of the child is to be considered, the vaginal operation must be abandoned, and replaced by abdominal section.

5. When suppuration has set in, in an extra-uterine pregnancy presenting low down in the small pelvis and the placental circulation has ceased, the vaginal operation may be considered in comparison with the abdominal operation.

6. The vaginal operation is strongly indicated in old suppurating fœtal sacs, with disintegrated fœtus presenting in the vagina.

ABSENCE OF UTERUS.

M. Delageniére (*Union Médicale*, April 7, 1891) read before the recent meeting of the French Surgical Congress, a case where a woman, aged 23, was entirely destitute of uterus and vagina. The presence of the ovaries was manifested, it is said, by periodical attacks of pulmonary congestion. Abdominal section was performed, and the ovaries, which lay in the iliac fossæ, were removed. Twelve days afterwards it was thought advisable to form by dissection a vagina, lined in part by the mucus membrane of the vestibule and in part by two large cutaneous flaps turned in from the gluteal region. Since the operation the patient's health had remained good. The attacks of congestion of the lungs ceased completely. The artificial vagina did not contract. M. Delageniére found that the ovaries were affected with sclerosis and cystic degeneration.—*Brit. Med. Jour.*

PÆDIATRICS.

INUNCTIONS AFTER SCARLET FEVER.

A correspondent who does not seem to possess much sense of logic, narrates the case of a patient convalescing from scarlet fever, in the course of which he was astonished at the early and extensive peeling that occurred, till one day, noticing the patient to be listless, with dry, brownish tongue, it occurred to him to try and fathom the significance of these symptoms. He found the urine smoky, and he elicited from the nurse that she had been using 1 in 40 carbolized oil by way of inunction. This having been discontinued and plain olive oil substituted the symptoms disappeared and all went well. To most practitioners this experience would appear in the light of a warning not to make use of an inunction which had proved itself to be possessed of toxic properties. Not so the correspondent in question. On the contrary, he infers from a review of the facts of the case, that it would be a good plan to use the carbolized oil, and to stop it immediately if any untoward symptoms occurred. Now we will venture to doubt the propriety of using oleaginous or, indeed, any inunctions, at all after scarlet fever. They must, perforce, seriously interfere with the eliminatory functions of the skin just at the time when the partial suspension of these very functions is throwing a strain upon the kidneys which not unfrequently determines a serious degree of congestion. To deliberately throw a further burden on the kidney by necessitating the excretion of a toxic and irritating body, savors of recklessness, and is certainly not to be commended. Our object should be to facilitate but not to precipitate desquamation, and this may be safely and adequately provided for by warm baths followed by friction.—*Med. Press.*

HYGIENE.

OF PSOROSPERMS AND THEIR IMPORTANCE.

The subject of psorosperms is at present exciting so much interest among pathologists in this country and in France, that it will be well to review the present state of our knowledge of these organisms. Psorosperms, also called coccidia and pseudonaviculæ, are classed by most zoologists amongst the protozoa or lowest class of animals, though Robin and a few other writers consider them algæ. Assuming that they are protozoa it appears probable that they form a stage in the life-history of the Gregarinda. Psorosperms usually occur massed together in cysts whose distribution in the animal kingdom is very wide, for they are found parastic in connection with the alimentary canal and liver of the higher vertebrata, in nearly all the organs of fresh-water fish, and in many of the tissues of the lepidoptera, orthoptera, and arachnids. They are most readily seen, however, in the livers of ill-fed rabbits, where they occur as small whitish nodules. In man, Dr. Delépine—who in a recent paper read before the Pathological Society of London

showed how carefully he has studied the subject—says that psorospermial cysts have been described as occurring in the alimentary canal, in the liver, spleen, kidney, urinary bladder, lungs, pleura, heart muscle, skin, and hair.

The contents of the cysts are numerous spore-like bodies, round, oval or spindle-like in shape, each consisting of a firm capsule which may be bivalve, and which contains protoplasm at first homogeneous but subsequently becoming transformed into sickle-shaped bodies endowed with active amœboid movement. These sickle-shaped embryos possess the power of penetrating epithelial cells, and, when they have thus obtained a local habitation, of growing and becoming nucleated.

Considerable importance has been attached to a knowledge of the development of Gregarinida from the fact that when psorosperms infect lepidoptera they may cause the death of their hosts, for it has been shown that they produce silk-worm disease.

It is only within the last few months, however, that M. Darier and Dr. Wickham in France, Mr. Bowlby and Mr. Jonathan Hutchinson, Jr., in this country, have pointed out the relationship which these organisms seem to bear to Paget's disease of the breast, and to some other forms of skin affection. In Paget's disease the superficial layer of the epithelium covering the nipple, is absent to a great extent, whilst the rete mucosum remains in patches, which are often vacuolated. The general appearance of the bodies in the tissues in this disease is shown in the drawing made by Mr. Jonathan Hutchinson, Jr., to illustrate Dr. O'Neill's report of this case. The "vacuoles" appear, by the light of recent observations, to be probably parasitic in their nature, since they are caused by psorosperms. If this hypothesis should prove correct, it will, of course, materially modify the treatment of the disease, for instead of extirpating it with the knife as the surgeon has hitherto done, it will be treated by the application of strong antiseptic solutions in the manner recommended by Dr. Wickham. The acceptance of this view will also necessitate a modification of the pathology of Paget's disease, and we shall have to agree with Mr. Bowlby, who believes that all changes in the breast are secondary to those occurring in the nipple, and are not in any way the cause of the so-called eczema. It is at present a vexed question whether the cancerous growths in these cases are or are not directly due to any specific action on the part of the psorosperms, but before this point can be settled with any degree of certainty, it is necessary to be able to cultivate the organisms. Messrs. Ballance and Shattock have lately declared that their experiments in this direction had been unsuccessful, whilst Dr. Delépine and Mr. D'Arcy Power announced that their work had yielded evidence of a positive result, though it was as yet too early to speak with any degree of certainty. The question, however, is one of great importance, and we shall watch with interest such further results as may be obtained.—*Brit. Med. Jour.*

MEDICAL CHEMISTRY.

METHYL-MERCAPTAN—C_6 H_4 S.

This substance gives to the urine voided after eating asparagus its peculiar odor,—as was recently ascertained by Nencki, after a futile attempt to determine the cause of this peculiar odor had been made before by Hilger. Nencki distilled the asparagus-urine, previously acidulated with oxalic acid, over a sand-bath, whereby the escaping gases were passed into a wash-bottle containing a 3% solution of mercury cyanide, which *retained* the methyl-mercaptan. According to Löw, the mother-substance of methyl-mercaptan in the shoots of asparagus is, in all probability, an organic sulphur combination of simple structure, accompanying the asparagin.—*Merck's Bull.*

MODIFICATION OF FEREIRA'S TEST FOR COCAINE.

M. G. Patein contributes the following to the *Répertoire de Pharmacie:* Into a watch-glass pour a small amount of the liquid that is to be examined, and evaporate carefully over a water-bath or lamp to dryness. Treat the dry residue with a few drops of alcohol of 95°, and add a small bit of caustic potash. If cocaine be present, on agitating the glass a powerful odor of benzoic ether will at once be perceived. This odor is very intense, and persists a long time. So delicate and certain is the test that the presence of a small fraction of a milligram of cocaine or its salts is easily determined.—*Nat. Drug.*

NEWS AND MISCELLANY.

PEPPER AND MUSTARD IN BRIGHT'S DISEASE.

An exchange says that a Russian physician has proved, by direct experiment, that pepper and mustard given to patients with Bright's disease, increase the excretion of albumen in all forms of the disease.

NEW YORK MEDICAL EXAMINER.

Dr. G. W. Wells, of New York, is to issue a journal known as the *New York Medical Examiner*. It will be devoted to medical matters connected with life, accident, and marine insurance, the army, navy, police, fire department, pension service, railways, etc. From its announcement it should prove a success.

MEDICAL SCHOOLS IN CINCINNATI.

Dr. James T. Whittaker says the medical schools of Cincinnati represent every freak, fraud, and frenzy of which the human mind is capable. There is a Hospital for every race, for every creed, for every sex, for every age, and at present rates there will soon be one for every disease and every doctor, as founders of hospitals and medical schools, are physicians, preachers, fashionable ladies, and men who have made fortunes by questionable means, as vending patent medicines.

HOW THEY MANAGE THE NEW-BORN CHILD IN TURKEY.

Dr. Weller, of Pottstown, Pa., in the Medical and Surgical Reporter, Nov., 1888 (old but good), is incited by Dr. Ay's article to offer a few suggestions as to the "management of the new-born child," while I, by Dr. Weller, am incited to note a few things in regard to the subject at the head of this article.

Dr. W. thinks "improvement has been made in everything else except in the custom of dressing babies." I think could he make a comparison of the customs of this land with those of the west, he would admit that there had been some "improvement" even in that. With your permission we will attend a cases of confinement, not as attending obstetricians (as that is seldom permitted), but as guests! On entering the house we find it pretty well filled with females, relatives and neighbors—especially if the labor has been somewhat prolonged. The patient, we will say, is a woman (?) of some fourteen summers, and has been married a year or less, and this is her first experience. Up to the hour of labor she could have been seen strutting around, as proud of her protruding abdomen as a Chicago alderman; for the finger of scorn is usually pointed at the childless woman whosever fault it may be. She, the weaker vessel, is always blamed until proof positive is presented that the other gender is the one to blame. But we came to see the baby, not the mother, who by this time is not half so anxious to be a mother as she was a day or two ago; and she may be heard declaring in a loud voice that she is going to die, and that she will never again, no, never, have another baby!

While we are waiting for the coming stranger, let us take a look at how they are treating the soon-to-be mother. Up in the far end of the one-roomed house we hear the groaning, and, as our eyes become used to the light, we see two women sitting on the floor; between them is a third one, whose arms are around the necks of the other two, while they have one arm thrown around her back, and the other supporting her in a half-sitting position. On looking closer we see the middle one is over a copper dish, that they use for a wash tub. If our eyes have not already seen, our ears cannot have helped hearing the voice of a fourth person—the midwife—who is sitting in the rear, her head planted into the region of the sarcum, her hands pulling away at some unseen object, and constantly calling upon the mother, "*dee! dee!*"—which if put into our language might be, "bear down! bear down!"

At last through a sufficient amount of pulling and bearing down, a faint wail indicates a new life, and a general stampede is made by all present, great and small, to get a peep at the new-comer, when from every quarter the cry goes up: "What is it"? "what is it?" If it should be a girl, you will notice a hushing up of all concerned, until some old mother in Israel present will remark: "It is the gift of God. Praise His name; all is well. If it should be a boy, light to your eyes! light to your eyes! May the blessing of God rest upon you," etc., will be the cry. The midwife is now lustily calling for a string and a shears. Now, my dear antiseptic brother, do not be too much shocked at the string and shears, they hunt up and bring to perform the operation. The string may be broken off from a ball of stuff rolling around under foot, while the shears—forgive me—is a pair that might have been used for

shearing sheep in the fourth century! Nevertheless they are sufficient. The tie is made, and the cord sawed off close to the abdomen, while a dozen voices sing out: "Take care, do not cut off the penis,"—a thing which sometimes happens.

The child is at last disconnected, and is taken from the hands of the midwife, who on no account will let go her hold on the cord until the after-birth is delivered, lest it might digress from its natural path, and find its way into her stomach and thereby smother her.

We follow the child. A rag is set on fire, and the still bleeding stump of the cord is well scorched, to prevent all further oozing of blood. He is then taken and rubbed all over with salt, wrapped up in some old rags, and fed with some flour and molasses. The latter is given to move his bowels, as the milk of the mother for the first day or two is not fit for him. The next day he is washed and dressed; his clothing is more suited to a two-year old than for a new-born infant. In this they might please Dr. W.; no bands, not even any dressing over the burned stump; no diapers, in place of which a large cloth, any color, is covered over with dry earth and placed under him next to the flesh; his clothes are then drawn down, scarcely coming to his feet. He is now laid on a large square wrapping cloth, which is folded up over his feet, and brought over so that but two corners are left out; they are carried around him two or three times, folding in arms and legs, when the whole is knotted up tightly, some taking extra pains to see that it is well tightened. This is to develop the muscles well, so that he may be strong (?). The head is tied up, a band going around it, and another under the chin—cap and bands each of a different color. He is now ready to be passed around, handed to any and all who come in to congratulate the new mother. If he gives a whimper they at once extract their lacteal resources, and apply them to the mouth of the infant, who in this way may partake from half a dozen or more breasts in the course of a day. They all think they are doing God-service in thus contributing to the support of the growing youth. You cannot imagine how convenient the child is for handling tied up in the way mentioned.

We will not change his clothing, nor wash him again for ten days; only the earth may be changed once or twice a day. After his second wash—at the expiration of ten days—he is not again washed for one month, after which he has a rest from water and all its bad consequences for six months. Then, if he is a good, healthy boy, he is allowed to go to the bath with his mother every fifteen days. In the meantime a great many of them become eczematous from head to foot. Their ears almost always become ulcerated before they are two months old, some of them lasting for years, and the ear becoming useless. Very few heads but what are bald ere they are ten years of age!

When he is a day or two old, he must try his new cradle—a primitive structure with a frame-work over it, to hold a blanket, which is thrown over it. He is always placed upon his back, tied in so snugly that no part of him can move except the head, which keeps up a constant motion with every move of the rocker. When he is put to bed, a small reed tube is applied to the water-course, and carries the fluid outside into a small tin pail suspended on a peg for the purpose, which is emptied as occasion requires.

Now I would ask Dr. Weller what he thinks of eastern customs.

The other day I was asked to see my hostler's wife, who was supposed to be in labor. I did not rush out at once, but stepped up stairs and put on my coat, and went to the house, just outside the yard. I went in, and found her on the floor groaning, with not a soul near her except a three-year-old child crying over her. As soon as she saw me she cried out, "Oh, I am dead!" I asked her what the trouble was. "I never had it happen so before." "What is it?" "Why, it has come." And sure enough it had come! So I went back to the house to get my pocket-case to separate the little fellow from his attachments. By that time the mother of the woman had come to lend a helping hand. What would our dear ladies at home think of such labors? And Dr. W., what would you do with babies coming on such an express train as that? And yet I agree most heartily with every word he says. I only wish there were more like him to urge on the reform. Here in Turkey we have but a few lying-in-cases—only those the old midwives cannot do anything with. Whenever I am called, I insist on the patient going to bed, and deliver them "a la Frank," and see that the baby is attended to "a la Frank" also.

At some future time I will write you something about the mothers.—*Trained Nur.*

Clinical Lectures.

TRACHEOTOMY IN AN ADULT — FRACTURE OF THE SKULL—GUNSHOT WOUND OF THE CHEST—STRANGULATED INDIRECT INGUINAL HERNIA.

BY THOMAS H. MANLEY, M. D.,
VISITING SURGEON TO THE HARLEM HOSPITAL, NEW YORK.

TRACHEOTOMY IN AN ADULT.

Gentlemen :—The first case that I will exhibit this afternoon is one which illustrates the difficulties often attendant upon the performance of tracheotomy in an adult. In this instance, as you see, the patient deliberately cut his throat with a knife, the instrument passing horizontally across the neck immediately above the upper margin of the larynx, dividing the epiglottis and penetrating as far posteriorly as the anterior wall of the œsophagus. When he was brought to the hospital he had lost a considerable quantity of blood and was breathing with more or less difficulty through the opening made in the neck by the knife.

As there was marked dyspœa npresent, with evident congestion and œdema of the sub-mucus tissues of the glottis that threatened suffocation, it was found necessary to perform a prophylactic tracheotomy, but owing to the severance of the muscles which connect the thyroid bone with the larynx, there was a wide separation of the tissues, resulting in the collapse of the trachea and elevation of the hyoid bone through want of action of its antagonists in the opposite direction downwards. Hence, the difficulties that lay in the way of exposing the trachea and inserting a tube.

It is well to remember that normally in a child up to the fourth or fifth year, the rima glottidis is on a level with the intervertebral disc of the third and fourth cervical vertebræ, but after adult age is reached it has sunk to a level with the fifth intervertebral cartilage, so that while in early childhood the aperture of the glottis may be readily defined with the index finger passed through the angle of the mouth, after adult age, this is impossible, as it lies not only further down, but further forward, and is accordingly difficult to reach. The trachea is normally deeper in the adult than in the child. From the inner surface of the intervertebral notch the tracheal rings are separated for a distance of fully an inch and a-half, which space is occupied by the thyroid body, muscular and cellular tissues and the integument, all of which are exceedingly vascular.

In the case of this patient before it was possible to expose the trachea, it was found necessary to forcibly lift it out of the thorax into which it had collapsed. Besides, as a result of the incision through the tissues of the neck, there was an extensive infiltrate through all the parts, both external to and beneath the deep cervical fascia, so that the distance from the surface of the integument to the trachea was nearly three inches.

Under these circumstances, there are many difficulties in the way of performing a tracheotomy, which, if you are prepared to meet, might cause you no small amount of trouble. The first difficulties lay in the fact, that as we seldom or never tracheotomize except when the patient is suffering from stenosis of the larynx or air passages in some part of their course, the administration of an anæsthetic often becomes an impossibility as the inflamed condition of the mucus membrane of the air passages occasions such extreme sensitiveness that the inhalation of the anæsthetizing agent is attended with violent coughing spasms, and sometimes the arrest of breathing altogether. Accordingly, in this case, we will employ a method which may be described as the Reclus-Dawson plan of performing tracheotomy, that is, to cocainize the parts by the use, hypodermically, of a

one per cent. solution of the hydrochlorate of cocaine, using about a hundred drops of this solution both in superficial and deep injections, as laid down by Reclus in the use of this anæsthetic in surgical procedures. The next step in the operation is to make the trachea dry and free from blood, as recommended by Prof. Dawson, of Cincinnati. This is done by compressing all the bleeding parts by means of forcep pressure clamps, as each layer of tissue is exposed until the bare trachea is reached. Two great dangers are eliminated by this procedure, first of which is the danger of the escape of blood into the trachea, and the second is our ability to now dispense with a general anæsthetic.

Dr. Manley proceeded to perform the operation according to the plans here advised and no difficulty whatever was encountered in exposing the parts; during which time, the patient appeared to be perfectly free from pain or inconvenience. When the trachea was opened and the tube introduced the respirations were carried on with a marked freedom from oppression or distress.

FRACTURE OF THE SKULL.

The second patient is that of a boy, nine years old, who was brought to the hospital eight days ago suffering from a fracture of the skull sustained by falling from a height of forty feet into the back yard of the house in which he lived. When brought to the hospital by the ambulance surgeon he was in a state of most profound collapse. The integument was cool, the pulse irregular, slow and thready, and he breathed in a sort of spasmodic gasp. On entering the hospital he was placed in bed, hot applications made to the extremities, and after the lapse of some six hours, re-action gradually became established and consciousness returned. At this time I saw him and on examination found a well-marked depression of the skull in the tempero-parietal region just above the right ear anteriorly. Associated with this was an extensive infiltration of blood into the subconjunctival tissues of both eyes and a copious hæmorrhage from the nose, which latter had, however, largely ceased when he came under my observation. In other words, there were definite and positive indications of depression of the cranial bone at the seat of injury, besides fracture of the anterior fossa of the base of the skull. No paralysis had developed or convulsions of any sort, and apart from the general shock that he had suffered, his condition was fairly good. Now the question comes up, what line of treatment is proper to follow in conditions of this description; in children in whom, we have evidences of fracture of the cranial bones; but in which, there are no objective symptoms of extensive cerebral hæmorrhage or destruction of cerebral tissue? I have been taught from practical experience to follow an extremely conservative course, in such cases and one, from which I have made it a rule to never deviate; that is, to leave alone, unless indications for interference are clear. I have found, in operating on the crania of children, that the cranial bones and peri-cranial tissues are extremely vascular, and despite any precaution that you may take to prevent it, considerable blood is lost before the membranes of the brain are exposed. A condition usually, very badly borne, by a growing child and one apt to result in very serious consequences. Furthermore, the meninges of the brain and the cerebral tissues of a child are very susceptible to the irritating action of atmospheric influences, antiseptic solutions, or digital manipulation. In the majority of cases of children, where I had found it necessary, to open the dura-mater, for fractures or suspected fractures of the skull, traumatic meningitis developed, and in spite of every effort that could be brought to avert it, it generally ended fatally. It is for this reason I have always deemed it safer to pursue the conservative course in traumatisms of the skull in young children.

The ecchymosis beneath the serous tissues of the eyeball has already, nearly undergone complete absorption and the boy's general condition is excellent.

GUNSHOT WOUND OF THE CHEST.

The third patient that I will show you is a young man of powerful physique, who sustained during a quarrel, a gunshot wound of the chest. The ball penetrated the right pleural cavity an inch and a half to the right of, and about one inch below the nipple of the right breast, taking a downward and backward direction.

After admission to the hospital, the patient complained of a persistent pain in the abdomen and an extreme sensitive or moderate pressure over all its areas from the pubic bones up on either side.

Physical examination revealed no positive evidences of effusion into the right pleural cavity, but on the third day of his admission the pain gradually spread from the umbilicus upward, and it was then evident that he was suffering from a pleurisy, probably induced by the escape of blood from the lung into

the pleural cavity, which excited a hypersecretion of the serous membrane of the pleura. Now, septic infection had developed, and this was a positive impossibility to prevent in cases of penetrating wounds of the lung, whether done by an instrument or by a bullet, no matter how you may treat the external wound.

Accordingly, the indications for treatment are generally clear. If we are to give our patient the best chance of recovery, we should make a free incision through the walls of the thorax, either over the point of entrance of the bullet, or at its most dependent part, and remove whatever purulent or extravasated accumulations, or other matters that may have been carried in by the missile. Then, thoroughly irrigate and drain the pleural cavity, and apply the dressings so that future drainage and irrigation can be kept up until a cure has been brought about.

The operator then directed the patient to be turned on his left side, and after the integument had been carefully cleansed and rendered thoroughly aseptic, an incision was made into the nineth intercostal space, the scalpel taking a downward and forward direction. After the pleura was exposed, it was divided, and with a sharp rongeur, the greater portion of the shaft of the nineth rib for a distance of about a half an inch immediately over the incision, was exsected. This gave vent to a very large discharge of a sero-sanguinilant fluid, mixed with flocculi of lymph, tinged a deep-yellow bile color, thereby clearly indicating the fact that the bullet must have taken a downward direction, passing from the diaphragm into the liver, and possibly into the peritoneal cavity; otherwise, it would be difficult, to account for this backward flow of the bile through the diaphragm into the pleural cavity. Under these circumstances, the prognosis would be very bad, because, without doubt, the peritoneal cavity had been opened by the missile and septic infection had already commenced. The beneficial effects of the operation would be then local in its action and would be confined to the function of respiration alone. If the bullet had not, however, passed through the liver but was encapsulated and if a purulent formation should develop, his chances of recovery were best secured through the backward vent for this accumulation up through the diaphragm and out through the intercostal opening.

Two drainage tubes were then introduced through the opening made by the rongeur in the rib, and antiseptic dressing applied. The patient rallied well from the ether and expressed himself greatly relieved when consciousness had returned.

STRANGULATED INDIRECT INGUINAL HERNIA.

The next patient presents a few features of considerable interest in his history. He is a colored man, 40 years of age, and has suffered from hernia as long as he can remember, though it has not been of very large size. He has been able to get along very comfortably by the use of a truss until about two years ago, when he developed a strangulation of the intestine which he was not able to restore as formerly. A physician was called in who, by the use of topical applications and moderate taxis, succeeded in replacing the bowel. From that time on he wore a truss continuously until about two days previous to his admission to the Hospital when one morning he neglected to put it on, on going to work. While engaged in lifting a heavy load he felt something give way in the neighborhood of his groins which at once attracted his attention. He noticed a very large lump occupying that part of the body, and this was soon followed by extreme pain in the back, persistent vomiting and great weakness. He tried in vain to reduce it working at it for over an hour until at last a physician was sent for.

When the patient was brought to the Hospital, the house-surgeon employed as much taxis as he considered within the limits of safety to the patient, giving him a hypodermic injection of morphia, applying ice-bags over the protrusion, elevating the pelvis, and making continuous pressure over the hernia, but all to no purpose. Now, the strange feature of the case came up, and it was not peculiar to this case alone; for I have seen it occur four times, at this Hospital within the last six years; and that was, notwithstanding all that the house-surgeon could do to reduce the hernia, when the patient went to sleep, the protrusion gradually returned to the peritoneal cavity of its own accord. So when the doctor was making his evening rounds of the ward, when the patient awoke from his sleep, he found that the hernial protrusion had spontaneously disappeared.

The operation which I shall now undertake is not done with the view of curing the hernia, for no operation that has been yet devised can bring about that result, but for the purpose of placing the hernia in a posi-

tion in which it can be comfortably controlled by a properly adjusted truss. My experience has led me to perform no hernial operations, except in uncontrollable, painful and strangulated cases where surgical intervention is justified in order that it may be more easily and safely controlled in the future, by means of pressure. With regard to the form of operation I shall employ in this case, I would say, that there is no particular variety of operation that is applicable to all kinds of hernia. There were some operations in which a division of the canal, liberation and enucleation of the sac were performed, but then these were hernias which had no sac, as, for instance, the congenital variety, or a hernia which bursts through the peritoneum and comes down through the divided slit without any peritoneal investments. In other cases, the inguinal canal could not be divided because there was no canal in such cases; as for instance in a case of direct inguinal hernia where the protrusion carried the conjoined tendon down with it instead of the intercolumnar fascia. In those large, old protrusions, in which by the size of the hernia and the gradual distending force of its walls, the inguinal rings approximate and no inguinal canal is found to exist.

As for doing the open method or the closed one, in this case I shall be wholly guided by the circumstances as I shall find them. If the case is a recent one of strangulation and there were extensive accumulation of foul, fœtial secretions and danger of infection of the peritoneum, then I would by all means, treat the patient by the open plan, as it affords freer and fuller exit to the septic material.

But, if on the other hand, the process consisted in replacing the protrusion, closing in the inguinal rings and affecting a temporary cure, with such restoration of the parts as would render the ultimate wearing of a truss a comfortable procedure, I would then sew up the primary incision from end to end, taking care only to secure a homologeous approximation of the different coverings of the hernia from the serous membrane to the integument. I should employ no drainage except a small twist of cat-gut at each end of the wound.

The patient having been placed under the influence of ether and the parts shaved and cleansed, first with soap and water and then with a bichloride solution of 1–2000, the operation was commenced by making a free incision over the seat of the hernia, beginning over the center of the external ring and bringing it down to within about an inch of the base of the scrotum. The parts were then freely and rapidly divided and the sac exposed. This was then opened after it had been completely freed from the elements of the cord and it was found to contain a large serous effusion, about six inches of the small intestine, the whole of the appendix vermiformis, and but a slight fringe of omentum. In the large majority of cases of inguinal hernia it is important to bear in mind this fact that the segment of intestine which comes down will be almost invariably found to be that part of the ileum which terminates in the caput coli. After the intestine had been returned to its proper position in the abdominal cavity the parts were then freely irrigated with a 1–10,000 solution of bichloride of mercury, the sac was put upon a stretch, twisted at its neck and ligated high up with a strong silk ligature. It was then divided below the point of ligation and the divided neck of the sac was permitted to retract into the abdominal cavity. The widely separated pillars of the external rings were next drawn together by two strong sutures, and the parts below having been thoroughly irrigated, were approximated layer by layer; the cutaneous incision sewed up from end to end, with no drainage, except at the scrotal end where a small drainage tube was inserted. Iodoform and biclhoride gauze dressings were now applied over the wound and the patient was returned to the ward.

TREATMENT OF FLATULENCE.

Flatulence is a trouble that sometimes defies medical treatment. A French journal recommends the following:

℞

Naphthol.....f3j.
Carbonate of magnesium.....3j.
Powdered charcoal.....3j.
Essence of peppermint.....gtt. ij.

This is to be divided into fifteen powders, and one taken at the beginning of each meal.

When the flatulence is accompanied by constipation the following may be used:

℞

Magnesium sulphate.....3j.
Flowers of sulphur.....3j.

To be made into fifteen powders, one of which is to be taken at each meal.

When diarrhœa accompanies the flatulency:

℞

Bicarbonate of sodium.....grs. xxx.
Prepared chalk.....grs. xv.
Powdered nux vomica.....grs. iij.

May be made into ten powders, one of which is given with each meal.

—*Pharmaceutical Record.*

TRAUMATIC MENINGITIS; FRIEDERICHS ATAXIA IN A CHILD.

BY DR. J. MADISON TAYLOR,

DELIVERED AT THE CHILDREN'S HOSPITAL, PHILADELPHIA.

Gentlemen:—I have asked the mother of this little child to come and show it to you. They came in my office just as I was leaving. It seemed to me of interest that you should see a well marked case of recovery after a pretty bad traumatic meningitis. This child applied to me to-day for some triviality, but in the main, as you see, it is very well and strong, thoroughly well grown and nourished; in fact, it is a singularly muscular girl. The history of her trouble is as follows: When seven weeks old the mother had left her in the house with an older child, in her absence. When she came back, shortly thereafter, the little one had evidently been shaken or cuffed by the older child, because she was found in the very act of doing so. What injury the little one received it is impossible to know. She certainly was very much knocked about, the mother thinks thrown several times against the floor. The child who did this had notably a very bad temper, and the injury might have been even greater than could be known. Certainly the back of this one's head was very much bruised and battered, and she was completely black in the face, shocked, and reduced to a condition of almost palsy. From that time until several months old she was in a miserable sickly condition, ailing all the time, and upon the slightest provocation rejected all food unchanged. The mother nursed her, hence she got the best of nourishment; but, as I say, her condition was wretched until about fourteen months of age. When I first saw the case it had evidently a very high fever, and was exceedingly painful to handle. There was no part which could be touched without making it cry out, and hence after a hasty survey I diagnosed rheumatism; but upon my next visit I was enabled to make a more careful study and also learned of this injury described, and then found other evidence that it was manifestly a meningitis. Later the pupils became mere pin points, the limbs in constant painful contracture, the abdomen cupped and contracted, the head thrown back in a condition of opisthotonos, the eyes were kept closed, nothing was held on the stomach, not even water, and for ten days she did not sleep nor retain any food. All this while the bowels were obstinately constipated. The temperature I have no record of, but it was extremely high. The pulse slow and hard. The case lasted for about a month and got entirely well. The value of this is not so much simply as a case of typical, traumatic meningitis, as that it should have gotten so well; nor was the treatment used anything especially suggestive,—counter-irritation along the spine and the nape of the neck, hot mustard water, quieting medicines and carefully pre-digested food. But now the real interest centres in what effects are left from a case of this kind, and from such opportunities as these, much may be learned. One rather remarkable thing is that there seems to be no evidence of any malnutrition or lowered health in this child now. The digestion is excellent, general vigor good, and as I remarked before, the muscular development is singularly fine. The child is exceedingly intelligent, a little bit over shrewd perhaps, and with a trifling tendency to be cunning, but one very noticeable feature about it is an easily aroused and violent temper. It is interesting to consider how many subsequent mental peculiarities may be traced to some early brain injury of this or other kinds. I have in my mind the very noticeable instance of a daughter of a prominent literary man, who was herself remarkably clever. She and her sister had, you might say, a continental reputation for cleverness. This gentleman had been diplomat at a foreign court, and there both these daughters shone in various ways. The girl, when I knew her, was about 20 years of age, and insane. There was history of a very fair amount of intellectuality; she had written some clever poems, and was exceedingly interesting personally and in conversation. Nevertheless the mental obliquity was unquestioned, and was regarded by those who had her under advisement as probably most serious. From an accidental circumstance she died suddenly, and it was because of this that I was enabled to make an autopsy. Barring some disturbance of her uterine appendages, there was little amiss except evidences of a slight meningeal thickening, symmetrical in character, which was probably the result of a very severe attack of scarlatina as a child. There were then, I believe, as nearly as the parents could recollect, symptoms which might have been attributed to a meningitis. Afterward the temper of this girl had been notably erratic until it

culminated, as I said, in a condition of mania most distressing.

Now the lesson from these cases is that while of course every effort must be made with absorbents and such like remedies to try and relieve adhesions and thickenings, if indeed that be possible, our chief hope is that something in the way of treatment may be had from thorough and careful mental training so soon as a condition of this kind is recognized.

The next case I have to show you is one of considerable rarity although the total cases reported amount to something over two hundred. This little boy of nine years of age applied first at the Dispensary some weeks before I saw him for an irregularity in his movements which was pronounced chorea. Indeed he was treated systematically for chorea and seemed to improve under it. When I first saw him there were certainly choreic movements in the hands but they were so slow and so irregular that they had not even the irregular regularity which chorea has; and in causing him to walk to and fro on the floor, his gate was so manifestly bad that the possibility of his having some motor ataxia suggested itself, and upon examining him I found the knee jerks entirely gone. There were other symptoms which I shall detail presently which made me think the case one of locomotor ataxia, an exceedingly rare disease in childhood. In fact it is pretty nearly determined, certainly most observers now admit, that it is scarcely possible for a case of true locomotor ataxia, or sclerosis of the posterior columns of the cord, to exist in childhood at all. Of the reported cases, while some few seem to have the regular symptoms of locomotor ataxia, yet are the notes not sufficiently clear to make us certain that they were not what I think this case to be, namely, one of F. Friederich's ataxia. Now I will rapidly go over some of the leading features of this boy's case. I have looked pretty thoroughly into his history which is about as follows: The family records are thoroughly free, so far as I can make out, from any evidence of similar disease. The immediate family consists of seven children, of which he is the fourth, all robust and hearty, of Alsace parentage although born in this country. Until the age of eight years this boy really had no grave illness; he was always strong and well. In June last, however, at which time the mother thinks he was about the plumpest and best favored of her children, the various phenomena which I will detail, commenced to appear. Before that, however, it is well to mention some evidence of there having been ataxic symptoms. For at least a year the child fell too readily while at play; about his nose and face are numerous scars from contusions he then received. In June last there is a rather vague history of a fright caused by some boys who either chased him or did him some bodily harm, actual or possible. There is also some suspicion on the mother's part that he received a severe blow or kick on the end of his spine, but this is not definitely known. Before June, then, there was little or nothing to call attention to him except that he stumbled about irregularly. At that time, however, the clumsiness greatly increased, and was shown chiefly in the hands; he dropped dishes and other things from them. He could scarcely feed himself so great was this disturbance. He was taken to a physician and quite naturally, it would seem, the disorder was pronounced to be chorea, and treated accordingly. In a few weeks this passed entirely away, and also there were other notable phenomena observed, such as the loss of whiteness and gloss to the skin which became muddy and yellowish, the muscles fell away from their customary plumpness, and even now, as you see, are flabby although fairly well developed. There was nothing particularly noticed about his speech which, is observed to be slow and scanning, but his mother assures me that since his earliest capacity for speech he has always spoken slowly and hesitatingly. Also, as you notice, the saliva has a tendency to dripple from his mouth. This is not new nor particularly well marked. Upon examination you will note he is a fairly grown lad, with well nourished body and of good color. His expression is dull, the mouth is held habitually open, and the slight salivary leaking can be seen at the corners of his mouth. His attitude is not alert, the head is thrown forward, and I am told he usually looks upon the ground as he walks, showing clearly a degree of uncertainty in his movements which is characteristic. The skin, is also of a greasy yellow appearance, and upon touch you notice that it is very flabby and loosely attached to the muscles. Examining the spine as we now do there is no irregularity noticed nor is there any tenderness upon pretty vigorous thumping of his back. Examing the coccygeal region there is nothing noticed in the way of an old injury, nor does he complain on pressure or blows there. His heart is distinctly flabby with feeble sounds, and a rough systolic murmur is heard. The pulse is quite rapid and irregular. Now we come to ex-

amine the most noticeable feature, namely, his lack of power to stand. Standing thus before you the poise is quite unsteady. If I bid him bring his feet together, even with his eyes open, there is a notable sway back and forth. When I tell him to shut his eyes at once you observe the sudden reeling forward and to the right. The measurement of this sway is about two inches in each direction. This, in examining ataxics, is called the station, and we describe it as an antero-dextro sway of about two inches in each direction. When he walks you observe that he throws his heel down first and quickly follows it by the ball of the foot, as if he wanted to get as broad a base as possible on which to stand. This is true of ataxics always and gives them the characteristic gait. The foot is thrown forward suddenly and with a tendency to spread itself out as far as possible and thus widen the base. On turning quickly, the toe of one foot almost always touches or strikes the heel of the opposite foot; so much so that if I make him do this rapidly two or three times it will actually cause him to fall. Now upon examination of his legs still further we find the knee jerk entirely gone, the ankle jerk entirely gone, and all the tendon reflexes about the lower limbs have disappeared either directly or upon reinforcement. It is just as well here for me to explain this phenomenon of reinforcement. When the tendon is struck from which you expect to get areflex, it frequently happens that little or no result is seen, but when you can get the patient coincidently to this to make some decisive muscular act, as the closing of the hand quickly, or even the winking of the two eyes quickly, the motor wave, as we may call it, is increased until the tendon jerk is also enhanced and made more noticeable. Here you see the tendon jerk is utterly gone. Upon examining the arms the biceps tendon is made easily to re-act upon the simple blow, and really to act exaggeratedly upon reinforcement by clenching the other hand; so that although there is distinctly some ataxia in the arms, still the tendon reflexes are present, although the accuracy of the movements of the hand are notably lessened. For instance, you see with his eyes closed if I tell him to touch the tip of his nose quickly with the front finger of either hand, he misses the point by an inch or two each time. Also, even with his eyes open, upon buttoning his coat he fumbles clumsily. There is one other reflex easily noticed in this child, and that is the jaw jerk, rather an important one because we may have a reflex present here and yet those from the lower limbs and upper limbs quite gone. Now then, as to the question of what is called static ataxia, that is the power to hold any part of his body steady under the impulse of the will. For instance, I tell this boy to hold his two hands out in front of him spreading forth the fingers, and you see a decidedly irregular movement in them in strong contrast to that of a healthy boy who could quite easily do this. Upon grasping objects, however, which has also to do with this symptom, there appears to be no special defect.

Again, the muscles of the face twitch irregularly but slowly, showing that the balance of muscular activity is well below par throughout the entire body. Doubtless this feature, irregularity in the movements of the muscles of the face, helped to make the diagnosis of chorea earlier in his history. There is no definite tremor, although tremor is a common feature of this disease, nor is there any spasm, nor palsy, nor contracture. There is also an entire absence of pain now, or at any time. Electrically there is no particular change in his muscles, nor, indeed, is there any characteristic electrical symptoms recorded in this disease. My friend, Dr. Oliver, who has taken great interest in examining the cases of this malady for Dr. Griffiths in the very elaborate and complete study which he made of it, has also kindly given this boy a thorough overhauling, the conclusions of which are as follows: The central vision for both form and color is normal in each eye. The power and range of accommodation are, however, lessened. The visual fluids are very slightly contracted, the pupils are about the same size, the irides equally and freely mobile to light stimulus and convergence, but quite sluggish to accommodative efforts. There are no coarse changes in the intraocular media or fundus. You see we have here just the reverse symptoms from those of the Argyl Robertson pupil, which should re-act less well for light than for accommodative efforts. In short, in this disease there is a much more general disturbance of the muscular activities than there is in the true locomotor ataxia.

Now, of course, in a clinic of this kind it is always interesting to say something as to treatment. I wish it were possible to give any hope that treatment of any kind, shape or degree could be of value here. Unfortunately, since in none of the reported cases has there been any definite improvement except spasmodically and in the way of nutritional gain, yet there has been nothing

found in any way to limit the progress of the disease or to regain lost ground. Such cases usually live a reasonable lifetime in varying degrees of helplessness, but little may be hoped from any line of treatment except such as is directed to the general health.

Very rarely does this disease progress rapidly but not the less surely, and while it is quite common for its victims to die of other causes than it, nevertheless barring any other reason, of this they will infallibly die soon or late. It is quite possible, however, to prolong the existence of these victims, and inasmuch as we are seemingly on the track of new and improved methods of treatment for true locomotor ataxia, so may some of these help us in this trouble. The treatment by suspension, of which so much was hoped, is still pursued in many special hospitals, and my own experience with it has been many times encouraging. Certainly I have seen certain features of locomotor ataxia obviously helped by this.

COMMUNICATIONS.

THE RELATION OF LACERATION OF THE CERVIX TO MALIGNANT DISEASE AND ITS TREATMENT.

BY WILLIAM E. ASHTON, M. D.,
GYNÆCOLOGIST TO THE PHILADELPHIA HOSPITAL.

We will first consider the condition of the neck of the uterus as to the presence of lacerations in women who are suffering with cancer. The fact must not be lost sight of that the vast majority of these women consult the surgeon at a time when their disease is far advanced and when it is impossible to determine whether or not a laceration be present. Therefore we must depend upon the child-bearing history of our patients, for, if a woman has borne children, it is fair to presume that her cervix has been the seat of a more or less extensive traumatism as it is exceedingly rare to find a parous woman with a virgin neck to her uterus.

During a period of eleven years 63 women with cancer, presented themselves at the clinic for diseases of women in the Jefferson Medical College Hospital. The histories of 5 of these patients were incomplete, there being no notes recorded as to child-bearing. Therefore, in considering these statistics, we must necessarily exclude these cases. The remaining 58 women all had borne children with one exception and the diagnosis in this case is far from certain, as no microscopic examination was made, the notes merely stating that she was sent to the ward and curetted.

The following table shows the age and the number of children borne by each woman of the 58 cases of cancer at the Jefferson Medical College Hospital:

Age at admission	23–30	30–40	40–50	50–60	60–67
No. of women for each period...	3	13	16	17	9
Total					58

No. of women...	1	12	5	9	4	5	9	2	2	4	2	1	2
No. of children each	0	1	2	3	4	5	6	7	8	9	10	11	13

Totals:

No. of women	58
No. of children	267

We find by studying this table that the average number of children borne by each woman to be 4.6. This is about the same average as is given by Emmet,[1] who in a report of 51 cases of cancer found in the aggregate 228 children, which gave an average for each woman of 4.47. Hoffmeier, quoted by Winckel, found the average number of deliveries to be 5.2.

The above table shows only 3 cases occurring prior to 30 years and 9 cases after 60 years. Therefore the period between 30 and 60 years would seem to be the most likely time for cancer of the uterus to develop.

Winckel[2] says: "The large majority of women with cancer are married. Of my patients only 1.7 per cent. were unmarried and two-thirds of these 1.7 per cent. had given birth to one or more children. Difficult labors, i. e., protracted or instrumental deliveries, are very frequently part of the history of these cases."

Winckel does not believe that pregnancy and labor alone can be looked upon as causes of cancer of the uterus but that "such a termination is apparent after numerous and difficult labors." In other words, labors which produce lacerations of the cervix are liable to cause cancer. Hoffmeirer, quoted by Winckel, found in 812 women suffering with cancer only 4.8 per cent who were nulliparæ. Gross[3] says: "Epithelioma of the uterus is most common in married females that have borne children. Goodell (Lessons in Gynæcology 1887) tells us that "of several hundred cases of cervical cancer brought to my attention, I have not met with a single

[1] Principles and Practices of Gynæcology p. 511.
[2] Winckel's Diseases of Women-Parvin, 1889.
[3] System of Surgery vol. ii. p. 891.

one in a virgin, and only two cases in undoubtedly sterile women. One of these two, however, although an exception to the rule, singularly confirmed it. The lady had a fibroid tumor which slowly enucleated itself. After she had suffered much pain and had lost blood for several weeks. I was called in and found the os uteri dilated to the size of a silver dollar. I easily wrenched the fibroid from its attachment, and delivered it, but with some difficulty, as it was larger than the os. A few months later cancer of the cervix set in, from which she died."

It is not necessary to bring forward other statistics showing that a large per cent. of women who have cancer of the uterus, have borne children and I will therefore not take up further space in stating facts about which there is a united professional opinion. The point, however, which I do desire to bring forward is that labor means more or less traumatism of the neck of the uterus. If this be true, and I firmly believe it to be so, we then have by knowing the child-bearing history of a woman suffering from cancer a strong presumptive evidence of the presence or absence of a laceration of the cervix uteri.

Having shown that it is the exception to meet with cancer of the uterus in a nulliparous woman we will consider the question, does a laceration of the cervix predispose to or cause malignant degeneration? The etiology of malignant growths is still unfortunately far from settled, as the various theories which have been from time to time advanced but too clearly prove. To my mind, however, the local inflammatory theory of Virchow is the one most fully sustained by clinical facts and by the concensus of professional opinion. I shall, therefore, in this paper, limit myself to the views of Virchow leaving out of the question the dyscrasia, nervous and spontaneous theories. Neither shall I refer to the view that abnormal growths are due to micro-organisms as this theory is at the present time far from being demonstrated. Furthermore even granting that pathogenic forms of protozoa are the cause of new formations it would in no wise weaken the view as to their local origin, for the micro-organisms would simply be the exciting, not the predisposing, cause. Formad[1] in discussing the various theories opposed to the views of Virchow, says, "as ingenious as they are, can hardly, at present, be regarded as theories, but must be called hypotheses, for so far, not a single tumor can be proven to have really developed from the causes promulgated." Virchow, quoted by Formad, says, "we also know that on mucus surfaces tumors occur for the most part in such places where there previously was a simple inflammatory disturbance; e. g., where the simple inflammatory catarrh precedes the growth of polyps and polyps may develop into cancer. In cancer of the stomach there is always seen a gradual transition of the catarrhal products to carcinomatous structure * * * *." We next come to certain regions of the body which, from their situation and the character of their function, are exposed to irritation and injuries; e. g., the stomach, sexual organs, bones, skin, and the different orifices. If we make an estimate of all malignant growths, we find that most occur at orifices and at the orifices which are exposed to the greatest injury, consequently those of the digestive and sexual apparatus are most affected." Dr. Woodward[1], U. S. A., and Samuel,[2] of Konigsburg, both agree with Virchow. The former states that, "The origin of the first growth was always to be looked for in local influences. Former injuries of one kind or another could be affirmed in a large number of cases to have preceded the development of the disease and, though frequently the patients had lost all recollection of the original harm, yet it is in this direction we ought to look rather than seek to explain away the real difficulty by invoking the aid of an imaginary cachexia." The latter takes even a stronger view as to the inflammatory theory and says, "The idea of excluding or even limiting the causative relation of chronic inflammation to neoplasm leads far astray from the right path." In epithelioma of the lip we have strong clinical evidence of the malignant growth being of a local inflammatory origin, as the history shows an irritation of long standing caused by the stem of a pipe and heated tobacco juice. Again, we frequently find cancer of the tongue associated with a rough and uneven condition of the teeth. Gall stones have frequently been shown to have proceeded cancerous disease of the gall-bladder; their presence having set up a catarrhal inflammation which eventually produced the new formation. Long continued pressure, cicatrices, the situation of an external injury and ulcers have all been fre-

[1] Etiology of Tumors, Trans. Path. Soc. Phil., vol. X, 1879–81, Formad.

[2] Ibid.

quently noted as the seat of malignant degeneration. Formad goes so far as to believe, "that all tumors are products of the inflammatory process, and that they should be considered as one of the terminations of inflammation."

The tissues of the neck of a uterus, which is the seat of a laceration, are in a precisely analogous condition as that of other parts of the body which undergo malignant degeneration the result of a chronic inflammation. Furthermore, the position and the function of the cervix renders it especially liable to the inflammatory process. In its relations with the vagina it points directly posterior and slightly toward the left side, resting, as it were, in the posterior cul-de-sac. It is not fixed in this postion but is moved upwards and downwards by the action of the diaphragm, while the abdominal pressure still further tends to keep it closely in apposition with the vaginal wall. Finally, the penis, during the act of sexual intercourse comes into direct contact with it. Therefore, this constant irritation to which the cervix is exposed as the necessary result of its position and mobility, tends decidedly, if it be the seat of a traumatism or of a so-called erosion, to produce a chronic inflammation which may become malignant. Another cause why the cervix is especially liable to an inflammatory process, is on account of its great glandular activity. Parvin[1], in speaking of the structure of the neck of the uterus, says. "The glands, which are so abundant in the cervix that Spiegelberg calls it a great glandular apparatus, are not tubular, like those of the corpus, but racemose." It is a well known fact that inflammation is more liable to occur in organs whose functions are active, and in the cervix we have a structure in which this condition of glandular activity is present, and in which, as the result of a traumatism, chronic inflammation occurs. That the glandular structure of the cervix does enter largely into the consideration in determining the causes of cancer of the uterus is clearly shown by Cushing[2], who says. "What are called erosions, ulcerations, etc., are various degrees of one process, which consists essentially in a new-formation of glandular tissue, on the surface of the vaginal portion, or in the cervical canal. The follicles and cysts are not usually enlargements of prëexisting ducts, but new-formed glands without ducts. In ectropium there is essentially the same process going on in the cervical canal, thus everting the lips. In a comparatively large number of cases, cancers of the cervix are preceded by this condition of gland formation, or, to state it otherwise, when inveterate not infrequently becomes cancerous." * * * * "Where there is a laceration, of course the cervical canal is more accessable, and more ready to take on a diseased action." In the discussion following the paper of Cushing just quoted from, Baker said, that he considered erosions a cause of cancer of the cervix, and that they were of importance even when slight. He advised immediate treatment to avoid the possibility of cancer developing. Strong also stated his belief in lacerations of the cervix being a cause of cancer of the uterus, and said that in the large number of cases of malignant disease of the cervix that he had seen at the Mass. General Hospital and the Free Hospital for Women, not one occurred except where pregnancy had existed.

Wyman[1] holds that "the part of the womb most frequently attached is the neck. It is probable that the injuries which this part receives in parturition, operate as a cause of the disease." Dunning[2] is of the opinion that "cancer of the uterus is frequently of local origin due to local irritation. Emmet's discovery of the pathological conditions due to lacerations of the cervix uteri has emphasized this fact. Few will go so far now as did many a few years ago, when it was the fashion to ascribe the vast majority of uterine diseases to lacerations of the cervix, yet the fact is well established that injury to the cervical tissue, if allowed to go unattended, will sometimes act as an aetiological factor in the production of epithelioma of the cervix." Spanton[3] in a paper on lacerations of the cervix uteri, states that "the importance of this condition has been made more manifest since recent observations have shown that it may be the precursor, if not actually the cause, of a large number of uterine ailments. Dr. Thomas enumerates no less than twelve of these as resulting from laceration of the cervix, and among them he places epithelioma. Other authors state the same thing, while some go so far as to declare that a large proportion of the cases of cancer we meet with in that region result from a damaged cervix." In the Annual of

[3]Brit. Med. Jour., April, 1887.

the Universal Medical Sciences for 1891, Spanton "records two cases where a malignant growth had developed from the site of a previously healed specific ulcer of the cervix."

Goodell[1] takes a strong position as to cancer of the cervix being caused by lacerations. After describing the various evils resulting from such traumatisms he says, "Further, I feel very sure that almost every epithelial cancer of the cervix starts from such a constantly chafed and fretted surface. For, in my experience, a cancer of even a movable womb, with a ragged notch on one side of the cervix apparently eaten down to the vaginal junction, is no uncommon event. Also, it is very rarely found in virgins or in sterile women." Again he says, "In the immense majority of cases of cancer of the cervix the disease starts from a laceration of the cervix—it is, therefore, almost always found in women who have borne children."

The opinions quoted in this paper together with my own statements, point, I believe, strongly to the probability of lacerations of the cervix being the predisposing cause of cancer of the uterus. If, therefore, this be true, our duty toward our patients is clearly defined and the only rational treatment of cancer of the cervix is prophylatic. It is not necessary to refer to the literature of the subject to throw light upon the fact that the results obtained in the radical treatment of cervical cancer are far from promising. Nay, it has even become a question in the minds of some of the profession whether we are justified in operating at all upon a uterus the seat of malignant degeneration, as statistics show such a large per cent. of recurrences. At any rate there is no denying the fact that cancer of the uterus dooms, yearly, a vast number of women to an early death. There is a strong tendency at the present day among gynæcologists to deprecate minor surgical operations upon the uterus on the grounds that they are unnecessary, and that the inflammatory conditions so frequently present in the pelvis render such interference dangerous, as being likely to light up an active pelvic or general peritonitis.[2] Although I am fully and sincerely in accord with those who believe in the necessity of excluding all possibility of ovarian or tubal disease prior to any manipulations upon the pelvic organs, yet my clinical experience has taught me that these minor operations do result in benefit in certain selected cases where we have clear and defined indications to guide us. This I believe to be especially true as to lacerations of the cervix, which should, in selected cases, be operated upon to guard against the possibility of cancer.

In considering the prophylactic treatment of cancer of the cervix we must first study the indications which call for surgical interference, and second, the methods of operating. We will classify the indications under two headings. First, those cases in which a laceration causes or is associated with a so-called erosion, and second, cases in which no erosion is present, but where the cervical tear produces subinvolution of the uterus. In the first class of cases we have present just such a condition as is most likely to result in a malignant new formation. In point of fact, the border line between an inveterate erosion and cancer is so illy defined that the microscope even fails to make a diagnosis. My rule in practice is to operate upon all lacerations of the cervix associated with erosion, if treatment fails, in a reasonable length of time, to effect a cure. In the second class of cases we have as the result of the chronic inflammation of the uterus, which is produced by the laceration, the catarrhal and other causes of cancer of the cervix. Therefore I also, under these circumstances, operate upon the traumatism to relieve the condition of subinvolution, which I believe is likely in some instances to degenerate into malignant disease. There is no doubt in my mind of the fact that the vast majority of lacerations of the cervix are physiological, and should be left alone, as they are followed by no evil results, but the point I do wish to emphasize is that, in cases such as I have just noted there is always danger of cancer resulting,and therefore they should be operated upon as a prophylatic measure. To further emphasize the necessity of operating upon a damaged cervix I shall quote from an article of Spanton in the *Brit. Med. Jour.*, April, 1887, in which, after speaking of a report of a case of laceration resulting in cancer, he says: "We have, therefore, in this instance a clear illustration of the possibility of cancerous growth supervening on simple hyperplasia of a damaged cervix, and once begun running a rapid malignant course; and this is the point to which I wish to draw attention. I am quite sure it is one which deserves careful consideration, and should lead us to remedy as speedily as possible every case of lacera-

[3] Noble—Trans. Obs. Soc., Phila., Aug. 1890.

tion or fissure of the cervix which gives rise to symptoms which do not yield to the ordinary local remedies."

Having given the indications which require surgical interference in lacerations of the cervix, I shall state my views as to what operations should be employed. A damaged cervix may be restored by either a trachelorrhaphy or an amputation. It is of the first importance to know which of these operations should be selected in a given case. Trachelorrhaphy should only be resorted to in tears which are not extensive and in cases in which the cervix is not hypertrophied to any great extent. Amputation of the neck of the uterus is indicated in stellar larcerations, in tears which are extensive or associated with loss of tissue and in cases where the cervix is hypertrophied. To attempt to do a trachelorrhaphy when an amputation is indicated would result in no possible good, either in removing existing morbid conditions or as a prophylactic measure against cancer. I have never seen any evil results arising from amputations of the cervix, either immediate or remote. [1] "Alloway, from a study of the influences of cervical amputations on future parturition, finds that it favors impregnation, makes labor more easy, less risk of injury to the cervix, and does not increase the chances of premature labor or abortion." In a case where I amputated the cervix for cancer in a woman in the fifth month of pregnancy, the labor at term was perfectly normal and resulted in no injury to the cervix. This has been my experience in a number of cases in which amputation was resorted to. Trachelorrhaphy clearly has its value and should be the operation selected in cases such as I have indicated, but I desire strongly to urge upon the profession the necessity of amputation when the existing conditions demand it.

The method used by some gynæcologists of taking a wedge-shaped piece out of the anterior and posterior lips and bringing them together, in cases of laceration associated with hypertrophy, I earnestly condemn as being both unscientific and useless. What earthly good can such an operation accomplish which leaves untouched at the site of the tear the cicatricial tissue which is the cause of all the trouble?

In amputating the cervix the technique of the operation is of great importance. The écrascur or galvano cautery should not be used, for after amputating the cervix with either of these instruments a large raw surface results which must heal slowly by granulation. This process of healing necessarily retards recovery and at the same time is liable to cause stenosis of the external os uteri.

The method I adopt in amputating the cervix is as follows: After the introduction of the speculum the anterior lip of the cervix is seized with a Volsella forceps, and with a pair of scissors the laceration is extended down on either side to the vaginal junction. The anterior and post lips are then amputated evenly with the vagina. This leaves a clean, raw surface which is covered over by stitching together the surrounding vaginal mucous membrane with silver wire, leaving the edges open directly over the os uteri and afterwards securing them with cat-gut sutures to the rim of the os. A continuous cat-gut suture is then introduced so that the os uteri is completely encircled at a distance of half an inch from the centre of its opening. This suture brings the flap of vaginal mucous membrane in close apposition with the cervical tissue. After the operation is completed the upper portion of the vagina should be tamponed with antiseptic gauze. This operation is a modification of the one devised by Sims in 1859, which consisted in simply covering the stump of the cervix by bringing together, with sutures, the surrounding vaginal mucous membrane. The objections to this operation as stated by Goodell are "cicatricial closure of the os and in the danger of secondary hæmorrhage, the mucus lid not making compression enough to close the open-mouthed vessels." To meet the first of these objections I follow the plan of Goodell and stitch the edges of mucous membrane which are directly over the os uteri to the border of the opening. The danger of secondary hæmorrhage I meet by the continuous circular suture of cat-gut; this I believe to be original with me. This suture not only lessens the danger of hæmorrhage but it also assists materially in securing union by first intention.

In conclusion I will sum up my views as follows:

1. I believe cancer of the uterus to be local and inflammatory in origin.

2. That lacerations are the cause, in almost every instance, of cancer of the cervix.

3. That the indication for operating upon a damaged cervix is pointed out by the failure of local treatment to effect a cure.

4. That trachelorrhaphy and amputation are the only surgical means to repair a damaged cervix.

[1] Annual Univ. Med. Sc., 1891.

5. That amputation should be resorted to in the majority of cases where an operation is indicated.

6. That the stump resulting from the amputation should be covered over by a flap of vaginal mucous membrane.

338 South 15th Street.

ON THE GREAT IMPORTANCE OF DRY TREATMENT IN CHRONIC OTITIS MEDIA.

BY LAURENCE TURNBULL, M. D.,

PHILADELPHIA.

In a paper which was read before the Virginia State Medical Society in the summer of 1890, the absolute necessity of the antiseptic treatment of this form of disease of the middle ear, was dwelt upon. Not only the agents employed, but above all, giving protection to the diseased cavity, by means of antiseptic gauze and other measures.

The great number of these chronic cases are found to depend upon some constitutional disease, either scrofulous, tuberculous or specific disease. In every instance the fluids employed to remove the diseased secretions, must be sterilized by boiling and should contain a small proportion of bichloride of mercury combined with iodium salt.

But no syringing should be done by the patient, only by the physician, and this chiefly for diagnostic purposes. It is necessary, to treat the cases with success, to find out by means of the speculum and mirror, the condition of the mucus membrane of the cavity and the membrana tympani so as to make the proper applications.

Should there be considerable secretion of pus, etc., the solution of the per oxide of hydrogen, 1 part, sterilized water, 3 parts should be employed. After each cleansing of the parts, and opening the eustachean tubes, the auditory canal is carefully wiped dry with absorbent cotton and the parts covered with finely powdered boracic acid and one-sixth per cent. of pure menthol camphor rubbed up together.

The inflation of the middle ear should always follow the cleansing process (preceded in every case by the patient's cleansing the nose,) and this inflation should be done with antiseptic air, by filtering it through bichloride of mercury cotton, placed in the centre of a bulb, and attached to the nose piece of Politzer's bag.

An adaptation of Politzer's idea in a primitive way has been made by one of my friends. He uses instead of the rubber bulb a moderate sized syringe, connecting with the nozzle a rubber tube. The operation is the same as with Politzer's bag, save that air is forced from the barrel of the syringe instead of from an elastic bag.

TWO CASES OF ACUTE PARENCHYMATOUS GLOSSITIS.

BY RAY W. GREENE, M. D.,

WORCESTER, MASS.

In looking up the literature of this subject I find so few cases reported that these two histories may incite some one else to report equally interesting cases.

On the evening of April 1, 1889, I was called to see a man of about 60 years of age, medium size, then of nervous temperament with previous history of occasional illnesses, but of only one serious sickness, viz., pneumonia some 8 years before. His occupation as Custom House Inspector at Boston had for 2 or 3 years become very arduous and the overwork was very apparent to his family and friends. To meet the demand of business this patient on his own account became a frequent user of hypnotics, which for years he had kept in the house for occasional use. Also from 1 to 2 f℥ of whiskey was taken at bed time for sleep. On the afternoon of the day mentioned, without any unusual exposure, the patient had quite a severe chill, vomited his dinner, felt very weak and his throat began to be sore. At 7 P. M. I found his pulse 120; temperature 103°; the fauces looked slightly congested, but the tonsils were not swollen nevertheless. I made provisional diagnosis of violent onset of tonsillitis, and ordered tincture aconite and tincture quinine during night, and Sedlitz powder in the morning. The following day the temperature and pulse were the same. He had passed a very restless night, although good sized doses of hypnotics had been given. In the afternoon the tonsils were red, but not swollen much, while the tongue was evidently quite enlarged so as to interfere with talking and swallowing. The patient was very nervous. I staid with him part of the night, producing some sleep by the use of morphine injected under the skin. On the third day he presented a most pitiable picture. The tongue was enlarged so as to nearly fill the mouth, and protruded half an

inch between the separated jaws. It was covered with white, thick coat, which later became a dirty brown. The saliva dropped copiously from the corners of the mouth, the submaxillary glands were swollen and hard. The eyes were slightly staring and the face wore an anxious look.

Being unable to articulate or swallow, the patient, by writing, made his wants known. He was very sure that he was going to choke to death, although he was told that there was very little danger of it. At his very urgent request, I remained with him during the night. The symptoms grew worse but the respiration was but little affected, so that tracheotomy was not anticipated, though preparations were made for it. Nutrient enemata were given also in the same way; the medicine consisted of whiskey, quinine, bromide and opium. During this night the disease was at its height. The patient suffered internally from sensations of choking, especially whenever he began to sleep, so that for this reason, he was afraid to sleep. The following day, which was the fourth day of the disease, the temperature was 100°, pulse 92, and the tongue was diminished in size, though the patient was still unable to speak or swallow. There was no sign of any pus formation, as far as we could judge. From this time the local symptoms gradually subsided, so that rectal feeding was necessary for 48 hours only. In a few days the mucus membrane of tongue and mouth was almost entirely free from coating, leaving a very red sensitive surface. For many days there was no taste and no desire for food. The temperature and pulse remained above normal for some time. This attack was followed by a general prostration marked by extreme nervousness, slight mental aberration, insomnia, slow return of appetite, so that more than three months elapsed before he was able to resume any work. Of course this long illness was the result of general exhaustion and cannot be considered a convalescence for glossitis, though undoubtedly the apprehension of choking (which he afterwards said he actually suffered for 36 hours) must have been something of a shock to his already weakened nervous system. The patient since then has developed phthisis and is now well advanced.

While in attendance upon the case just cited, I was called to see a young man of Irish parentage, of good family and personal history. Occupation, a plumber's assistant. He complained of sore throat and much pain in swallowing. On inspection I found the throat generally inflamed. The floor of the mouth on the left the side centering about the location of the sublingual gland was swollen and very tender. Under the chin of same side there was swelling and tenderness.

Poultices ordered for the neck and mouth were given. Thirty-six hours later I was sent for very early in the morning. The tongue was more than twice the normal size. The patient had not slept the previous night for fear of choking. The temperature and pulse normal. The area over the sublingual gland about the same size as before. He is able to swallow liquid fluids with difficulty. Calomel, grs. 10, to be followed in four hours by saline till the bowels move freely. Listerine for mouth spray and poultice continued.

Two days later a small abscess broke in the region of sublingual gland, but not, I think, in the gland. About 2½ oz. of foul pus discharged. The opening was dilated and syringed out daily with a weak solution of chloral for three or four days, when the tongue was nearly normal in size and patient practically well.

ABORTION AT FIVE WEEKS, WITH SUBSEQUENT EXAMINATION OF THE EMBRYO.*

BY T. RIDGWAY PARKER, M. D.

The following case is reported, not on account of the infrequency of abortion at such an early period of gestation, but rather with the hope that a full and detailed account, accompanied with a thorough examination of the embryo, which one is rarely successful in securing, may prove of interest to those devoting their time and attention to a heretofore much neglected subject:

M. S., aged twenty years, married, no children, gives the following history: Menstruation began at the age of thirteen years; she had always been regular in her menses, though at times the flow had been profuse, and accompanied by considerable pain. Her general health is good; there exists no kidney trouble nor specific taint of any kind. She last menstruated on November 6, 1890, duration five days. The discharge being normal in every respect, save that it was accompanied with some abdominal pain. On the arrival of her next period to menstruate, December 4th, there was no flow, nor any symptoms indicative of its approach. The

*Read before the Phila. Co. Med. Soc. June 10, '91.

patient was gratified by this state of affairs, as she believed herself pregnant. Week succeeded week without any appearance of her sickness, and hope continued to grow in her breast.

On the 26th of December I was called to see Mrs. S., whom I found very anxious and alarmed about her condition, as she had passed, she told me, a small clot of blood, and declared she felt as if her sickness was about to return, though it was not at a menstrual period. On questioning her further, I was unable to discover any symptoms of pain, and therefore merely advised her to keep quiet and avoid exercise of an exhaustive nature, as I feared should she fail to heed my words of caution that she might suffer from an abortion, it being my opinion, on examination of the vulva and mammæ, that she was some five weeks pregnant. While, of course, it was impossible to make a positive diagnosis at this early stage of gestation, still from the globular form of the breasts, the prominence of the nipples, and the dimpling at their summits, in addition to the purplish hue of the vagina, I considered such a supposition justifiable. As my patient was a blonde, the areolæ were faint, and could not, therefore, be regarded as of much importance. Nor were there sufficient gastric or nervous symptoms present to warrant me in expressing a more positive opinion.

On the following day I called to see Mrs. S., whom I found suffering great pain, which had come on during the night, and was paroxysmal in character, and referable to the back and hypogastrium. Her distress was of such an aggravated form that it was necessary to afford relief as promptly as possible by giving a hypodermic of sulphate of morphine. I learned on inquiry that during the night she passed several clots of blood, and that the flow had been so free that she was obliged to have frequent recourse to a change of napkins. The pulse, at the time of my morning visit, was quick and weak, and the temperature considerably above the normal. I determined, therefore, to explore the vaginal canal, and at the same time examine digitally as to the condition of the uterus. The cervix was discovered by the finger to be softened and the os slightly patulous, while the body of the uterus was enlarged and tender. Continuing my examination I felt several clots in the posterior fornix of the vagina; these I removed, which, on escaping into the palm of my hand, were found, in part, to consist of coagulated blood, but, in addition, an ovum with its membranes intact. This was placed carefully aside until my patient had been rendered more comfortable.

The treatment was generally symptomatic, consisting of anodynes and antipyretics, which seemed all that was required, as the hæmorrhage was slight, and not likely to increase, but rather diminish, since the uterus had expelled its contents. My attention was now directed to an examination of the product of conception. The ovum, to the naked eye, had the appearance of a pale-yellow vesicle, save where the crimson shaggy villus processes projected from the chorionic membrane. The whole mass measured six-tenths of an inch in diameter, while the length of the villi averaged only one-tenth. At the point where the outer portion of the chorion had been torn off from the ovum (indicating the place of separation of the ovum from the decidua), the membranes were so thin and transparent that the eye could clearly discern through them the diminutive embryo, but one-fifth of an inch in length, surrounded by its amnion, which closely invested it. From its caudal extremity could be seen the allantoic stalk extending out to the periphery of the ovum where it fused with the subzonal membrane. The direction which this vascular outgrowth was observed to take was, first, at right angles to the long axis of the embryo until it passed beyond its inferior extremity, when it made an abrupt turn and changed its course so as to run parallel to longitudinal axis. Two vessels of a crimson color were visible, but they could not be traced to the periphery, though very distinct for more than half the length of the allantoic stalk. That portion of the ovum from which the chorionic layer with its villi had been torn off was directly at the point where the duct of the allantois joined the outer ovular membranes. In other words, the outer layer of the chorion with its villi had been separated from the ovum at what one may reasonably suppose to be the placental site. Hence one is justified in concluding that the villi in this locality were larger and more deeply imbedded in the placental decidua (decidua serotina) than at any other point. Further, that the ovum was lost, not on account of any morbid state of the uterine mucus membrane, but through traumatism, the source being unaccounted for and unknown. The villi appeared perfectly normal, and were of a bright crimson color. As regards their structure and development, there was nothing suggestive of any pathological change having occurred. By means of a keen, delicate instrument it was possible to dissect the membranes entering into the

formation of the chorion, and expose three layers to view.

The external, from which the villi were outgrowths, being the opaque altered vitelline membrane; the middle, thin and transparent, I judged to be the remains of the zona pullucida and false amnion (subzonal membrane), while the third and internal, similar to the middle coat, represented the membranous portion of the allantois. Of these three separable membranes making up the chorion, the external alone was opaque. The ovum was slightly heavier than water, yet did not sink to the bottom of the phial in which it was placed, the villi seeming to buoy it up. Beneath the chorion and enclosed by it was a space filled with some thirty minims of a clear, highly refractive fluid, almost colorless, separating the chorionic walls from that of the amnion.

This fluid was of a neutral reaction. Cutting through the layers of the chorion, the fluid was permitted to escape, but did so very slowly, as there existed delicate bands of fibres extending from the amnion to the chorion. These fibres did not cross each other, but radiated from the diminutive amnion, like the spokes of a wheel. It became necessary to divide these before the embryo with its membranes (amnion) could be liberated. The allantoic attachment was not, however, disturbed, that the relation of the parts might not be disturbed. Having freed the amnion, it became advisable to extend the examination so as to include the embryo and its appendages.

The umbilical vesicle had undergone atrophy, and was apparently quite empty. It inclined toward the abdomen of the embryo, and was scarcely as large as its neighbor. It was pear-shaped, and resembled a balloon that had almost collapsed. No vessels of any kind were visible in or upon its walls, which were corrugated and shrunken.

Proceeding next to a microscopic examination of the embryo by means of low and high power objectives the following structures were studied: The embryo occupied a position at the centre of the ovum, where it remained almost stationary, being held in place partly by the amnion and its chorionic fibres, and partly by the allantois. It was a yellowish-white, opaque, gelatinous mass of matter, soft and friable.

The outer covering consisted of round nucleated embryonic cells closely packed together. The long diameter of the embryo, corresponding to the vertebral axis, was one-fifth of an inch in length, while its transverse diameter was not more than one-fourth as great. No eyes were visible, though diligently sought for, nor was it possible to discover even rudimentary upper or lower extremities. The caudal portion of the embryo was very distinct, and being slightly transparent one could see without difficulty the segments of the notochord and the embryonic vertebral arches in their processes of development through the outer covering. The abdominal walls were still separated, and hence there existed a direct means of communication between the umbilical vesicle and the visceral cavity. The cephalic extremity of the embryo presented nothing peculiar nor characteristic, being simply a rounded mass of matter, similar in appearance to that making up the body walls. The line of demarkation between the head and the trunk was but a constricted portion, which represented the neck. No bronchial arches were made out, nor the presence of any oral cleft. Examination of the deeper structures was rendered impossible by the rapid disintegration of the tissues.

As regards the patient, after a week's rest in bed, necessitated by the nervous prostration incident to the sympathetic disturbance, she regained perfectly her health and strength, and there remained no uterine or other unpleasant sequelæ.

In this report of my examination of a five weeks embryo and its coverings I am well aware that there are statements quite at variance with those recorded by several authors, among whom may be mentioned Hirst, in his *System of Obstetrics*, vol. i., wherein is stated, page 129: "In the human embryo the period during which the umbilical vesicle increases in size ends at about the sixth week; then its rapid diminution commences." Yet, in my specimen, I found the vesicle almost empty, much atrophied, and its walls shrunken at five weeks gestation. Again, as to the number of coats comprising the chorion: by nearly all the authorities it is said to consist of but two—externally, the subzonal membrane; and internally, the allantois—through the disappearance of the vitelline membrane, zona pellucida, and internal lining membrane of the primitive ovum. Yet, when I began the dissection of these chorionic layers, I found it possible to separate *three* distinct membranes as described above. The villi were further noticed to be outgrowths from the external layer, not being imbedded in anyway in the underlying structures. As to

the absence of eye-spots and rudimentary extremities I have no satisfactory explanation to offer. This lack of development may have been due to an insufficient supply of nourishment, or subsequent investigation may prove these structures to appear at a later stage of gestation.

SELECTED FORMULÆ.

ARISTOL.

Richtmann recommends replacing iodoform in all cases by aristol. The latter is non-irritant, and its odor is not disagreeable. Its only drawback is its insolubility in water. It may be prescribed in powder, in ointment or in solution. The following are the formulæ that the author employs:

℞ Aristol.....gramme 1.
Ether.....grammes 10.
S. For external use.

℞ Aristol.
Castor oil, aa.....gramme 1.
Collodion.....grammes 8.
S. To paint the affected parts.

℞ Aristol.....grammes 2.
Vaselin.....grammes 18.
S. To apply on the affected parts.

℞ Aristol.....grammes 3.
Olive oil.....grammes 20.
Lanolin.....grammes 77.
S. To apply on burns.

—*Nouveaux Remédes.*

REMOVAL OF MOTHER-MARKS.

The *Allgemeine Medicinal Central Zeitung* gives the following as very efficacious: Mix one part of tartrate of antimony with four parts of emplastrum saponatum and work into a paste. Apply the mixture over the mark to be removed to the depth of one line (one-twelfth inch), and cover with a strip of gummed paper or court plaster. On the fourth or fifth day suppuration sets in, and in a few days later scarcely a sign of the mark can be seen.—*Amer. Med. Jour.*

ECZEMA OF THE ANUS AND GENITAL ORGANS.

Lustgarten advises the following ointment:

℞ Oleate of cocaine.....gr. xij to xxiv.
Lanolin.....f℥i.
Olive oil.....f℥ij. M.

Apply twice daily, and after each application powder the affected part with an absorbent powder.

FUMIGANT FOR ASTHMA.

℞ Stramonium leaves } of each..... ℥ j.
Green tea }
M. Lobelia inflata.....℥ iij.

Add a saturated solution of potassium nitrate, dry, and preserve in a well-stopped bottle. A teaspoonful suffices for a fumigation.—*La Sem. Med.*

STYRONE IN CHRONIC PURULENT OTITIS MEDIA.

Cheltsoff ascribes great value to styrone in the treatment of middle-ear disease. Very good results were obtained by syringing with the following:

℞ Styrone.....gr. xx.
Alcohol..... f℥j.
M. Sig. One part of the above to 20 parts of water.

FOR ANTHRAX.

Dr. Spohn, in the *Semaine Médicale*, recommends the following application in anthrax:

℞ Chloral. hydrat.....grammes 20.0.
Glycerini
Aq. distill., aa.....grammes 90.0.
M. et Sig. For external use.

Gauze kept constantly wet with this solution, should be applied to the anthrax. Any incision is deemed superfluous.

PURULENT OTITIS MEDIA.

Pentkowski, in the *Duetsche Med. Wochenschrift*, recommends the following treatment for purulent otitis media.

The ear should first be syringed out with a warm solution of sulphate of soda, and after being cleaned again, syringed with the following solution:

℞ Ol. menth. piper.....gramme 0.18.
Solve in alcohol. absolut.....gtt. 75.
Aq. dest.....grammes 100.0.
M. Sig. For external use.

Then a pledget of cotton soaked in the following mixture is inserted into the ear:

℞ Ol. menth. piper.....gtt. j.
Aether. sulph.....gtt. 100.
M.

By daily applications of this kind, Pentkowski claims always to have obtained a complete cure within two weeks. In all other cases, where the patients cannot come for daily treatment, he prescribes a powder composed of boracic acid with 1 per cent. of ol. menth. piper., as an application.

ANTIPYRIN IN BLENORRHAGIA.

Brenisa, in the *Journal de Méd. de Paris*, recommends the use of antipyrin in blenorrhagia, prescribing it in the following formula:

℞

Antipyrini.....grammes 3.0.
Zinci sulphatis.....gramme 0.3.
Aq. rosæ
Aq. lauro-cerasi. aa.....grammes 60.0.

M. Sig. For urethral injection.

ZINC GLUE FOR STIFF SURGICAL DRESSINGS.

Treutler recommends a preparation, first suggested by Unna, for obtaining stiff surgical dressings, such as are applied to fractured or dislocated limbs. It is as follows:

℞

Oxide of zinc.....parts 10.
Gelatin.....parts 30.
Glycerin.....parts 30.
Water.....parts 30.

This is thickly applied and rubbed into the muslin or gauze forming the bandage. A thinner preparation contains 20 parts of gelatin and 40 parts of water, the other ingredients remaining the same.—*Med.-chir. Rundschau.*

CHRONIC RHEUMATISM.

The clothing of the patient must be attended to. It is essential that flannel should be worn next to the skin. The Jäger underclothing is very good. The diet should be nourishing, and, if stimulants are required, a little whisky is, perhaps the best. The internal treatment adopted is very various. I have found the following prescription most useful:

℞

Pot. bicarb.....gr. xv.
Pot. iod.....gr. iij.
Tr. hyoscyam..... ♏ x.
Spt. chlorof..... ♏ v.
Inf. gentian..... f℥ss.

M. S. Ft. haustus, ter in die.

In strong adults, a few drops of vin. colchici is beneficial. I have seen good results from three-grain doses of salicylate of soda three times daily. Gaiacum is useful in some cases.

As the patient progresses, a mixture of the following may be given:

℞

Ferri et ammon. cit.....gr. x.
Pot. iod.....gr. iij.
Pot. bicarb.....gr. xij.
Spt. chlorof..... ♏ v.
Aquæ pimentæ..... f℥j.

M. S. Ter in die.

The syrup ferri iodidi answers well in some cases. If there be much pain, opiates, especially given subcutaneously are often of marvelous efficacy. If the patient is debilitated, cod-liver oil is useful.—STAPLE, *Hospital Gazette.*

HOW TO GIVE CASTOR OIL.

The *Dixie Doctor* says to administer castor oil pleasantly, thoroughly mix the dose with four times as much hot milk, shaking the two together in a bottle which they do not more than half fill. When taken in this way the activity of the oil seems to be increased, and being rendered very limpid by the hot milk its oily nature is not perceived. It is scarcely to be distinguished from hot milk.

GLUCOSE TO COVER THE TASTE OF IODINE.

The administration of iodine uncombined is usually objectionable to the patient, yet in many chronic disorders it is preferred by some practitioners to any of its saline combinations. Its difficult solubility in water alone is a hindrance to giving it in this condition, owing to the quantity of a simple aqueous solution necessary for a dose. Sugar not in its ordinary condition is unsatisfactory as an admixture, but it is found that glucose can be utilized much more acceptably. Dr. F. P. Mann, of San Francisco, suggests the following formula, and prefers that the form of glucose should be that of molasses, and that the mixture should be made for at least one day before it is administered:

℞

Iodinii.....f℥ss.
Potass iodidi.....℥ijss.
Aquæ pura.....f℥iv.
Syrup fuscus.....f℥xij.
Ess. gaulth.....f℥ij.

M. ft. sol. sig. Take teaspoonful between each meal, with a little water.

—*Phar. Rec.*

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

EDWARD T. REICHERT, M. D.,

PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF PENNA.,

EDITOR AND MANAGER.

N. E. Cor. 13th and Walnut Streets,

P. O. Box 843. Philadelphia, Pa.

THE MEDICAL AND SURGICAL REPORTER.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent 3 months on trial for $1.

At the termination of the period of subscription, we will promptly discontinue sending THE REPORTER unless directed to the contrary by the subscriber.

Remittances should be made by draft, check, postal note, or money order payable to Edward T. Reichert.

THE POCKET RECORD AND VISITING LIST.

Two sizes. Prices to subscribers of THE REPORTER: For 30 patients a week (with or without dates), $1.00. For 60 patients a week (without dates), . . $1.25. Prices to non-subscribers, $1.25 and $1.50 respectively.

THE MODEL LEDGER.

Physicians who keep their own books will find this of great value. Sample pages sent on application. Price, $5.00.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If THE REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS.

Write in ink.

Write on one side of paper only.

Write on foolscap or legalcap paper.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be pleased to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

LEADING ARTICLE.

THE ANÆSTHETIC PROBLEM:— ETHER VS. CHLOROFORM?

The controversy as to the relative merits of ether and chloroform as anæsthetic agents is being carried on vigorously abroad, and it is next to impossible to pick up a foreign medical journal without finding some allusion to the subject under consideration. One of the most valuable papers on this topic recently published, is by Dr. Julliard, a leading surgeon of Geneva, which appeared in the *Revue. Médicale de la Suisse, Romande* February, 1891, and is made the subject of an editorial in the London *Lancet* for April 25, 1891. In this paper Professor Julliard describes how he was first led to investigate the merits of the two anæsthetics; owing to the death of one of his patients by chloroform during the reduction of a dislocation; and in 1877, he began to employ ether. Since that time he has had no accident in 3,654 cases of operation.

He points out in this brochure the fact that both drugs will destroy life if pushed beyond a definite point, and he discriminates between their normal physiological result and the accidental effects they occasionally produce. Both agents may, he asserts, produce primary or secondary arrest of respiration, with this difference, that the arrest of respiration by chloroform is nearly always sudden, while that occasioned by ether is, as a rule, gradual. He also mentions the fact that the cessation of respiration from chloroform narcosis is more liable to be permanent, and artificial respiration of less use in the attempts made to restore the normal functions of the respiratory mechanism, than is the case in narcosis resulting from the use of ether.

Regarding the influence of chloroform on the heart, Dr. Julliard notes the difference between the primary syncope occurring during the early stages of chloroform inhalations and the secondary syncope which is liable to occur during profound anæsthesia. The syncope of the early stage of chloroform anæsthesia is sudden and dangerous, while the secondary syncope is slower in its onset and

is nearly always preceded by cessation of the respiration.

In etherization, Dr. Julliard is convinced that the tendency to primary syncope is much less frequent than in chloroformization. Death occurs much more frequently with chloroform before the stage of complete anæsthesia than with ether. This statement he supports by statistics, in which he shows that of 243 cases of death by chloroform, more than one-half occurred before anæsthesia ensued, while in 60 cases of death by ether only 4 happened before the operation began.

Dr. Julliard confirms the general opinion expressed by unbiased anæsthetizers that secondary syncope is less common with ether than with chloroform; he likewise concurs with the prevalent opinion, in this country, at least, that the danger from chloroform is mainly the production of heart-failure, while that from ether is largely due to failure of the respiratory apparatus. He also points out the fact that artificial respiration is of more avail in this latter condition, arising from etherization, than it or other efforts made to restore the heart's action when that organ stops in the primary syncope arising from the employment of chloroform.

Dr. Julliard gives as his own experience with ether, covering a period of 14 years, that out of 3,654 administrations he has not had a death, and adds: "Not only have I not had any deaths, but I have had no alarming accident. I have not once had to resort to artificial respiration, neither have I had to interrupt an operation in order to ward off any accident, due to etherization. I cannot say as much for my chloroform administrations." This statement is certainly a glowing tribute to the safety of ether, by one who was formerly a strong advocate of the use of chloroform.

In a valuable statistical summary, gathered from various sources, Dr. Julliard is enabled to prove the comparitive safety of ether over chloroform: In 524,507 cases of chloroform anæsthesia there were 161 deaths, or 1 in 3,258; while in 314,738 cases of etherization, only 21 deaths occurred, or 1 in 14,987. A mortality from chloroform four times greater than from ether.

Dr. Julliard sums up his arguments by stating:

1. That anyone who is anæsthetized by chloroform or by ether, in a measure, jeopardizes his life; and

2. That the danger involved is five times less with ether than with chloroform.

In reference to the asserted dangers and disadvantages of ether, Dr. Julliard considered no less than eighteen objections to the drug. We reproduce here a few of the points he considers with his comments made thereon:

1. Ether is disagreeable. This is a matter of taste and is hardly worthy of consideration, in view of the risk.

2. Ether is less active than chloroform, and the anæsthetic effect is more slowly produced. This Dr. Julliard admits, but considers that the delay is amply compensated by the additional safety of the drug.

3. Vomiting is more common after ether. This he proves to be untrue, according to statistics and his own experience.

4. Ether excites bronchial secretion. Dr. Julliard states this is a rare occurrence and that such a tendency of the drug is much diminished by the subcutaneous injection of morphine and by administering a well-diluted vapor of the anæsthetic, etc.

We have quoted somewhat freely from the paper of Dr. Julliard for several reasons:

1. Because of the continued dispute, abroad and even in our own country, as to the relative anæsthetic value of the two drugs —ether and chloroform.

2. Because Dr. Julliard, who is a surgeon of note and a former advocate of the supremacy of chloroform as an anæsthetic, has by reason of a thorough trial of ether reached the conclusion that it is not only the more satisfactory anæsthetic but is also the safer agent of the two.

In conclusion, we would refer briefly to a practical point of some considerable importance, which is alluded to in Dr. Julliard's paper, to wit: the use of morphine previous

to etherization, for the purpose of favorably modifying the action of the anæsthetic. Morphine, to be used in this manner must be given hypodermically in the dose of one-sixth to one-third of a grain, to an adult, at least *forty minutes* before beginning the administration of ether; otherwise, if the operation is to be commenced immediately, according to an extensive series of observations made by Wm. Rigaud and Sarazin, at the hospital of Strasburg, an injection of morphine will augment the period of excitement, and if the dose be tolerably large, accidents on the part of the respiratory mechanism may occur.

The administration of an opiate, in the manner directed, is claimed to act happily in reducing the stage of excitement and the tendency to vomiting; it is also said to promote the subsequent rest of the patient by inducing sleep and to lessen by one-half to one-third the amount of the agent employed to induce anæsthesia.

This plan of modifying the anæsthetic process by hypodermic injections, was first practised by the eminent Munich surgeon, Nussbaum, who published the results of his experiments in the *Bavarian Medical Intelligencer*, for October, 1863.

We are aware that a difference of opinion exists as to the beneficial effect of opium used in combination with either of the anæsthetics named. Most of objectors to the practice of mixed anæsthesia, admit that the employment of morphine and chloroform is open to less objection than the same use of morphine and ether.

The objection urged ugainst the use of a narcotic in these cases is, that in combination with ether, opium is apt to produce a great tendency towards respiratory failure; and in the case of its administration before resorting to chloroformization, it is liable to provoke undue excitement and emesis.

In our opinion, when an operation is to be a protracted and severe one, an opiate in combination with a moderate dose of atropine, hypodermically, does good and lessens the period of ether excitement as well as the amount of the anæsthetic required.

The atropine acts happily as a reliable cardiac respiratory stimulant.

There is no question in our mind, that whenever morphine is so used, it should be given in combination with atropine. *As a preventive of accident, atropine is undoubtedly far more reliable than as a means of rescue when such has occurred.*

A most valuable essay upon the subject of the anæsthetic process by the hypodermic injection of narcotics is to be found in the article of Dr. J. C. Reeve, of Dayton, Ohio, published in the *American Journal of the Medical Sciences*, April, 1876, p. 374.

CORRESPONDENCE.

A PROTEST AGAINST THERAPEUTIC PSEUDO-SCIENCE.

To the Editor Medical & Surgical Reporter:—

A certain famous Talmudist, Maimonides by name, was justly esteemed wise as a physicion as well, if for no other reason than that he enunciated and followed this rule of procedure for each case entrusted to his care. On the first visit he confined his attentions to thorough examination; on his second he administered simple remedies such as are found in ordinary households, regulating meanwhile the environment; on his third he was prepared to give drugs if indicated. It goes without saying that under such circumstances these last came in for little enough use to satisfy almost the therapeutic nihilist. Limitless lessons might be drawn from the dictum of this wise yet little known philosopher and it is to be hoped that his rule of action will obtain the consideration, through the widely influential pages of this journal, which it richly deserves. I have but a word to say concerning the middle proportion and wish to point out how large a field of usefulness might be covered by a critical scientific search into those curative agencies called domestic remedies; also to note the value of relentlessly pursuing our grossly exuberant advanced therapeutics.

It is quite the fashion nowadays among eminently conservative medical men to shout and sing pæans on the appearance of a new compound which its enthusiastic supporters have hastily percolated through the various "systems" of patient beasts in Physiological Laboratories or yet more un-

resisting culture media. Add to this further dilution through the tissues of unsuspecting and perhaps emotionally benefited dispensary patients. Thereupon, these judicious observers, backed up by a great array of observations, confidently raise the banner of the new wonder worker.

The medical press discriminating gravely against fanciful assumptions, is reluctantly induced to publish all this. Editorials are written in a style strangely like the articles from the laboratory and hospital, gravely asserting that wondrous truths are thus, and now under Providence, made known.

Meanwhile a modicum of reward in the shape of public notice is shed like dew upon these observers. This may not be always covert self-laudation nor advertisement, certainly. It is love of scientific knowledge in the main, though seeming oftimes otherwise.

Such researches moreover have proved not seldom to be rounds in the ladder of fame to many bright medical lights. Assuredly much of incalculable value is thus set forth but here and there the impostor gains credence from his worthy company and because his walk and conversation, being entirely in the mode, so closely resemble the true student.

All praises to the self-forgetful toilers who, from pure impulses, searching out the dark mysteries of nature and disease have, in season and out of season, added to the sum of medical knowledge.

The great Trousseau said long ago, when Empirical Therapeutics, then emerging from the fogs of undigested prejudices, began to accept the explanations of experimenters, "distrust medical theories that originate in the laboratory. Although chemistry may be the handmaid of medicine she goes beyond her sphere when she applies the conclusions of the laboratory directly to the treatment of the sick. Chemistry stands little nearer to medicine, because she teaches us how to prepare or to analyze medicines than she does to the art of painting because she prepares the painters' colors."

This is as true to-day as then—both as to the chemical and physiological laboratory.

Too much honor cannot be given to the myriads of unrewarded students who have placed medical knowledge on its present pinnacle of public confidence. The human race is their hereditary and perpetual debtor for what they have done and are constantly doing. Too much confidence can be and is all the while being shown to the impostors, conscious or unconscious, who pose as scientific searchers and teachers.

It is the plain duty of medical men, particularly the great body of conscientious general practitioners looking with reverence upon the great teachers, to cry aloud and denounce those who by accident or design distort the waves of thought in the smallest particular.

There is but one quality which fitly adorns and conditions science, and that is accuracy. This involves unbending honesty of purpose in the arrangement of facts and the record of observations from whence, through much purification, comes the perfect truth.

Judged by this severe standard a very large part of recent medical literature would be found wanting. Whole volumes even now lie neglected on library shelves not yet written a score of years. These are not valueless, perhaps; at least they may serve as landmarks of progress, but they are exceedingly cumbersome and clog the student's movements overmuch.

My object here is merely to sound the note of revision and reconsideration. To begin pretty far back moreover, and not lose sight of the too much neglected old-fashioned remedies—remedies the utility of which was fairly established by wholesome minded enquiring empiricism—that process of practical evolution to which good and safe medical practitioners owe so much, but being no longer fashionable is now sneeringly ignored. And again to point the sceptical finger at the hastily constructed masses of pseudo-scientific facts which, since they are the fashion, pass current for reputable data.

To be sure it may be answered that this process of selection goes on unconsciously and steadily; that human thought works out its own problems in time unassisted. Not so. Elimination and intelligent selection cannot be dispensed with.

Guiding hands exercising the quality of judgment will be needed among all peoples and nations "till Shiloh come."

Thoreau in his clean hearted contempt for conventional restraints somewhat sweepingly but with much force says, that the true vocation of the scholar is "to unlearn the first ideas of history, of science, of social institutions, to unlearn even our own life and purpose; to unlearn the old mode of thought and way of arriving at things; to take off peel after peel, and so get by degrees slowly towards the truth."

If this discriminating power be not ever needful, upon the failure of what selective influence can we place the blame for such a

wretched fiasco as the Koch's lymph episode?

Here a nation enjoying the reputation for greatest gravity and refinement of knowledge upon the occasion of a great international festivity and opportunity for self-glorification, looks about for a hero or a victim. They seize upon a student in his laboratory, who has modestly announced himself on the verge of a great discovery and with ruthless hands drag him protesting to disgorge his grand idea in undigested shape for their gratification; literally "butchered to make a Dutchman's Holiday." They bandy his pearl of possible wisdom about in filthy hands subjecting it to worse than destruction and finally, when unable to use it, hurl it back with curses in his face.

Why also is a large part of the so-called intelligent community yet fondly hoping, yea, fully expecting, marvellous curative results to come from the shrewdly handled mysticisms of homœopathy?

No reasonable doubt can linger in the mind of an intelligent man who may give these facts his attention but that more discredit comes upon the art of medicine from the barnacles of garbled, distorted, ill-digested and putrefying masses of falsely scientific fact and belief than from a too conservative or narrow minded neglect of the wondrous truths constantly opened up to us.

That these matters right themselves if let alone is no more true than that the body rights its functions unassisted.

This self-regulation of the bodily organs does frequently occur but more often demands judicious aid.

The man who keeps ever a watchful critical eye open to point out and correct the diseased tendencies of medical thought will do almost as much for truth as he who makes new and pyrotechnic discoveries.

And finally, is it not the plain duty of all conscientious medical men to stand ready to pull down or denounce false beliefs ever and always?

J. Madison Taylor.

A CORRECTION.

We are in receipt of a letter from Dr. Edward Vanderpoel, of New Suffolk, N. Y., relating to a typographical error in his letter to us, which appeared in the Reporter for August 8. The doctor says:

"In the prescription I gave, the mistake has been made of stating that it was for *five* pills, instead of for *one*. The corrected formula should read as follows:

℞ Chlor. hydrarg. mit.....gr. ij.
Ex. hyoscyan.....gr. jss.
Podophyllini.....gr. ⅙.
M. For *one* pill.
Signa. One pill to be taken every two hours until relieved."

Book Reviews.

SEXUAL NEURASTHENIA—ITS HYGIENE, CAUSES, SYMPTOMS AND TREATMENT, WITH A CHAPTER ON DIET FOR THE NERVOUS. By George M. Beard, A. M., M. D., Formerly Lecturer on Nervous Diseases in the Univ. of the City of New York, etc. Edited by A. D. Rockwell, A. M., M. D., Prof. of Electro-Therapeutics in the N. Y. Post-Graduate Medical School and Hospital, etc. Third Edition, with Formulæs, 8 vo. pp. 282. New York; E. B. Treat & Co., 1891.

This work is one of a series, by the late Dr. Beard, upon the various manifestations of neurasthenia. Those who have not made themselves familiar with the relation existing between sexual disorders and neurasthenia will find the book both instructive and interesting. Discussing sexual topics, the author enlarges sufficiently for the information of the reader, without relating details which appeal only to a prurient and unwholesome curiosity. The style of the book is the reverse of concise, and it contains much matter which relates to neurasthenia in its general rather than in its sexual aspect. In a future edition the Editor might condense it very considerably with advantage.

The chapters discussing the relation of neurasthenia to insanity, the similarity in the symptoms of sexual neurasthenia in the two sexes, the relation, or rather in general the absence of relation between masturbation and genital disease and neurasthenia, are all interesting.

The author is a strong believer in treatment directed to the mind of the patient in combating his disorder, and in this regard all men of experience must agree with him. To remove illusions and despondency, and to supply the basis of hope, and healthy mental activity is undoubtedly almost the *sine qua non* in the successful management of the disease.

A judicious use of roborants, local and general sedatives, and electricity, is also insisted upon. A highly nutritious meat diet

is advised. The author's remarks on travel as a cure are of great interest. One needs a good constitution to travel with pleasure or with profit; and persons who are very sick are usually made worse. Especially the man of limited income, who can ill afford to lose time from business, and still less to incur the extraordinary expenses incident to travel, is seldom benefited. The mental anxieties brought about by travel and expense counterbalance the good received.

PERISCOPE.

THERAPEUTICS.

BROMIDE OF ETHYL IN EPILEPSY.

Dr. J. Donath, of Budapest, reports that when using bromide of ethyl in 0.1 gramme to 0.3 gramme doses, two or three times daily, in cases of epilepsy, the attacks become much milder and of shorter duration, indeed in some cases the improvement goes so far that the epileption attacks give way to mere muscular contractions without loss of consciousness. When exhibited internally, the drug is best given in suspension, as follows:

℞ Aethylein bromati..... grammes 5.0.
Ad. emuls. oleos..... grammes 100.0.
Ol. menth. piper..... gtt. ij.

M. Of this emulsion an adult should be given 30 drops two or three times a day, in a third of a tumblerful of water. This dose should be gradually increased to 70 drops (halfa teaspoonful). Children of ten years of age should begin the treatment with doses of 10 or 20 drops.

Another formulæ is the following:

℞ Aethyleni bromati.....
Spirit. vini. rectificati..... aa. grammes 5.0.
Ol. menth. piper..... gtt. ij.

M. et Signa: 5 to 15 drops in a third of a glassful of milk two or three times daily.

Finally the drug may be advantageously administered in gelatin capsules, the following formulæ being used:

℞ Aethyleni bromati..... gtt. iij.
Ol. amygdal. dulc..... gtt. ij.
D. t. d. in caps. gelat. nos. 100

Signa: 2 to 4 capsules two or three times a day.

If there is an increase of the epileptiform attacks subcutaneous injections of the drug, best given in oily solution, are recommended.—*Münchener Med. Wochenschrift*, July 21, 1891.

THE ANALGESIC ACTION OF ANTIPYRETICS.

Dr. Bernheim, in the *Journal des Sciences Médicales de Lille*, draws attention to the analgesic action of various well-known antipyretics, including quinine, salicylic acid, antipyrin, antifebrin, phenacetin, etc.

When the beneficial effects of salicylic acid in articular rheumatism were first noted, the profession was prone to regard the remedy as a specific in this disease. Experience has, however, taught us that other antithermics as well, possess the same properties, that is to say, that they speedily relieve the articular pain, but without influencing the course of the disease, or exerting any true curative action. The connection between this antipyretic and analgesic action Bernheim essays to explain as follows: Fever occurs by the absorption of pyrogenous substances in the blood, or by the direct influence of the caloric center. Were our antithermics really capable of destroying these ferments in the blood, they would all exert an abortive action upon fevers. This is, however, not the case; indeed Bernheim even refuses to admit a specific action of quinine in malaria, but explains the checking of the morbid process, as a consequence of the absence of fever brought about by the drug's action, and asserts that the same end could be obtained by any other efficient antipyretic. He concludes, therefore, that the various antipyretic remedies, including quinine and salicylic acid, act only as such, in that they effect a cerebral center as antithermics, and that, on the contrary, their "antipyretic" action within the organism is not proved. Their analgesic action is very closely allied to their antithermic action. The former being caused by an action on the nervous centers. In fact, Bernheim has been able, by means of the æsthesiometer, to demonstrate a decreased sensibility of the skin, after the exhibition of quinine. Antipyretics, according to Bernheim, are only indicated in febrile diseases, when the height of the temperature is a menace to life, or when the lessening of an abnormally increased sensibility to pain is desired.

THYMOLO-ACETIC MERCURY IN THE TREATMENT OF SYPHILIS.

Dr. Migneco, in a recent number of the *Riforma Medica*, reports the results obtained in the Catania Clinic for Specific Diseases, with thymolo-acetic mercury (hydrargyrum thymolo-aceticum) in the treatment of syphilis. The remedy was administered by injection in the gluteal region, each time 75 milligrammes of the preparation as follows was injected:

℞

Hydrarg. thymolo-acet..... grammes 1.50.
Mucilag. gum. arab..... grammes 0.50.
Aquæ. dest..... grammes 20.0.

M.

In the eighteen reported cases, 250 injections were made. The average duration of the treatment was 33 days. An exact examination of the urine revealed the fact that mercury could be found in moderate quantities eight hours after an injection had been made. No local reaction was occasioned by the treatment. In comparison with bichloride of mercury it is far superior, although it is insoluble. Its action is much more prompt, and relapses apparently occur less frequently.

THE EMPLOYMENT OF EXALGINE IN INFANTILE THERAPEUTICS.

Dr. Moncorvo, in the *Bull. Thér.*, writes that his researches have been carried out on a total of twenty-one children from the age of one and a half years to twelve. In all these cases the exalgine was given to combat the element of pain, and he was obliged to confess that it much exceeded his expectations. In fact, in not a single case was he disappointed in its effects, and in every instance tolerance was perfect. There was no dizziness, ringing of the ears, or other unpleasants effects observed. Ordinarily the action of the drug was easily obtained, amelioration of the pain being generally established in an hour after the administration of the drug, not rarely it was quite abolished by that time.

He has often given the remedy many days in succession without the least sign of intolerance. In this way he has, in some of his patients, cured definitely, neuralgias and migraines which had dated from a long time back, and which resisted all other therapeutic agents.

The cases treated were as follows:

Neuralgia	2 cases.
Migraine	4 "
Otalgia	1 "
Odontalgia	2 "
Gastralgia	2 "
Hepatalgia	1 "
Pleurodynia	1 "
Dry Pleurisy	1 "
Articular Pain	2 "
Otitis	2 "
Torticollis	1 "
Pott's Disease	1 "
Lymphangitis and Arthritis	1 "
Total	21 cases.

In all his cases exalgine has, without exception, succeeded; that is to say, it always acted as an analgesic.

An apparently small dose of the drug will frequently triumph over the most tenacious pain, its analgesic power being very far from being in proportion to the size of the dose. From this point of view it appears to him to have a decided superiority to antipyrin, at least as regards children.

Great energy with the most complete innocuousness in moderate doses are the two points which recommend the use of this new agent in infantile therapeutics. It was usually given in solution with an agreeable tincture or essence containing a little alcohol. In the older cases it was sometimes given in wafer paper or capsules, and sometimes the dose was placed on the base of the tongue and washed down with a swallow of wine and water.

In regard to posology: Being somewhat timid with his first cases he began with 5 cgm. (¾ gr.) a day, but soon finding the tolerance absolute, he progressively augmented the dose up to 30 cgm. (4½ grs.) in the 24 hours, and this last dose has been as well supported as that of 5 cgm.

Considering the claims of exalgine as a nervine he mentions a case, previously published in THE REPORTER, of chorea in a child eight years old, with very nervous antecedents. The chorea was very marked and the movements did not cease even during sleep. The dynamometric force was eight kilos for the right and six kilos for the left hand. Treatment consisted of 10 cgm. (1½ grs.) of exalgine twice daily with the result of the complete disappearance of the choreiform movements and great general improvement.

The following are the conclusions reached:

1. The great activity of exalgine as an analgesic has been, without exception, well demonstrated in these twenty-one diverse cases of pain.

2. In children complete tolerance has been established, and in no case was there any appearance of disagreeable results.

3. The initial dose should be five cgm. (¾ gr.) a day and rise progressively to 30 cgm. (4½ grs.) a day.

4. The drug may be given in any acceptable way—solution, capsule, or placed on the base of the tongue and washed down by a swallow of wine and water.

5. Exalgine surpasses antipyrin in activity, even in cases where the dose of the latter is five times as great.

6. The value of the drug as a nervine seems probable from the results obtained in one case of chorea.

SEA-SALT FOR INSECT BITES.

According to the *Deutsche Med. Wochenschrift*, sea-salt is an excellent application for the sting of bees, wasps, and other insects. The parts stung are rubbed with the salt dissolved in water. Pain and swelling disappear immediately, or, if the treatment is used at once, do not appear at all.

MEGHANICAL TREATMENT OF THE STOMACH.

Dr. Cseri (*Pest. Med. Chir.*) claims to have achieved the most brilliant results in the treatment of chronic digestive disorders by the employment of massage of the stomach, supplemented by regulation of diet.

The massage is practised while the stomach is full, *i. e.*, two or three hours after the chief meal. It consists in, for 10 or 15 minutes, rubbing and kneading the stomach, from the fundus toward the pylorus, at first gently, but afterward more forcibly. During the operation the patient lies on his back, having his kees drawn up, and breathing with his mouth open. After the stomach has been thoroughly kneaded, the massage is extended over the intestines.

The manipulation is not at all painful; it rather produces a feeling of warmth and comfort in the stomach. After several sittings, the feeling of depression and gastric oppression, common in dyspepsia, disappears.

Being practised two or three hours after meals, that is at a time when part of the ingesta are entering the duodenum, the massage assists the progress of the gastric contents, and also relieves the stomach somewhat of the gases which are present in it about this time. It tends, furthermore, to restore the impaired gastric peristalsis.

Cseri claims that massage widens the pylorus, so that it no longer resists the passage of the food, thus relieving the troublesome pains so common in nervous dyspepsia. But massage is useful in dilatation of the stomach, as well as in nervous dyspepsia.

Of course, ulcers and new growths of the stomach are a positive contraindication to the massage treatment.—*West. Med. Rev.*

TREATMENT OF TOXIC AMBLYOPIA.

The following summary of treatment of various toxic amblyopias is given by Chaltin (*L'Union Médicale*, May 2, 1891):

1. *Alcoholic Amblyopia.*—Immediate abstinence from alcoholic drink. Improve nutrition by tonics and diet, with bromides for cerebral excitation. Locally, instillations of pilocarpine. To increase nerve tone, strychnia hypodermically, electricity, hydrotherapy and ocular douches.

2. *Tobacco Amblyopia.*—Moderate use of tobacco; cigars to be smoked only two-thirds. If well-marked symptoms exist, withdraw tobacco altogether. Stimulate nutition. Inhalations of nitrite of amyl; subcutaneous injections of strychnia; continued currents; ocular douches.

3. *Saturnine Amblyopia.*—Treatment of lead poisoning; sulphur baths, iodide of potassium, purgatives, tonic regimen.

4. *Quinine Amblyopia.*—Purgatives and diuretics, inhalations of nitrite of amyl, injections of strychnia, and electricity.

5. *Antipyrin Amblyopia.*—Withdrawal of the drug has proved sufficient.

6. *Sulphide of Carbon Amblyopia.*—Abandonment of profession. Tonics, iron, quinine, strychnia subcutaneously, inhalations of nitrite of amyl, and electricity.—*Union Med. Mag.*

TURPENTINE AS A GERMICIDE AND ANTISEPTIC.

Although the oil of turpentine (*Oleum Terebinthinæ*, U. S. P.) is not unknown as an antiseptic and germicide, its insolubility in water and its irritating properties have hitherto made its use impracticable. That it has its special uses, however, in this connection, I have had abundant testimony. It is a well-known fact among naturalists that if the air of a cabinet be impregnated with the vapor of turpentine, the specimens are safe from the ravages of moths and other intruders, so long as this condition of the air of the cabinet remains. Having learned the advantage of turpentine in preserving entomological specimens, I concluded to try its germicidal properties in the cases containing surgical instruments. A bacteriological examination of the cases, made four weeks afterward and compared with the examination of cases not provided with turpentine, convinced me of its efficacy, and I soon afterward applied the same principle to drawers containing towels, gauze, bandages, etc. The method is simple. The turpentine is placed in flat large-mouthed bottles at the bottom of each case or drawer, the volatility of the turpentine causing the vapor to impregnate the surrounding air. Of late I have also placed my surgical instruments, the night preceding an operation, in a flat dish containing oil of turpentine. The instruments are completely sterilized, are not injured by

the submersion, and are easily dried by a piece of sterilized gauze or towel. The characteristic odor of turpentine can be removed by ether. The cheapness of turpentine and the ease with which it may always be obtained, added to its special adaptability in preserving the aseptic condition of instruments, bandages, etc., by its vapor, may make it a valuable addition to the list of our antiseptics and germicides. I have also used benzole in the above manner. Its greater volatility gives it a more rapid germicidal action than turpentine, but its great inflammability admonishes caution in its use.—*Medical News.*

THE TREATMENT OF ANTHRAX.

Prof. Kosturin and Dr. Krainski publish in the *Vrach*, in the form of a preliminary note, an account of some experiments they have made on the treatment of Siberian sore or malignant anthrax by means of the toxines of putrefying fluids. They had previously published somewhat similar researches on the effect of certain toxines on tuberculosis, and felt sufficiently encouraged by their results to proceed with the experiments on anthrax. Most of these were carried out on rabbits. The anthrax virus was obtained from a professor of the veterinary institute in the form of a mother culture, from which fresh cultures were obtained as required by sowings on meat-peptone agar, and mixture with sterilized broth, until the latter became quite turbid. About half a cubic centimetre of this injected under a rabbit's skin always caused the animal's death in from thirty-five to fifty-five hours. The substance used as an antagonist to this virus was the extract or broth of fresh meat, allowed to putrefy at a temperature of 16° C. for from fifteen to forty-five days without the free access of air. This putrefying broth when injected under the skin of a healthy rabbit in the proportion of 1–850th of the animal's weight produced a marked rise of temperature, 40.8° C. being the maximum, which lasted for about two days, after which the normal condition was regained. The general result of the experiment was that the injection of putrefying broth five or six hours after the introduction of anthrax virus in all cases retarded death, and in some, especially where the dose of virus had been a small one, and when that of the remedy was repeated two or three times at intervals of a few hours, entirely prevented a fatal result, the animals recovering completely. Two experiments were made with sheep, 0.2 cc. of the culture of the anthrax virus being introduced into each and also into two rabbits for purposes of comparison. Three hours afterwards sheep No. 1 was given 0.5 grm. putrefying infusion of meat a fortnight old, and sheep No. 2 a similar quantity of broth a fortnight old. Rabbit No. 1 was not treated; rabbit No. 2 was given 0.1 grm. of the broth. The results were as follows: rabbit No. 1 died in 60 hours, rabbit No. 2 in 136 hours, and sheep No. 1 in 100 hours, and sheep No. 2 in 66 hours. The necropsy of all the animals showed that they had died from anthrax. The unsatisfactory result here is ascribed by the authors to the very small quantity of putrefying broth injected. In the case of rabbit No. 2 the good effects of the treatment are apparent, but as it was kept in the same hutch as No. 1 it is very probable that it became reinfected. From this and some other experiments it was evident that animals undergoing treatment must be kept in separate cages. It is a pity that further experiments were not made with sheep; still, enough has been done to indicate a possibility of success, especially as the remedy does not appear to be of itself a very serious source of danger. Some attempts were made to test the effects of pure cultures of sarcinæ and of putrefactive bacteria, but entirely negative results were obtained; consequently the authors think that the antagonistic effects of putrefying broth or infusion of meat to anthrax, and perhaps other infectious diseases, do not depend on the bacteria contained in them, but rather in toxins or chemical products of putrefaction. Another important observation was made—viz., that when the putrefaction was allowed to go on with free access of air, the product had little or no power of arresting the progress of anthrax. In order to show the antagonism of putrefaction extracts to anthrax, cultures of the latter were mixed with putrefying broth, and though the anthrax still continued to multiply just as it ordinarily does, injections of this culture were found to be innocuous. The authors are now engaged in testing the effect of putrefaction toxines on the diphtheritic process, and a further paper on the subject may be looked for.—*Lancet.*

MEDICINE.

THE CAUSE OF ANÆMIC HEART-MURMURS.

Anæmic heart-murmurs have been the subject of various ingenious explanations.

The one given by the best text-books for a long time was a morbid condition of the blood, an explanation good as far as it went, but one that did not go very far. Recent investigations make it probable that these murmurs are due to a weakness of the papillary muscles of the heart, by which the curtains of the mitral and tricuspid valves are relaxed and so give rise to an adventitious sound. Experiments show that when in the death of an animal the heart gradually fails, the contraction of the papillary muscles lags more and more behind that of the ventricular wall, and ceases entirely some time before the rest of the heart stops beating. On account of their situation the papillary muscles are the part of the heart wall likely first to feel the effects of a decreased blood supply in anæmia; corroborative evidence of this theory is found in the fact that in acute anæmia and other conditions of sudden and great weakness, a heart-murmur is often to be detected, which disappears, upon compression of the iliac vessels or abdominal aorta, or upon the administration of alcohol or digitalis to strengthen the heart beat.—*Northwestern Lancet.*

HIGH BODILY TEMPERATURES.

In the *Memphis Med. Monthly*, June, 1891, Dr. Jones records the case of a bright girl, æt. 14, primarily affected with tonsillitis, in whom the thermometer at different times registered 97°, 99.5°, 103°, 105°, 109, 112°, 115°, 135°, 150°, 158°. Respiration at no time much accelerated—while the hyprexia lasts there is always nausea and a sense of oppression in the chest.

The circulation is never accelerated beyond 10 or 12 beats to the minute, being usually 85. It has not recently been above 100, nor at any time beyond 120. Patient recovered.

In *The Journal of American Medical Association* Dr. W. J. Galbraith relates the case of a married woman æt. 26, in whom the temperature within a short period registered at different times 95.8°, 107°, 112°, 117°, 125°, 137°, 145°, 151° observed by her physician—while the record of the nurse showed it to have reached 171°. The patient was suffering from peritonitis. Recovering.

Dr. Crofford saw a temperature of 108.5° in a case of sun-stroke. Patient recovered.

Dr. Saunders had seen a temperature of 108° in yellow fever—110° in sun-stroke. Both patients died.

Dr. Williams saw a temperature of 111° in the rectum after death from remittent fever.

Dr. Donkin (*British Med. Journal*, 1889) records an instance of 110°, 112.6°. Once the thermometer rose to 107.2° in right axilla. Five minutes later it was only 98.6°.

Mr. J. W. Peale (*Chir. Trans.*, 1875) reports the case of a young lady having suffered from the fracture of several ribs: two months later the thermometer one day registered 110° and afterwards 122°. Ultimately regained fair health.

Dr. Moxon, (*Guy's Hosp. Reports*, 1879) æt. 22, affected with phthisis, in the ward for ten months. Thermometer rose to 107.4° and one hour later 110.8°, suffering from dyspnœa. Next morning it was 99.8°. On one occasion later it rose to 114° in axilla. Died of lung trouble March, 1880. —*Virginia Medical Monthly.*

THE CARE OF THE CHRONIC INSANE.

In viewing the advantages of the Belgian colony of the insane at Gheel, the question arises, Why should the chronic insane of our country be housed and cared for at a *per capita* cost infinitely in excess of what they have been accustomed to all their lives, and whether, with simpler, plainer homes, familiar occupations and larger freedom, this class would not only be happier, but better off in every way, as well as less expense to the State? Why should the legitimate work of a hospital be hampered, as it undoubtedly is, by the vast accumulation of chronic cases whose care involves an immense amount of work that is non professional? Cannot these cases be just as well cared for in asylums built at less expense, or placed in homes whenever feasible, rather than be permitted to encumber the wards and hinder the work of a hospital in which recent cases demand and should have, every care and all the skill science has at its command? Might there not be greater probabilities in the way of recoveries if this were true?

I simply question, for I know how the life of every hospital physician is burdened with petty details, and how difficult it is under such circumstances to attain to the highest professional ability. For many years the plan for the care of the insane which has recommended itself to me has been that of a hospital to which patients should be committed, and from which they should be drafted, after their condition is determined, into simple, plain, inexpensive cottages or homes, such as the State could best furnish, there to

be cared for well and kindly under medical as well as State supervision, but at a minimum cost, as regards their housing, while in the hospital should be kept those who needed the best of skilled medical care and trained attendance. From this hospital, in all cases where such a course would be advisable, transfer should be made to a convalescent home, and so into the world again.

The mammoth asylums, to which year after year wings are added until no man can have an adequate conception of the needs of his patients, and especially no idea of their pathological condition, are a blot on the intelligence of the age.—*Margaret A. Cleaves, M. D., in the "Journal of Mental Science."*

A CASE OF THE ATAXIC FORM OF ALCOHOLIC PERIPHERAL NEURITIS.

Alcoholic Ataxia :—Ataxic gait; inability to stand with eyes shut; loss of knee jerks; girdle pain; recovery.

T. G., 31, clerk, consulted me on the 2d March, 1889, complaining of pains in the calves of his legs, which were worse on walking about. His illness began on February 18th.

Previous History.—He had never had any serious illness or met with a severe accident, though he had twice fallen from his bicycle and cut his face. Denied having had syphilis or any venereal disease. He had had gout, and used to keep a public house. According to his wife and his employer he had been in the habit of "boosing" himself with beer daily. Took no breakfast, but bread and cheese or ham and a pint of ale at 11 o'clock.

Family History.—His father had gout and died of it. His mother was living, aged 62, in indifferent health; 12 or 14 years ago she was insane. He had one brother and one sister alive and in good health.

History of Present Attack.—His wife and his employer concurred in stating that for about a fortnight they had noticed his memory had failed him. He forgot to do what he was told, and yesterday he imagined he had been at work the day before, although he had not been from home for several days. On Sunday, February 17th, he was in his usual bodily health and took a long walk with a friend. On Monday morning he started to walk to his office and found great difficulty in getting there. The distance was about a mile and the snow was on the ground; but he did not get his feet cold or wet. For the last two days he had had a sense of tightness round the waist (girdle pain.) His wife said he had complained to her of seeing double.

Present Condition.—Patient came stumbling into my room, and very nearly fell; he could not stand steadily with his feet together, and fell as soon as he closed his eyes. The knee jerks were entirely gone. The pupil reflexes and ophthalmoscopic appearance were normal. There were no lightning pains; girdle pain already referred to had been present for two days.

His mental condition was not obviously abnormal, but his wife said that he asked her the same question repeatedly, and she was decidedly of opinion that his mind was affected. There does not seem to have been any moral change. There was no muscular wasting or obvious paralysis. No œdema or eruption on skin. Physical signs normal. Bowels regular.

Urine pale, clear, acid, 1010, contained a trace of albumen, no sugar.

He was ordered hypodermic injections of strychnine, and to become a total abstainer. Owing to difficulties, the strychnine was administered by the mouth and the abstinence maintained till lately, when he had been taking against advice, a little claret.

October 31st.—Patient came to see me again. He could walk quite well; stood quite steadily with his eyes shut and feet together; no girdle pain; knee jerks present. His urine still contained a haze of albumen. The pains in the legs were better.

Remarks.—These cases are sufficiently uncommon to make this typical example worth publishing.

The diagnosis was made on two grounds: 1, the very rapid onset, and 2, the history of alcoholism. It is said that the absence of myosis, of the Argyll-Robertson pupil, of arthropathies, and of visceral crisis are of diagnostic value, but all of these are absent in many cases of typical locomotor ataxia (sclerosis of the postero-external columns.) The loss of memory was another point in favor of alcoholic ataxia, but again, it is not very uncommon to have mental symptoms complicating those cases of locomotor ataxia, which later develop into general paralysis. —*Dr. Robert Saundry, in Birmingham Med. Rev.*

NEURITIS DUE TO POISONING BY ARSENIC.

Dr. E. G. Cutler, in the *Boston Medical and Surgical Journal*, reports a case of neuritis due to poisoning by arsenic. The patient was in the habit of placing in his mouth a number of green paper labels—which were proven by analysis to contain

arsenic—in connection with his employment. The earliest symptoms were numbness and pricking of the fingers, with weakness of the right hand. The weakness in a few days extended to the other limbs, and was accompanied by general soreness and cramps in the calf muscles. The grasp was feeble and the gait shuffling; knee-jerks absent, superficial reflexes weakened; no dyspepsia or urinary trouble; bowels rather constipated; no headache or disturbance of vision. The patient recovered under the administration of iodide of potassium, sponging with salt water, and subsequent daily rubbing with ice.—*Practitioner*, May 1891.

CENTRIFUGAL FORCE IN CLINICAL DIAGNOSIS.

In the *Verein für Innere Medizin* in Berlin on 20th April, Dr. Litten gave an account of a method which had been devised for the adaptation to clinical medicine of the uses of centrifugal force, which has hitherto been applied only by physiologists. The usual methods of filtering, and of allowing fluids to settle, have often certain manifest disadvantages, and these are thus overcome. Special reference is made to examination of the urine, and the ease with which tube-casts, tubercular bacilli and other micro-organisms, blood-corpuscles, &c., may by this means be detected. It is applicable, also, to the investigation of fluid from echinococcus cysts and of pleural effusions. The advantages with regard to the latter are thus stated:

"1. Easier demonstration of tubercular bacilli.

"2. Constant demonstration of blood in clear pleuritic effusions.

"3. Avoidance of the coagulation of the exudation.

"The last is especially important; for, as is known, there are some pleuritic exudations which coagulate immediately, so that microscopic examination of them is impossible. If one warms the glass of the centrifugal machine, and allows the fluid to run into it, and sets it at once in motion, the corpuscular elements are obtained before coagulation occurs."—*Deut. Med. Zeitung*, 4th May, 1891.

SURGERY.

EXTIRPATION OF THE LARYNX.
(LARYNGOTOMY.)

Professor Dr. Tauber, of Warschau, has recently collected all the reliable and available histories of extirpations of the larynx. The number collected from all sources is 163 operations; these Tauber has classified as follows: First, regarding the countries in which they were performed.

In Germany	48	times.
" Russia	20	"
" England	19	"
" Austria	17	"
" Italy	17	"
" France	11	"
" America	11	"
" Switzerland	8	"
" Denmark	8	"
" Belgium	3	"
" Spain	1	time.

Second, when tabulating the cases according to the age of the patient operated upon, Tauber obtains the following figures:

Up to 20 years of age	3	cases.
From 20 to 30	9	"
" 30 to 40	15	"
" 40 to 50	40	"
" 50 to 60	50	"
" 60 to 70	13	"
" 70 to 80	8	"

Third, regarding the results of the operation Tauber tabulates these into four groups.

Group 1. Cases in which the fatal issue was directly due to the operative procedure ("absolutely fatal cases")—67, or 41.1 per cent. of the entire number.

Group 2. This group includes what Tauber terms the "absolutely successful cases," and among these he includes all those who had not suffered a relapse three years after the operation—13, or 7.9 per cent. of all operated upon.

Group 3. This group includes such cases, which although recovering from the operation, suffered a relapse and succumbed inside of a year after the operation; these are called "relatively fatal cases" by Tauber—47, or 28.8 per cent.

Group 4. Herein are finally included such cases which, while recovering from the effects of the operation and remaining without relapse for one year, could not be kept under observation for a sufficiently long period to enable them to be placed with group 2; these Tauber calls "relatively successful cases"—32, or 19.6 per cent.

When the first group is added to the third, and the second group added to the fourth, a very positive but also a very discouraging result will be obtained; the fatal cases mount up to 69.9 per cent. and the successful cases only to 27.5 per cent. In other words, under the most favorable circumstances to

the patient, the operation yields at best only 7.9 per cent of permanent recoveries.

In view of these facts, Tauber is of the opinion that the operation may be ranked with those of which that peerless operator, Stromeyer, has said: "Humanity will lose nothing if such operations fall into disuse, and surgery gains no honor by their performance."—*Deutsche Medizinal-Zeitung*, July 20, 1891.

TREATMENT OF CARBUNCLES BY EXTIRPATION.

Every year a number of lives are sacrificed owing to our faulty means of dealing with carbuncles. When these are treated merely with free incisions, the patient is doomed to a long period of confinement, the skin frequently becomes gangrenous to a large extent, and the final result is at best an unsightly scar. In order to avoid all these unpleasant sequellæ Dr. Riedel, of Jena, reports to the *Deutsche Medicinische Wochenschrift*, the value of a complete extirpation. His opinions as to the value of the procedure are based upon an extensive and most successful application of the method. The operation is conducted as follows: A cruciform incision is made across the seat of the carbuncle, and stretching well into the healthy tissue. The four triangular flaps are then dissected back until the healthy tissue is reached, and the indurated portion extirpated. The usually copious hæmorrhage is controlled by compression. A loose tampon of iodoform gauze is then inserted in the wound, the skin having been brought back into position. The following day the iodoform tampon is removed and an ordinary antiseptic dressing applied. The wound will heal rapidly, and the loss of substance from the center will replace itself very quickly.

The advantages of the method are that by the complete removal of all infiltrated tissue, the dangers of subsequent gangrenous or septic poisoning are completely removed; the scar, also, will be slight compared with that obtained by the method of simple free incisions.

NERVE-COMPRESSION DUE TO CALLUS.

In the *Gazette Hebdomadaire de Médicine et de Chirurgie*, March 14, 1891, there is an exhaustive paper on this subject that contains much of interest by the late Dr. Trelat. Nerve abnormities following fractures are numerous. Sometimes the cause of the fracture is also the origin of the nerve injury. Again, a spicula of broken bone may lacerate or run through a nerve, or the nerve substance may be imprisoned by the reduction of the fracture. All these possibilities are excluded in the present consideration of nerve-compression.

The author cites a case illustrating the good effects of surgical interference, in which there was compression of the radial nerve following the reduction of a fracture of the humerus in a child of eight. After perfect union was established, there remained a paralysis and atrophy of the extensors and an intensely painful spot just underneath and in front of the epicondyle. There was an extensive and deforming callus at the seat of the fracture. Liberation of the nerve resulted in complete use and health of the arm, the child later as a youth winning prizes in athletic sports.

A similar paralysis in a man of forty was treated by the knife, with the result of retarding union of the bone and inducing an abscess at the point of incision. Muscular movements were recovered in time. Paralysis in such cases is not immediate, appearing only one, two or three months after the accident, and progressing slowly as different branches of special nerve-trunks are involved. There is rapid muscular atrophy and sometimes altered sensation. Surgery alone has power to relieve this condition, which in itself is sufficiently serious, the nerve-degeneration being rapid and the compression often setting up an ascending neuritis or myelitis.

Pressure on a nerve may come from underneath as well as from imprisonment, the mass of callus raising and stretching the nerve substance or partially inclosing it in a little channel of osteo-fibrous material or of pure bone. The order of compression depends largely upon the locality of the fracture. In case of pressure from underneath, when the nerve is raised up, instead of being smooth, round, brilliant and glistening, the nerve is flattened, grayish, cloudy and often irregular in outline. When imprisoned by osteo-fibrous material, the nerve may retain its natural rotundity, but has a shrunken appearance within the callus, and presents just beyond it a matty ganglionic swelling analogous to nerve-proliferation in the stump of an amputated limb. The nerve in this instance has the general appearance of a little fibrous cord. The histological manifestation is similar to that resulting from division of a nerve, with this exception: all the fibres in the severed ends of a divided nerve undergo simultaneous degeneration. Not so in degeneration due to this osteo-

fibrous compression. One fibre after another is attacked. There is a difference in time, but not in kind, in these processes.

Age is an important factor in the regeneration of nerve-tissue, the best results in surgery like the foregoing being obtained in young subjects. Crushing the callus is insufficient to afford relief. It is imperative to cut down on the nerve, expose it to view, find out the exact cause of compression, and remove it speedily. The difficulty of the operation—Esmarch's bandage should always be used—is chiefly due to changes in anatomical distribution caused by the callus itself. To avoid bewilderment and loss of time, a long incision should be made and the nerve first traced somewhere in its course where its position is normal, instead of beginning to follow it at or too near the callus. If the nerve is simply lodged under a fibrous cover, the bistoury will serve to liberate it. But if true bone imprisons it, a portion must be chiseled away. The callus must then be leveled and made smooth.

In certain instances it may be necessary to suture the periosteal fibres to prevent future implication of the nerve, or to attach the nerve itself to some neighboring muscle. But such necessities have not yet arisen in the author's practice.—*Jour. Nerv. and Ment. Dis.*

TREATMENT OF CHRONIC INFLAMMATION.

To remove the products of inflammation when occurring in orchitis, epididymitis, the lymphatic glands, or the articulations, Dr. Land (*Revue Internationale de Bibliographie* March 25, 1891) recommends the use of hot compresses, stating that this measure has always given him the best results even when other remedies had proved inefficacious. These compresses should be applied frequently for ten or fifteen minutes several times during the day, taking care, however, that during the applications one compress should not be allowed to remain more than two minutes. The compresses should be immersed with water at a temperature from 104° to 140° F. They should not, however, be used during the acute stages of inflammation.—*Ther. Gaz.*

THE DIAGNOSIS OF FOREIGN BODIES IN THE BRONCHI.

To ascertain which bronchus is the seat of a foreign body is not unusally a matter of difficulty, if we avail ourselves of the assistance afforded by auscultation. If the foreign body exactly fills the lumen of the bronchus, this will be indicated by the absence of respiratory sounds on the corresponding side, while, if the obstruction is incomplete, the sounds will be exaggerated and assume a hissing character. The data furnished by auscultation, however valuable they may prove in the case of a solid body, may leave us in the lurch if we have to deal with a hollow body, such as a bead. This is strikingly illustrated by a case recently reported by Dr. Sprengel, in the *Centralblatt für Chirurgie.* The patient, a child five years old, suffered from severe dyspnœa, resulting from lodgment of a foreign body in the throat. Auscultation revealed normal respiratory sounds on the right side, while on the left they were almost imperceptible. A diagnosis of foreign body in the left bronchus was made and tracheotomy performed; but, after the incision had been enlarged, the bead was seen distinctly lying in the trachea, the lumen of which it filled completely. It was turned with forceps and then ejected by coughing. To explain the auscultatory signs, the author assumes that the bead lay in such a position as to prevent the passage of air into the left bronchus, while admitting it to the right through its aperture. This case is an exceedingly valuable contribution to the literature of foreign bodies in the air passages, since it demonstrates that when a hollow body is lodged at the lower end of the trachea, the physical signs may differ essentially from those produced by a solid body, and may lead us to infer that it is situated in a bronchus.—*Internat. Jour. Surg.*

THE ABORTIVE TREATMENT OF SYPHILIS.

The loathsome nature of pox; the great difficulty and uncertainty of thoroughly eradicating the disease from the system, when once firmly established, has made the dream of its early cure a pleasing one. The abortion of gonorrhœa has received a comparatively greater amount of attention, but when we stop to consider the dangers attending the present methods deemed necessary to effect this purpose, the freedom from systematic infection, and the possibility of bringing about a cure within a reasonably short time by safer means, we realize how much more to be desired would be a sure method of stopping short a syphilitic infection. For two hundred years excision of the chancre has been practised, in the hope, at times apparently realized, that in removing the initial

lesion of the disease the system would escape. Strange as it may seem, after these two hundred years, we cannot yet say just what valuation should be placed upon the method. Some observers have claimed good results, while others have seen only failures follow their efforts. At the International Congress in Berlin, Professor Leloir presented a contribution to the subject, which is of interest as coming from one who has had considerable experience in the matter. As early as 1844 he advised excision: 1. If the chancre is just beginning; 2. if the chancre is so situated that an excision can be removed readily and without danger; 3. if the chancre is not already accompanied by enlarged glands; 4. if it is single, or, at least, easily to be removed in its totality; 5. if the individual is entirely free from such diseases as diabetes, albuminuria, etc. These rules for undertaking the excision were given three years after the author had expressed his belief in the inutility of the operation. His subsequent experience has, however, led him to regard the success of abortive effort as a possibility. He relates a case in which a lesion believed by him to be a true chancre was excised in 1884 (the woman from whom it was contracted being under his care, and surely syphilitic.) The patient was kept under constant observation for about four years without treatment and never showed any further signs of syphilis. Leuger has communicated a similar instance.

Mauriac as early as 1881 expressed his belief in the inutility of this attempted abortion, claiming that excision does not attenuate the near or remote consequences of the intoxication.

Wickham points out quite justly that a well-established true chancre may at times not be followed by secondary and tertiary accidents, or may be accompanied by very discrete lesions only, and hence an error may enter into deductions drawn from the patient's freedom from symptoms after excision. It would, however, not be at all likely that any large number of these mild cases would occur in a given series of excisions.

While it is too much at the present time to claim with Diday that if the excision does not succeed it is because it was not done completely enough, it would still be well for future investigators to make sure that they operate early enough, and include in their cut sufficient surrounding tissue to make it reasonably certain that any outlying cells, bacilli, or virus, which might still be harmful to the system have been removed along with the indurated lesion.—*Med. Record.*

GYNÆCOLOGY.

THE REMOTE EFFECTS OF REMOVAL OF THE ANNEXÆ IN NON-NEOPLASTIC AFFECTIONS OF THE UTERUS.

At the French Surgical Congress Spencer Wells said he concurred in Battey's opinion that, in America, the abuse of öophorectomy, especially in nervous cases, has become really deplorable. He believes with Battey that neoplasms of the uterus, or of its annexæ, often furnish indications for this operation, which non-neoplastic affections rarely do. Oophorectomy, however, may be indicated either by dysmenorrhœa or by ovarian neuralgia which has defied all other treatment and threatens either life or reason. In such cases he has witnessed very gratifying results. But it must not be forgotten that, after removal of the ovaries, menstruation may not be arrested; even menorrhagia may occur and suffering may increase and the general health deteriorate. In a certain, as yet indeterminate, ratio of cases hæmatocele may result or recur. In other cases, the knowledge of their sterility has produced a grave disturbance of the mental balance. He does not share the opinion of certain operators as to the alleged frequency of tubal affections and their incurability without operation. Lawson Tait divides his cases somewhat arbitrarily into three classes: Those in which öophrectomy is done: (1) Because either of some uterine lesion or of the symptoms resulting from it. (2) Because of troubles arising from inflammatory diseases of the annexæ. (3) Because of various nervous disturbances dependent on menstruation. The results obtained in the first category are as follows: Of 274 cases of myomata, 6 were immediately fatal, 8 unsatisfactory, and 257 completely cured—that is, either the symptoms ceased completely, and either the tumor disappeared entirely or ceased growing, or the principal symptom of the disease was completely and definitely relieved. Of this series, to his knowledge, but a single case has been sent to an insane asylum, and this one was evidently insane before the operation. In three other cases mania was completely cured by the physical relief afforded by the operation. A number of cases of eccentricity were likewise relieved. Marked non-development of the uterus associated with normal tubes and ovaries sometimes requires removal of the annexæ for the relief of the intolerable suffering caused by abortive efforts of the uterus to perform its periodical functions.

The results of operation in these cases differ in no wise from those already described. In the second class of cases Mr. Tait has not found time to tabulate his results, and therefore is unable to speak so dogmatically. In this class of cases, however, the underlying conditions are quite different from those of the first class, and the operation itself presents indefinite and indefinable differences of detail. Although often taxing the resources of the surgeon to the utmost, the operation should never be abandoned; contrary to the opinion of many competent surgeons, it may be completed in every case. Mr. Tait is never deterred by fear of rupture, either of the bladder or of the bowel, from breaking up adhesions that may exist between these viscera and an ovary or even a tube. He has seen urinary and intestinal fistulæ form and persist for several months, but has always succeeded in finally curing them. Deep, suppurating sinuses may occur in 5 per cent. of the cases and persist indefinitely; at least until treated by what Mr. Tait calls "circular drainage." The results in these cases, especially in the graver ones, are slower than in myomata, for here Tait reopened the abdomen and found new cysts formed about the stump of the Fallopian tube. These he removed. One of the cases died, but in the others relief was complete and immediate. The remote effects of this operation may be obtained in such cases without arrest of menstruation; and in some of Tait's most successful cases the menstrual period has not been influenced in any way. In 4 or 5 per cent. of the cases belonging to the second category recovery may be delayed by an effusion of blood into the folds of the broad ligament. These effusions have always taken place either during menstruation or during a seeming menstrual molimen. In most cases these effusions are small and disappear rapidly. The remote results in this category differ very little from those in the first category, with one exception, and that of sufficient importance to deserve especial mention. In chronic diseases of the annexæ one of the most distressing symptoms is inability to endure marital relations. In most cases requiring surgical intervention such relations have been suspended for a long period, but may generally be resumed within a few months after removal of the appendages. As to the third series, Mr. Tait confesses that he has hitherto observed what seems to him now excessive prudence. Experience in a few well-marked cases of menstrual epilepsy inclines him to a more favorable opinion than he formerly entertained. He reports his first 2 cases. In both the result was brilliant and permanent. —*Gazette des Hopitaux.*

CURETTING OF THE UTERUS FOR METRORRHAGIA IN A YOUNG GIRL.

Dr. J. J. Conner, in the *Inter. Jour. Surg.*, reaches the following conclusions:

1. I consider curetting of the uterus a safe operative procedure when performed with reasonable care and skill.

2. It is one that may be undertaken with good results by any general practitioner who is competent to attend the ordinary cases of obstretric and gynæcological practice.

3. It will often rapidly cure metrorrhagia when drugs fail.

4. In performing the operation both the dull and sharp instruments are required.

5. Notwithstanding that Emmett says that "the ingenuity of man has never devised an instrument capable of doing more harm," I regard the sharp curette of Sims a useful and necessary instrument, and capable of doing just what it was devised to do, and what no other instrument can do, viz., of shaving off those hard, tough, gristly granulations from the uterine mucous membrane. It was devised by a *surgeon* for the use of *surgeons*, and any one who does not possess sufficient skill should leave it severely alone. True, you cannot *see* it work, but you can *feel* it. Of course, not all cases will need the sharp curette.

6. I would call attention to the youth of this patient, and the entire absence of pain during the whole course of her trouble.

7. I consider this case an example of the triumphs of antiseptic surgery in the hands of a common country practitioner.

OBSTETRICS.

FRACTURES OF THE LEG DURING PARTURITION.

Bergner reports five cases (*Rev. Mens. des Mal. de l'Enf.*, March, 1891,) in children from six months to three years of age, of fracture of the leg occurring during parturition. The fractures were followed by pseudo-arthroses, and the cases were treated by resection. The fracture, which is usually located at the lower half of the tibia and fibula, is caused by traction upon the legs at the time of birth. The mechanism is that of indirect fractures, and the fractures present all the characteristic signs of indirect fract-

ures of the tibia and fibula. The question arises: Why does pseudo-arthrosis instead of consolidation occur in these cases? In the cases under consideration there were no morbid constitutional conditions, hence the cause must be sought in the lesion itself. Of course, defective treatment, or rather an absence of treatment, was primarily at fault, for the children went a long time before it was apparent that any fracture existed. The oblique direction of the fracture, the angle formed by the fragment, and the interposition of the soft parts between the fragments, all are favorable to a pseudo-arthrosis in preference to the customary callus. In all the author's cases there was extreme atrophy of the fragments, which in some of the cases were barely in contact at their smooth ends. If the pseudo-arthrosis had existed some time, the limb would be found entirely atrophied, especially in the segment underlying the pseudo-arthrosis.

The shortening varied from five to fifteen centimetres. The impression of the sole of the foot on the diseased side was narrower than on the healthy side. The author's operation for these cases was an osteotomy. The pseudo-arthrosis was exposed, the fragments resected, and united by suture. An antiseptic dressing was applied and subsequently a plaster of Paris bandage. None of the cases were cured, though the operation was done three times for one of them. These unfavorable results were attributed to the antiseptic method which moderates the inflammatory re-action, and so prevents the formation of a solid callus. The following propositions are offered by the author for future cases: (1) Simple oblique osteotomy or cuneiform osteotomy should be replaced by longitudinal oblique osteotomy or oblique resection of the fragments. (2) Suture and union of the wound by first intention should not be desired, the bones having been brought together and sutured. In this way an intense local reaction will be obtained favorable to the osteoplastic activity of the periosteum. (3) Plaster bandages should be given up. (4) A fracture having been recognized, it should be treated in a proper manner immediately after its occurrence, or as soon afterwards as a diagnosis can be made.—*Archives Pædiatrics.*

PRECIPITATE LABOR.

Dr. P. Strassmann (*Deutsche med. Wochenschrift*, No. 44, 1891) observes that this term has been indifferently applied to rapid labor in the purest physiological sense, and also to cases where the patient, through ignorance, has been suddenly seized with labor pains, and, not knowing their signification, has allowed birth to occur without necessary assistance. Even concealed labor, with criminal intent, has been ranked as "precipitate," and, for obvious reasons, the clinical history of true precipitate labor is of importance in medical jurisprudence. Thus, Dr. Strassmann refers to a case in the Giessen Maternity where a woman was very suddenly delivered without knowing her condition. In a second case, bearing-down pains were taken for a desire to defæcate. The patient therefore sat over a pail, into which the child was born. In a third the patient was asleep until ten minutes before delivery. A precipitate twin-labor is also recorded. As universally admitted, precipitate labor is due either to a large pelvis and readily dilatable soft-parts or to vigorous action of the uterine muscle. The children are, on the average, smaller and lighter than infants born in labor of natural length. Though the maternal pelvis is usually capacious Dr. Strassman has observed one case of precipitate labor where the pelvis was of the flat rickety type. The risk to the child's life is slight, though trifling damage to the cranium is frequent. Fatal hæmorrhage from the cord is rare, in consequence of the low blood pressure in the funis after the establishment of respiration; besides, the cord is often torn through. Ruptured perineum is the commonest injury to the mother in these cases. Flooding after delivery is rare, and in the Giessen Maternity the puerperium was usually normal. There was little or no fever.—*Brit. Med. Jour.*

THE INFLUENCE OF LIGHT UPON PREGNANCY AND UPON THE FŒTUS.

As a result of experiments with mice, Vicarelli (*Annal. di Ostetrica, etc.*, Dec., 1890) found that the absence of light had a tendency to cause early abortion, but did not otherwise modify the course of pregnancy. If the mother was kept in the dark during pregnancy, the development of the offspring was most retarded; the retardation was less decided if, after birth, the offspring were no longer kept in the dark; and least in the case of offspring kept in the dark after birth, the mother having passed pregnancy in the light. The highest degree of development was attained if the mother and the offspring after birth lived in the light.—*Centralbl. f. Gynäkol.*

PÆDIATRICS.

TREATMENT OF ENCEPHALOCELE.

M. A. Broca contributes (*Rev. des Maladies de l' Enfance*, June, 1891) a note on the treatment of encephalocele. He starts with the proposition that patients with encephalocele are doomed to an early death or to become idiots. He utterly condemns treatment by pressure or by puncture and injections of iodine; in those children who escape suppurative meningitis after such treatment the tumor very seldom diminishes, much less disappears. He recommends excision. The base of the tumor is reached by a double incision leaving two small flaps to be used for closing the wound. He condemns incision of the tumor as liable to lead to serious consequences owing to subsequent draining away of cerebro-spinal fluid; he prefers to place a ligature around the base at the deepest point which can be reached. He does not speak decidedly as to the necessity of suturing the periosteum. He thinks that the fear of removing important quantities of the cerebrum may be set aside. The substance of the encephalocele is not often a portion of the cerebrum proper but is a true tumor. In König's case, in which it looked very like a mass of cerebrum, it turned out to be telangiectatic glioma surrounding a very small quantity of cerebral tissue; in Berger's and Perier's cases it was a "cerebroma." In Picque's case, however, though the encephalocele consisted of a cystic dilatation of a portion of the occipital lobe and the cerebellum, the patient recovered, and, in M. Broca's opinion, would have been in a worse case if untreated. Sufficient time has not yet elapsed to permit the formation of a definite opinion as to the subsequent mental development of these children after excision. In Berger's case, in which a cerebroma was removed, the child, at the age of 18 months, appeared to be of "sufficient intelligence. As much cannot be hoped in cases such as Picque's, but the diagnosis of the contents of an encephalocele being impossible it is desirable to operate by excision in all cases. The age at which operation has been performed has varied from a few days to some months, but most of the children less than one month old have died. Strict antiseptic precautions should be observed, several of the deaths having been due to the wound becoming septic.—*Brit. Med. Jour.*

EUCALYPTUS OIL IN THE TREATMENT OF SCARLET FEVER.

The oil of eucalyptus globulus has been used in the treatment of scarlet fever, and favorable reports as to its value have recently appeared in *The Lancet* and elsewhere. A specific action as a curative agent has been claimed for it in some quarters. I would wish to place on brief record my 'own experience with this drug. Amongst a total of 305 cases of scarlet fever dealt with in this Hospital during the year 1890, forty-seven were treated with eucalyptus oil. Forty-four of these cases were consecutive in order of admission, and took the remedy internally (from two minims to five minims, according to age), administered in mucilage and water, every four hours, for periods of two weeks and upwards from the day of admission. In a certain proportion the oil was also used either in spray or as a lotion with water to cases presenting severe throat symptoms; and the lotion form was also employed to irrigate the nostrils and naso pharynx, where the disease had implicated these parts, giving rise to the intractable and deadly "nasal coryza" of scarlatina. In the result there occurred amongst these so-treated cases four deaths, and in no fewer than twenty cases the various complications or sequelæ native to this protean disease arose, including of the severer forms acute nephritis (five cases), multiple pyæmic abscesses (one case), cervical cellulitis (several cases), "rheumatism," pericarditis, and endocarditis. Albumen was found in the urine in sixteen cases. This mortality and complication rate is above rather than below that for all cases during the year. The only definite result noted from its internal administration in these cases was that the mixture caused vomiting in several children. Special stress has been laid upon its efficacy in improving the ulcerated or otherwise diseased throat conditions present in scarlet fever. In these cases it displayed no advantage beyond that due to the lotion form in which it was used, at least equally obtainable from other remedies in use here, and most noteworthy as bearing on this point, are two cases in the series in which, during its use, secondary ulceration, the so-called "diphtheritic ulceration" of scarlet fever, spreading forward from the palatal arches, invaded the hitherto healthy tissues. It was used both in lotion form and mixed with olive oil as a dressing to wounds and abscesses, and in this shape formed a fragrant

and unirritating substitute for carbolic acid. Its efficacy as a deodorant is undoubted. It was not smeared in any greasy preparation over the skin of any of these cases. This is always an unclean and unwholesome proceeding, and should not be adopted.

The conclusion arrived at from a consideration of these cases with regard to the value of eucalyptus oil in the treatment of scarlet fever is that, as a curative agent, it possesses no value, that it neither mitigates the severity nor modifies the course of the disease, that it fails to prevent serious complications and sequelæ arising in due course, and that as an auxiliary to the ordinary methods of treatment it possesses no obvious advantages. Yours faithfully,

DR. C. KNOX BOND, in the *Lancet.*

HYGIENE.

EARLY RECOGNITION OF TURERCULOSIS IN CATTLE.

A most remarkable observation has recently been made by M. Léon Mandereau, of Besançon, which if corroborated must alter very considerably our ideas on the subject of the distribution of the tubercle bacillus in generalized and local tuberculosis. This observer removed from the eyes of cattle that had succumbed to tuberculosis a drop of the aqueous humor, stained it according to Ehrlich's method, and found that the characteristic tubercle bacilli were present sometimes in small, but always in sufficient numbers to be readily identified. This opened up the way for the early diagnosis of tubercle, and M. Mandereau made careful examination of more than a score of animals suffering from tuberculosis in various stages. As he expected, he found the bacillus in the aqueous humor in all cases where the condition was generalized; but, more remarkable still, he found them even in those cases where the disease was confined to the lungs and pleura, and even when it was present only in the liver. This being the case, the diagnosis of tuberculosis could be made comparatively easy during life. This observation is so startling that much hesitation must be felt in accepting it; though made in perfectly good faith, it may be nullified by some undetected fallacy; and until it has been shown that all sources of fallacy were eliminated, it will be well to suspend final judgment. Should it prove to be true, it would be difficult to understand how Cohnheim and Salomonsen's experiments on the production of intra-ocular tuberculosis are to be explained, if tubercle bacilli in the anterior chamber, when introduced naturally along the lymphatics, do not give rise to any marked symptoms of tuberculosis. Of course, here it may be argued that a wound of tissues was produced, and that the conditions are therefore not the same. Another point for consideration is that, if these observations be correct, we shall have to revise all our notions as to the presence of tubercle bacilli in the blood and lymphatics of the system generally, even in cases of localized tuberculosis—conditions in which it has been held that tubercle bacilli were localized not only in their action, but also in their distribution. If the wound theory is to hold good at all, we should expect to find that after puncture of the cornea for the removal of the fluid, the tubercle nodules should make their appearance in the eye; and if these nodules do not occur, it is certainly presumptive evidence that tubercle bacilli are not there. Of course upon such a point as this depends the possibility of the application of the method, even if other observers are able to substantiate M. Mandereau's observations. It is not now necessary to consider this question as regards the human subject, except in those cases of acute general tuberculosis which frequently are indistinguishable from enteric fever or certain forms of pneumonia; in such cases it might be valuable, but to the veterinary surgeons, who in their examination of cattle have to contend with numerous, and up to the present almost insuperable, difficulties, it would be of great value.—*Brit. Med. Jour.*

A SIMPLE REGIMEN IN OBESITY.

The *Journal de la Santé* attributes to a medical officer of the French army the latest "cure" for obesity, which is strangely simple in its carrying out. The form of diet was simply a restriction to one dish at each meal, irrespective of what that dish might be, and no matter whether the quantity consumed was greater or smaller, it was made to satisfy the desire of food to the full at each meal. No supplementary dishes, such as soups, deserts or condiments were allowed; one single dish, and that taken plain, was found to satisfy the appetite much sooner than a variety of dishes, even if the quantity was apparently smaller and on almost an abstemious scale. This regimen was employed also in the case of a lady whose embonpoint threatened too rapid increase, with good results and without any discomfort in the observance of the restrictions. In fact, in one or two instances the reduction of cor-

pulence has seemed to go on rather too rapidly, and it has been deemed best to take means for restoration, in a measure, of that which has been lost. Under this system, as under most others, the excessive imbibition of liquids has to be forbidden, care being taken not to enforce the abstinence from water, especially, to the point where symptoms of circulatory depression arise from insufficiency of volume of blood in the vessels. —*Annals Hygiene.*

MEDICAL CHEMISTRY.

INCOMPATIBILITY OF COCAINE AND BROMIDE OF SODIUM.

In *La Pratique Médicale* for June 19, 1891, it is stated by M. L. Racine that having to prepare a solution of bromide of sodium and hydrochlorate of cocaine, on dissolving these substances in water and mixing them a grumous precipitate was formed, which gradually rose to the surface of the liquid. It seems that this precipitate is actually the cocaine, which is thrown out of solution, and the dangers of such a mixture are self-evident, for the cocaine floating on the top of the mixture would be given in a larger dose than was intended.

PHARMACEUTICAL PROGRESS.

Test Papers.— E. Dieterich made a serious of test papers by impregnating filtering paper with solutions (1:250) of the following salts; Potassium ferrocyanide, this will indicate one part ferric chloride in 25,000 parts of water and one part copper sulphate in 2,000 parts of water; potassium ferri-cyanide, which will indicate one part of ferrous sulphate in 40,000 parts of water; potassium sulphocyanate will react with ferric chloride 1:5000; potassium iodide will indicate lead acetate 1:500, bismuth nitrate 1:7000 and silver nitrate 1:1000; potassium chromate will serve to detect lead acetate 1:2000 and silver nitrate 1:3000; zinc sulphide (made by coatingfiltering paper with freshly precipitated and thoroughly washed zinc sulphide suspended in water,) this will react with solutions containing a copper sulphate 1:15,000, lead acetate 1:15,000, bismuth nitrate 1:7000, silver nitrate 1:8000 and mercuric chloride 1:1200. Starch paper can be made to indicate one part iodine in 25,000 parts water; potassium iodide paper one part chlorine in 30,000 parts water; litmus paper was found to be more delicate and reliable than lacmoid paper.—*Pharm. Centralhalle*, 1891, 314.

NEW ALKALOID FROM SEEDS OF CONIUM.

The highest boiling portions of crude coniine contain a new base, which can be separated by repeated fractional distillations in vacuum and subsequent crystallization. It crystallizes in needles melting at 98°, and dissolves readily in alcohol, ether, and chloroform; it boils at 230°–233°, and has the composition $C_8H_{17}N.O$. It is therefore isometric with conhydrine, and the name *pseudo-conhydrine* has been suggested by Ladenburg, who has examined the alkaloid. —*Chem. Zeitung.*

NEWS AND MISCELLANY.

AMERICAN SURGICAL ASSOCIATION.

Programme of the Annual Meeting to be held in the Main Hall, Grand Army Building, 1412 and 1414 Pennsylvania Avenue, Washington, D. C., September 22, 23, 24, and 25, 1891.

September 22—Tuesday. *Session at* 10 *A. M.*

Roll Call.

President's Address.

Executive Session.

I. Present status of brain surgery. By Dr. D. Hayes Agnew, of Philadelphia. Abstract: Observations and results of Philadelphia surgeons in cases of epilepsy, traumatic and Jacksonian; abscess; hæmorrhage; hydrocephalus; microcephalus; cephalalgia and tumors. Discussion by Mr. John Chiene, of Edinburg, Scotland, Dr. W. W. Keen, of Philadelphia, Pa., Dr. C. B. Nancrede, of Ann Arbor, Mich., Dr. Roswell Park, of Buffalo, N. Y.

II. Report of the Committee on the results which should be considered as satisfactory, of treatment of fractures of the shaft of the femur. By Dr. Stephen Smith, of New York.

Afternoon 3 *o'clock.*

The Association meets with the Congress in the main hall of the Grand Army Building. Subject: Conditions underlying the infection of wounds, including a discussion of disinfection with reference to treatment of wounds; of the relation of bacteria to suppuration; of the resistance of tissues to the multiplication of bacteria; and of the effects of antiseptic agents on wounds.

September 23.—Wednesday. *Session at* 10 *A. M.*

III.—Aseptic and antiseptic details in operative surgery, by Dr. A. G. Gerster, of New York.

Abstract:—1. Personal cleanliness and the cleaning of the field of operation are to be accomplished by mechanical procedures rather than disinfectants; soap and brush *versus* chemicals; brushes hot-beds of infection; their cleansing by boiling.

2. Dressing materials to be sterilized by steam; advantages of this plan.

3. Instruments to be sterilized by boiling in soda solution to prevent rusting.

4. Sponges, their cleansing, preservation, substitutes and use.

5. Technique of operating; advantages of employing few instruments, sponges and assistants; clean dissection, that is, avoidance of tearing and bruising of tissue; careful hæmostasis; no irrigation except where a special indication arises in the shape of existing or accidental contamination by fæces, urine or extraneous filth (as for instance in compound fractures.)

6. Drainage by tubes often unnecessary; its substitutes; where the tubes are indispensable.

7. Dressing, their manner of application and reason of efficiency; *a*, moist; *b*, dry absorbent dressing; *c*, sealing of wound by collodion.

8. In combating septic morbid processes, mechanical measures, such as incision, drainage and irrigating, of more importance than the employment of chemicals.

Discussion to be opened by Dr. Robert F. Weir, of New York, Dr. J. Collins Warren, of Boston, Mass., Dr. J. William White, of Philadelphia, Pa., Dr. Joseph Ransohoff, of Cincinnati, Ohio.

IV.—Surgical treatment of injuries and diseases of the vertebral column, by Dr. J. William White, of Philadelphia, Pa.

Abstract:—*A*. Congenital deformities—spina bifida; review of operative methods.

B. Tuberculosis of the spine. 1. Indications for operative interference. 2. Cases in which the focus of bony disease may be removed. 3. Relief of paralysis in spinal caries after pointing of a psoas or iliac abcess. 4. Paralysis in Pott's disease generally the result of an external pachymeningitis. 5. Pus to be evacuated whenever accessible; treatment by extension process plaster jacket; resection. 6. In caries of portion of the arches with paraplegia, we should almost always operate. 7. Exposure of cord, if bodies of lumbar vertebræ are affected, to relieve pressure and remove diseased bone. 8. Where compression of cord is thought to be due to anterior pachymeningitis, an operation can rarely liberate pressure.

C. Neoplasms. Amenable to operative interference.

D. Traumatism. 1. Some objections urged against operative interference in spinal traumatism unsupported by clinical facts; others largely due to well-founded dread of: *a*. shock; *b*. consecutive inflammation. 2. Recent results of operative interference encouraging. 3. Operation contra-indicated where disorganization of cord is caused by a severe crushing force.

Discussion: Dr. Maurice H. Richardson, of Boston, Mass., Dr. H. H. Mudd, of St. Louis, Mo., Dr. John B. Roberts, of Philadelphia, Pa., Dr. Charles B. Porter, of Boston, Mass., Dr. Robert Abbe, of New York, Dr. W. W. Keen, of Philadelphia.

V. On retro-peritoneal abdominal tumors, and especially those involving the kidney. By Dr. A. Vander Veer, of Albany, N. Y.

Abstract: Tumors—retro-peritoneal in their origion, sources and character; anatomical relations; from retro-peritoneal connective tissue and lymphatic glands; from the supra-renal capsule of the kidney; they may be present anteriorly between the folds of the mesentery or displace the viscera *en masse*, or posteriorly in the dorsal or lumbar regions; they may be benignant or malignant, cystoma, fibroma, myxoma, sarcoma or mixed growths. Gross and minute anatomy. Diagnosis: Difficulties: Indirect by exclusion, from tumors of the viscera, is often impossible. Use of aspirator. Prognosis: Rapid growth is evidence either of primary malignancy or secondary degeneration and infiltration. Operative treatment has not been followed by encouraging results. Treatment: In what cases, if not all, shall operative treatment be undertaken? Difficulties attending the operation. Intimate connection with peritoneum, the viscera and great vessels. Résumé.

Discussion: Mr. Reginald Harrison, of London, England, Dr. Robert Abbe, of New York, Dr. William T. Bull, of New York, Dr. Frederick E. Lange, of New York.

Afternoon, 3 *o'clock.*

The Association meets with the Congress in the Main Hall of the Grand Army Building.

Subject: The late manifestation of syphilis.

September 24—Thursday. *Executive Session at* 10 *A. M.*

VI. Recurrence of cancer of the breast, by Dr. Frederick S. Dennis, of New York.

Abstract:—In a study of the cases of carcinoma of the breast only those cases will be utilized in which a thorough microscopical examination has been made by a well-recog-

nized pathologist; all other cases are to be excluded as worthless. The recurrence of carcinoma in the breast is influenced by: 1. The period of time from first appearance of the growth to the date of the operation. 2. The extent to which infiltration has taken place by any one, or all, of the three well-recognized ways of dissemination. 3. The radical character of the operation itself. 4. The histological character of the carcinoma itself. 5. The appearance simultaneously in both breasts. 6. The personal factors of the individual, such as age, sex, marriage, fecundity, sterility, pregnancy, traumatism, heredity, menstruation, metastasis, mental condition, locality, etc.

Discussion: Mr. Thomas Bryant, of London, England, Dr. Hunter McGuire, of Richmond, Va., Dr. Lewis S. Pilcher, of Brooklyn, N. Y., Dr. D. Hayes Agnew, of Philadelphia., Pa., Dr. L. McLane Tiffany, of Baltimore, Md.

VII. The treatment of tuberculosis of bones and joints by parenchymatous and intra-articular injections, by Dr. Nicholas Senn, of Milwaukee, Wis.

Abstract: Introduction. 1. Tincture of iodine. 2. Carbolic acid. 3. Arsenious acid. 4. Corrosive sublimate. 5. Phosphate of lime. 6. Balsam Peru. 7. Camphorated naphthol. 8. Iodoform; experimental studies; clinical results; immediate and remote dangers; action of on tubercular tissue; indications; technique.

Discussion: Dr. Lewis A. Stimson, of New York, Dr. John Ashhurst, Jr., of Philadelphia, Pa., Dr. Frederick E. Lange, of New York, Dr. A. G. Gerster, of New York, Dr. A. T. Cabot, of Boston, Mass., Dr. D. D. Bramble, of Cincinnati, O.

Afternoon, 3 *o'clock.*

The Association meets with the Congress in the Main Hall of the Grand Army Building.

Subject: Fibroid processes (chronic interstitial inflammation, scleroses); their pathology and etiolygy, with special reference to the influence of diathesis and heredity.

September 25—Friday. *Executive Session at* 10.00 *A. M.*

VII. Treatment of fractures involving the elbow joint. By Dr. Lewis A. Stimson, of New York. *Abstract*: 1. Causes of limitation of motion after recovery; *a*, changes in the relation of the parts of the joint; *b*, overgrowth of bone; *c*, peri-articular. 2. Causes of deformity; treatment; reduction; maintenance—elbow flexed, elbow extended; after treatment.

Discussion: Mr. Arthur Edward Durham, of London, England, Dr. D. Hayes Agnew, of Philadelphia, Pa., Dr. N. P. Danbridge, of Cincinnati, Ohio, Dr. R. A. Kinloch, of Charleston, S. C., Dr. D. W. Yandell, of Louisville, Ky., Dr. Stephen Smith, of New York City, Dr. E. M. Moore, of Rochester, N. Y., Dr. James McCann, of Pittsburg, Pa. In addition to the above the following papers are offered and will be read as opportunity offers at the end of each day's programme:

1. Fractures involving upper third of femur, exclusive of neck, by Dr. Oscar H. Allis, of Philadelphia, Pa.

Abstract: 1. The infrequency renders it improbable that any single observer can speak authoritatively upon the subject. 2. Pathology. A study of the deformity as presented in pathological museums; its uniformity suggests a special agency for its production; an agency suggested at variance with the usually accepted one. 3. Permanent lameness or weakness in the limb not the result of insufficient bone repair; an inquiry into its cause. 4. Deformity in the upper compared with that in the middle and lower thirds. 5. Treatment; inquiry into the defects of prevailing methods; treatment suggested. 6. Faulty professional standard of what constitutes a good cure. 7. Appeal to surgeons for a thorough reopening of this important subject.

2. Thoracic surgery, by Dr. De Forest Willard, of Philadelphia, Pa.

Abstract: 1. Wounds and injuries of thorax. 2. Tumors of the thorax. 3. Conditions of disease. 4. Pus accumulations.

3. A case of diffuse hypertrophy of the breasts, with photographs. By Dr. C. B. Porter, of Boston, Mass.

4. Fractures of the bones which form the elbow-joint and their treatment. By. Dr. Levi C. Lane, of San Francisco, Cal.

5. Old unreduced luxations of elbow. By Dr. Lewis A. Stimson, of New York.

6. The study of a case of hemiplegia with aphasia, following ligature of common carotid artery. By Dr. J. Ewing Mears, of Philadelphia, Pa.

7. Investigation of pistol shot wounds of the skull, and their treatment. By Dr. E. H. Bradford, Boston, Mass.

8. The result of some experiments in the filling of cavities in bones following operations for caries. By Dr. E. H. Bradford, Boston, Mass.

The time for discussion will be limited to ten minutes for each speaker.

Members of the Medical Profession are cordially invited to attend the meetings of the Association, except when it is in executive session.

Clinical Lectures.

VALVULAR DISEASE OF THE HEART.

BY WILLIAM B. CANFIELD, A. M., M. D.,

LECTURER ON CLINICAL MEDICINE AND CHIEF OF CHEST CLINIC, UNIVERSITY OF MARYLAND, BALTIMORE.

A Clinical Lecture Delivered at Bay-View Hospital.

Gentlemen:—I bring before you to-day a number of heart cases, not because I expect to show you anything new in them, but because I wish to illustrate several points of practical importance; these cases are, two of apex systolic murmur, one pre-systolic murmur, one double basic murmur, and one case of tobacco heart. You may notice that I simply designate these as murmurs and I do this purposely, for I wish you particularly to avoid the error of saying after an examination that when you hear a systolic murmur at the apex of the heart you necessarily have a mitral regurgitation. There are other things than the murmur alone to be guided by.

In correctly diagnosing these cases as well as others, I have of course laid great stress on the importance of physical signs found in the chest and a careful study of the normal heart sounds. Knowing the normal heart sounds and the normal areas where these sounds or their abnormal substitutes or murmurs can be heard with the greatest intensity, and applying these two points to a case of supposed valvular disease, it would seem at first sight easy to make a correct diagnosis in every case; but I think you will find in practice that such is not so, that is, if you rely on the chest sounds alone; for example, I think the pulse is one of the most important aids in making a diagnosis of valvular disease, particularly of the aortic orifice. Indeed the pulse is rarely sufficiently appreciated at the present day. In the early days of medicine, writers thought the pulse very important and even Galen has written a long treatise on the subject, and when it was better understood after Harvey's discovery of the circulation, it was still further studied very carefully. But in the more recent times when physical exploration of the chest was taken up, the pulse was neglected, and now it is rarely studied intelligently by physicians.

When you see a case in which you have reason to suspect disease in the chest, feel the pulse, and ofttimes it will tell the whole story, even though a physical examination of the heart show little. We know that arterial tension may point to valvular disease or it may lead to valvular trouble; the tension makes it more difficult for the heart to drive the blood through the vessels and this may give rise to chronic valvulitis, which may result in thickening and contraction of the cusps of the valves with incompetence or stenosis. The loudest cardiac murmurs are those caused by roughening, rigidity or irregularlity of the valve without actual obstruction, and such murmurs are of no importance at first, but later on they may lead to serious trouble. The aortic valve is affected first and the mitral may be affected later on. The pulse tells us the state of affairs most clearly in aortic troubles. In aortic stenosis, for example, the artery is small and full between the beats, but not as a rule very tense, the wave of blood has no forcible blow or ictus, but lifts the finger gradually. In aortic regurgitation the aorta is filled out with blood, but the valves not being competent the column of blood has no support and falls back into the heart, and the pulse collapses at once. This was first described by Corrigan and is called the Corrigan's pulse or water hammer pulse and sometimes the phantom pulse. On inspection pulsation is seen in the carotids and superficial arteries from which a diagnosis may be made. One very good way is to let the patient cross the leg and the pulsation in the popliteal artery will cause a pulsating

movement of the foot. To fully appreciate this pulse you should make the patient raise the arm in order that the effect of the blood against gravity may be observed. A little practice in these cases will enable you to appreciate both the stenotic and regurgitant defects although if we follow these cases to the post-mortem room the two troubles will often be found to be associated. The irregularity of the two radial pulses may cause you in some cases to suspect an aneurism. In mitral disease the pulse is not of so much significance until later on in the disease.

One way to study the pulse is by the use of the sphygmograph, but there are many objections to its use; in the first place it is an expensive instrument and therefore not sufficiently used to be generally understood, again unless one is skilled in its application, it is very misleading, for the tracings may be varied in the same person according to the pressure, and the resulting charts may be a source of error. As I have said above in aortic troubles, it may be of some use, but carefully educate your fingers, always at hand, and you will find that you can often easily dispense with this expensive instrument. In the prosystolic murmur, which is specially noticeable in this case before you, there is usually found a peculiar tremor thrill, or *frêmissement*, first described by Laennec. It may be felt by laying the palm of the hand over the mitral area when its distinct purring sound or thrill is communicated to the hand, felt just before the ventricular systole. This is said to be almost pathognomonic of a presystolic murmur. At any rate it is so often present in this trouble that you should not forget to look for it. It is almost needless to say that the loudest murmurs are often the most unimportant, while the slightest murmurs may be indicative of the most harm. We have all seen cases in which the patient has a murmur like a buzz saw, both audible to himself and all the by-standers, especially when he opens his mouth.

The tobacco heart and the irritable heart may appear unimportant, because we usually hear no heart murmur, but they may give rise to great discomfort and should be treated actively from the start. The Germans lay great stress on percussion of the heart in cardiac hypertrophy, but I must confess I have had little satisfaction from it in most cases. The heart is fixed at its base by the pericardium and great arteries, and when hypertrophy takes place, the apex must of necessity be dislocated. This you may notice in many cases and when you find that the apex beat is more to the left than normal you may look for a hypertrophy. Most of these heart troubles are from endocarditis following rheumatism or from atheroma possibly from some specific trouble.

In the great majority of cases the important etiological factor in acute endocarditis is acute articular rheumatism, and indeed, so often is this the case, as we know, that one of the first questions asked of a patient with valvular trouble, is, if acute rheumatism has ever proceeded this attack of heart disease. But the two important points in the diagnosis between endocarditis from acute rheumatism and endocarditis from atheromatous condition of the arteries is, that in the former the mitral is by preference affected and in patients generally under 40 years of age, whereas in the latter case those over forty are usually affected, and in the aortic valve only, and even if the mitral valve is here involved it is in company with the aortic valve, whereas in acute rheumatism the mitral alone is often affected.

One not uncommon cause of aortic trouble is caused by a sudden over-distension of the heart. Cases have been reported not infrequently of incompetency of the valves from hard work stretching the valves, as well of cases of direct injury from sudden strain. The working classes are particularly prone to this and the men naturally more than the women. In this case the stiffness and incontractibility of the sclerosed vessel offers too much resistance to the column of blood thrown on it during violent exertion and the blood being forced back into the already full left ventricle causes a sudden distension with rupture of the aortic valves.

Valvular murmurs of the right side of the heart are rarely made out. Hæmic murmurs are sometimes heard and occasionally mislead. When the arterial tension is high and a second sound of the heart is sharp and ringing, especially in a patient of full habit, suspect kidney trouble.

Although not exactly belonging to this subject I would add, that these sudden exertions are often the cause of aneurism, for example, the aorta is athromatous and the left ventricle is hypertrophied. In this condition of things a powerful effort of the hypertrophied left ventricle forces the blood through the aortic valves and upon the aorta, causing an aneurism in that part of the aorta which by virtue of its position has the greatest strain brought upon it.

In view of all these facts when a case presents itself to you for diagnosis be slow to make one; in fact never make a diagnosis or

prognosis of heart trouble on a single examination, but rather give the patient some simple remedy and let him return again for a second examination. He may be over-excited and the heart may be acting irregularly and the valves may not close exactly or the cusps of the valves may slide over each other and leave an opening, and this gives rise to a murmur which at a second examination would have disappeared. Of course this is theory but we must think of such theories when we have a case in which a loud murmur is heard at one time and is absent the next. These functional murmurs as they are sometimes called cause much confusion to the physician who bases his diagnosis upon the chest signs alone. Also always examine the superficial blood vessels, look out for superficial pulsation, notice whether the breathing is too frequent and whether there is ansarca or ascites. Again, remember that if there is one thing about which we can learn much in the post-mortem room it is about supposed organic heart disease, for a loud murmur in life may show nothing at the autopsy, while the most diseased heart, after death may have caused no murmur during life.

Unfortunately, or perhaps I may say fortunately, there is not a great deal of scope for treatment of diseases of the heart. In spite of the various substitutes and new remedies nothing seems to take the place of digitalis and even strophanthus, which has just claims for excellence, occupies a second place. In spite of text books and many authorities to the contrary digitalis seems to do good in all the valvular troubles. It not only strengthens the systole and prolongs the diastole but it serves to regulate the heart; theoretically it is contra-indicated in cases where practically it does much good. Cases of tobacco heart improve under lessening of the amount of tobacco used, combined with the use of bromides in large doses, and occasionally digitalis. As it is inexpedient to withdraw tobacco entirely from an inveterate smoker, it is much better to lessen the amount gradually and give directions as to smoking. For example it is better to smoke on a full stomach and cigars are preferable to a pipe or chewing. The pipe is objectionable because the stem collects so quickly the poisonous element of the tobacco which is thus drawn into the lungs in a concentrated form. Smokers are always advised to clean their pipe stems frequently, which they generally fail to do. Such cases are constantly returning for treatment, any amelioration leading to the return of the excessive smoking until the heart is permanently disabled.

When compensation has taken place digitalis should be stopped and iron used. The bowels should always be kept open and if there is the slightest suspicion of dropsical effusion use the compound jalap powder. In plethoric subjects an occasional bleeding does good. Unfortunately cases among the laboring classes too often prove fatal in spite of the best treatment; among the idler and better classes success is more certain, if the diet can be properly regulated and unnecessary excitement banished.

COMMUNICATIONS.

HYPNOTISM AND SUGGESTION IN THERAPEUTICS—TOGETHER WITH CASES AND METHODS EMPLOYED TO CAUSE HYPNOSIS.

BY W. C. DE LANO EASTLAKE, M. D.,

MEMBER OF THE ROYAL ASIATIC SOCIETY OF ENGLAND—JAPAN BRANCH.

It is to be regretted that with the present rapid advance of the medical sciences many therapeutic measures of value should have fallen into disuse, not on account of their inefficiency, but because they savored of quackery. Recently, however, the profession has become broader-minded, and has evinced a willingness to find good wherever it may be found. In the face of this laudable assertion, it must also be confessed that the medical profession at large, is very easily impressed and very prone to fads. It is almost ruinous to the future of any new remedy or method of treatment for it to become a fad. To become a fad does not mean that it is either carefully studied or investigated, but adopted, for the time being, wholesale, and tried upon every unsuspecting patient that comes along. The natural outcome of such a course is disastrous failure in the majority of cases, and the usual result is that the remedy is soon thrown aside and condemned in the same wholesale fashion as it was initially adopted.

Within the past few years hypnotism has been one of the prevailing fads in medicine, and almost every young practitioner has "had it," while—in truth— very few have given it careful, unbiased study. Its unrestricted and unwarranted use by many has been productive of so much harm, that professional as well as public sentiment has

revolted, and it has been largely denounced as quackery. Even at the clinics of our leading medical schools patients have been put through the most uncouth antics while under hypnotic influence. They have been made to commit imaginary murders, suffer all the agonies of fear of detection, thrown into cataleptic conditions, thrust with needles, and burned with imaginary hot irons, and in numerous ways have had almost every nerve in their bodies set on edge, and then racked beyond endurance. It is scarcely to be wondered at that permanent nervous injuries have been known to result from such experiments. The demonstration of hypnotism in medical schools in this country, as a curative or therapeutic agent, has been largely overlooked. Charcot's theory of hypnotism being an artificial neurosis has been generally accepted, and the subject has been treated in the light of an interesting phenomenon. Not long ago Professor H. C. Wood conducted a series of experiments in the Hospital of the University of Pennsylvania, in which, however, he endeavored to show that the suggestions made during hypnosis were not essential to its successful use in therapeutics. The profession in Germany has been prone to regard hypnotism as entirely worthless. In France, and especially at the Nancy School, hypnotism has been given the most careful study, and the most brilliant results have been achieved.

In this country the majority of writers upon the subject agree that susceptibility on the part of the subject is essential to successful hypnotism, but none lay any stress upon the necessity of skill and experience on the part of the operator. Many of my professional brethren will smile dubiously at my assertion that it requires as much skill and experience to become a successful hypnotist as it does to become a successful surgeon. Also, inasmuch as a steady hand and eye, and a highly developed tactile sense go a long way towards making a successful surgeon, just so, a large amount of nervous energy, a keen eye, and a determined will, will go a great way towards making a good hypnotist.

A good reason for doubting the need of skill on the part of the operator, has been the fact—often demonstrated—that hypnosis can be induced by gazing at revolving mirrors or luminous objects. This, however, is poor reasoning. That an amputation might be performed with a buzz-saw should surely not be a just cause for asserting that no skill was needed in surgery.

It is also stated that everyone is not susceptible to hypnotism, indeed that only about one person out of every ten can be hypnotised. Finally, now that the fad is gradually dying out, the profession is becoming content to see hypnotism laid away, agreeing that it is a dangerous toy, capable of much harm, and very little good.

Personally, it must be confessed, I was at first also more impressed with the apparent quackishness of the method than anything else. The memory of Mesmer's wierd sèances, with his expectant patients crowded around his *bacquets*, and he himself, clad in crimson robes, touching one after another with his wand and causing them to fall into the most violent convulsions—all this was far from impressing me favorably with hypnotism. Still, as it was a fad at the time, and as I was largely engaged in literary work, the subject was continually presented to my mind through the channel of articles and monographs, I finally concluded to give it personal study, and began my labors by reading every work and paper on the subject I could find. For the past three years I have continued this work by making a large number of experiments, both alone and also with several colleagues, and in this paper it is my desire to give the reader a brief account of the results obtained.

The points that I wish to call attention to are, first, that in my experiences nearly every person is susceptible to hypnotism; second, that the success of the experiment is dependent far more upon the skill of the operator than the susceptibility of the patient; third, that hypnotism is a valuable and trustworthy therapeutic agent; fourth, that hypnotism can be freely used without occasioning any unpleasant after effects.

These conclusions, it will be seen, are in direct contradiction to much that has been advanced upon the subject, and advanced too, by able investigators. I, therefore, would not venture to give them utterance, could I not substantiate them by the history of cases, and extended personal experience.

My first experiments, in spite of my theoretical knowledge of the subject, were dismal failures. My patient, although very sensitive, sat smilingly opposite to me, while I for a half an hour at a time tried Mesmer's Charcot's, Bernheim's and Björnstrom's methods one after the other, and finally a combination of all. My third experiment was successsul in so far as putting my patient to sleep was concerned. Having accomplished this I was siezed with the horrible fear of my possible inability to arouse the subject, and my efforts in this respect, al-

though successful, were pitiable and frantic, and the nervous injury done was to myself and not to the patient, who took it all as a huge joke.

After this I grew bolder and more self-confident. Experience also gave additional skill, so that now it is a surprise to me if I cannot induce the hypnotic condition in five or ten minutes at the longest, and often can do so in a few seconds, or merely by a word or gesture of command. Again, since I have had the benefit of extended experience, I have been able to hypnotise any subject that *voluntarily submitted* to the experiment. Since the number of my experiments are well up among the hundreds, it surely is evident that the statement advanced as to only one subject out of every ten being sensitive to hypnotism, is incorrect. I have found hypnotism of value in many forms of neuralgia, in nervous dyspepsia, in the vomiting of pregnancy, in confinement, in hysteria, and cases of nervous or mental depression.

Knowing well that the history of cases is tedious reading, I will, therefore, only quote one or two from each class of cases:

CASE 1—FACIAL NEURALGIA.

The patient was a woman, about thirty years old. She had been troubled with facial neuralgia for several months, and had lost much sleep in consequence. Various anti-neuralgic remedies had been tried but all without satisfactory results. The patient was robust, strong, and not in the least sensitive to hypnotism, or nervous in temperament. She had never been hypnotised before. Placing her in an easy chair before me, I was able to induce hypnosis in about three minutes—by my method described further on—and proceeded, by means of suggestions and gentle stroking over the affected nerve, to relieve the neuralgia; and also strongly impressed upon the patient the certainty of a permanent cure. I allowed the patient then to rest awhile, and again repeated the suggestions, after which I woke her up. On opening her eyes she was surprised to find that the pain had vanished, only a slight soreness remaining. The patient slept that night without interruption. A week later, having taken cold, the neuralgia made its appearance again, but the attack was very slight and passed away in a few hours. Since then—and several months have now elapsed—she has been entirely free from the trouble.

I have before me the histories of a score more of cases of neuralgia in which hypnotism was used, and glancing over them I find that in every case relief was afforded, and in about ten per cent. of the cases a permanent and lasting cure was obtained.

CASE 2—NERVOUS DYSPEPSIA.

The patient was a man about forty years old. Thin, and poorly nourished, very nervous and irritable. Constipation and diarrhœa alternating. The least excitement, or business worry would cause severe attacks of indigestion, lasting for three or four days. At other times he would enjoy comparatively good health for perhaps a week. Mentally the patient was very much depressed and inclined to despondency. Hypnotism, coupled with suitable suggestions relieved every unpleasant symptom. The patient's spirits greatly improved, and with them his general condition. The paroxysms of indigestion grew less frequent and finally ceased altogether. The ultimate complete cure was undoubtedly brought about largely by a change of air and scene; but unquestionably hypnotism was an important factor in the treatment. This patient was hypnotised five or six times. No unpleasant after effects resulted from the treatment.

Two other similar cases were also greatly benefited by the treatment.

CASE 3—VOMITING OF PREGNANCY.

This was the only case of the kind that I tried hypnotism in. The case was a stubborn one and had resisted the usual medication. The patient would awake every morning with violent nausea which frequently lasted until afternoon. The patient, a plethoric woman, was hypnotised at night and, the suggestion made that she should awake the next morning without nausea, and should pass the entire day without sickness. The suggestion was followed accurately. The treatment was repeated on the two subsequent evenings. No morning sickness occurred for nearly a week, and then was so slight as to cause no inconvenience.

Regarding the value of hypnotism in confinement, cases have been reported in which the entire course of labor was rendered painless, through suggestion. This result I never attempted to obtain. The three occasions in which I have used hypnotism in confinement, have been in cases in which a severe and unnatural labor was to be expected, and my efforts were principally directed to bring about a natural labor and to lessen the subsequent nervous shock. In this I was successful. One case will elucidate this.

CASE 4—CHILDBIRTH.

Mrs. J.; primapara; twenty-four years

old; very delicate and poorly nourished. The patient's pelvis was very narrow,—I failed to note the exact measurement,—and she had previously miscarried at seven months, and had nearly died during labor. I hypnotised her five times before her confinement, each time suggesting the various stages of a natural and easy labor, and a painless birth; also that she should sustain no nervous shock and should make a rapid recovery. About a week later I was called at 11.30 P. M. and found my patient in labor, if so grave a term can be correctly applied to the small amount of pain she was experiencing. At 4.00 A. M. the cervix was about the size of a dollar, and the patient dozing, the pains scarcely arousing her. At 4.30 A. M. she remarked that she felt something between her legs. I investigated, and found that the head, of what afterwards proved to be a ten pound male infant, had been born painlessly and without her knowledge! I delivered the rest of the child without delay. There was a slight laceration of the cervix. Subsequent recovery was rapid and devoid of any complications. There was absolutely no nervous shock. The two remaining cases of childbirth, in which I had the opportunity of testing the value of hypnotism, were both multiparæ, and had previously had very severe and tedious labors. In both cases hypnotism and suggestion was followed by easy labor and rapid recovery. Of course it is impossible to state how far hypnotism was responsible for the easy labor; at all events the results obtained were greatly appreciated by both mother and physician. These two cases occurred in the practice of a colleague. Regarding the value of hypnotism in various forms of hysteria, a great deal has been written. Indeed, it is in this complaint that the majority of investigators have found use for hypnotism, not so much as a curative agent, however, as a means of scientific experiment. Hysterical patients are all easy victims to hypnotism, and, what is more, are very easily and very often injured by it. So, my experiments in this class of cases was conducted with the utmost caution. At present my experience has been limited to five cases, all either Hospital cases, or occurring in the practice of some colleague. In one case a complete and, so far, permanent cure was effected. This case is of such an interesting nature, attended by so many unusual complications, and was influenced so remarkably by the treatment, that I intend devoting a special article to its consideration. One other case I have lost sight of, and the three remaining cases are still under observation; all are greatly benefited.

I now come to a class of cases in which hypnotism has given me the most remarkable results. The two following cases, taken from a large number of similar ones, are good illustrations.

CASE 5—MENTAL DEPRESSION FROM GRIEF.

The patient was a woman of refinement and culture, about twenty-four years old. A year previously she had lost one of her parents. Shortly after this she became acquainted with a gentleman while at a summer resort, and a mutual (apparently) attachment and subsequent engagement was the result. After her return home she ceased to hear from her "Gay Lothario" and soon learned that he had been engaged to some one else all the while. Her humiliation, grief, and disappointment were bitter and passionate. Nothing seemed to console her, and her condition gradually became one of dull despondency, with almost daily paroxysms of an uncontrollable grief. These attacks were hysterical in character. Her health became seriously impaired, and the symptoms grew more and more alarming.

After a consultation with her family, it was agreed that I should do what I could without her knowledge, as she was averse to any treatment. So, one evening, while paying a social call, I spoke of hypnotism, related some amusing anecdotes, and finally said how, by means of suggestion, I could induce any desired dream. The patient immediately asked to be hypnotised, with the request that I should make her dream that she was with a certain person who was always in her thoughts. I consented, and in a few moments had the patient fast asleep and dead to all sounds but my voice. I then proceeded to suggest that all feelings of love or desire for the man who had deceived her should vanish, never to return; and that these feelings should be replaced by one of aversion and relief to think that her eyes had been opened; that not even a shadow of sentiment or regret should be left; finally that she should grieve no more, but regain her naturally happy disposition. I also suggested that upon waking she should have no recollection of what I had said or suggested, but that she should obey the suggestions, although forgeting them upon waking. I then, after letting her rest undisturbed for a few moments, gently awakened her. My first question was as to her dream. She said that she had had none, that everything had been a blank. She laughed heartily to think she

had been foolish enough to go to sleep, and then the subject was dropped. But the patient seemed uneasy, and finally stepping aside she took a locket from around her neck, and removed from it the picture of the man in question, and unhesitatingly destroyed it, remarking to a friend near her, that she had been a fool ever to give the man a thought. A few minutes later she retired to her room and destroyed the only other photograph she had of the man. From that day to this—over six months ago—she has not given him a thought or sigh. She quickly recovered her natural bouyant spirits and good health. This patient had never been hypnotised previously, and was only hypnotised the once. She was not told the secret of her "cure."

CASE 6—DESPONDENCY AND INCIPIENT MELANCHOLIA CAUSED BY GRIEF.

The patient was a young mother, of about twenty years of age, and of a refined and sensitive disposition, who had been prostrated by the death of her infant, when only eight weeks old. The patient's labor had been most severe and she was in a very poor physical condition at the time of the child's death. She seemed dull and dazed, was greatly troubled with insomnia, and several times a day would give way to violent paroxysms of uncontrollable grief.

In this case it also seemed advisable to keep the patient in ignorance of the treatment. Accordingly, after she had retired and was asleep, I succeeded—by suggestion, in changing the natural sleep into an hypnotic sleep without arousing the patient. The suggestion was then made that her grief should give place to a feeling of peace and thankfulness that her baby was free from suffering. Other suggestions of a reasoning nature were made and then the hypnotic sleep once more changed into natural sleep. On awakening the next morning, her first words to her husband were, "I can't grieve for baby any more; think only how he might have suffered had he lived!" And so her grief faded away. True, she cannot speak of her infant now without the tears coming to her eyes, but she always adds, "It was for the best, and I'm glad my baby is safe." With due care her health improved and she is now well and contented.

I have the histories of several others of mental depression from various causes, in all of which hypnotism was used with signal success, and without producing any unpleasant symptoms. Surely this field of research deserves more than the mere passing glance it has thus far received from the profession.

METHOD OF PRODUCING HYPNOSIS.

I have reserved a description of my method of inducing, or rather producing hypnosis, for the second part of this article, in the hopes that the histories of a few successful cases would awaken sufficient interest in the reader to cause him to peruse carefully a description that might otherwise seem very prosy; but in which, however, every detail is of the utmost importance to the success of the treatment.

After making a careful examination of the patient and obtaining a history of his case from his own lips—and we will assume that the case under discussion is that of a man, the English language lacking an impersonal pronoun as yet—I also am careful to note his temperament, to find out whether he is skeptical, or believing, nervous or self-possessed. The value of this "sizing-up" of the patient will be apparent to the reader later on. In my conversation, I endeavor to impress him with my self-confidence, and speak with considerable positiveness as to the success of the treatment, but only as far as my being able to hypnotise him is concerned. I then seat the patient in an easy chair, the back of which is sufficiently high to serve as a head-rest, and the form of which is such as to permit him to recline at perfect ease. The arm-chair found in nearly every drawing room answers admirably, but a luxuriously upholstered, deep-seated club chair is the best, it seeming to be especially designed for a quiet nap. In such a chair I ask the patient to make himself thoroughly comfortable, resting his hands upon his knees, and his head resting against the back, which I make more comfortable with a small cushion if necessary. I have the chair so placed that the patient faces the light—either the full light of day, or a strong gas or lamp light. I then seat myself before him on a somewhat higher chair, but so as not to hide the light from his face, and move up close to him, so that I can grasp his hands, as they lie upon his knees, without his extending his arms. My eyes being on a higher level than his, he is compelled to look up, when looking into mine, and this in the face of a strong light; while I am looking restfully downwards with the light over my shoulders. I then take his hands in mine, with a firm, strong grasp, without squeezing, taking care not to extend his arms or to disturb his comfortable position in any way. I then proceed to talk to him

on any subject that I think will arouse his interest and allay any existing nervousness or fear. I endeavor to gain his confidence and interest, and at the same time to quiet him, and induce what might be termed a receptive condition. This I do without looking at the patient. This is all designed to make your patient absolutely submissive. Experience soon teaches you when you have proceeded far enough; and when you have a comfortable, interested and submissive patient before you, the success of the experiment is well-nigh assured. It ought not to take longer than five minutes to induce such a condition. Then ask him to endeavor to follow each suggestion you make, being careful to analyze his feelings before answering. Now raise your eyes to his, and ask him to look intently into either one of your eyes, and not to let his glance waver or change from one eye to the other. Return his look with a fixed stare, which should be maintained for some time without speaking. The voice of the operator during the entire course of the experiment should be well modulated, confident, measured and determined; it should bear in it the ring of absolute certainty. This is absolutely essential. To say, "Don't your eyes feel heavy?" will probably have no effect; but the remark, "Your eyes *are* heavy," made with positiveness will really make the patient's eyes heavy.

Now regarding the gaze with which you transfix your patient. Every physician has had occasion to witness that uncanny, vacant stare of patients in delirium, or maniacs—a stare which seems to look through you instead of at you, and which, at best, is an unpleasant thing to see. This pleasing expression of countenance can be acquired without necessarily becoming either delirious or insane. A similar look may be seen in persons who are "day-dreaming," or in a "brown-study." It may be acquired by trying to look into, or through anything instead of at it. That is, try to look deep into your patient's eye instead of at it, just as you would stand at the open door of a dark room and try to gaze within. I acquired the stare by assiduous practice before a mirror, and when, to all appearances, I was a fit subject for an asylum, I felt sure that I had the right stare.

This gaze is undoubtedly the most important factor in rapid hypnotisation. It holds your patient spell-bound, robs him of power to move hand or foot, tires his own gaze in an incredibly short time, and fascinates him. I have never known it fail to impress even the most stubborn and defiant subjects. Now, while still keeping your piercing gaze upon the patient, almost imperceptibly increase the pressure on the patient's hands, and in a short time you will feel a slight, and gradually increasing, tingling sensation in your hands and wrists, and are safe in suggesting a similar sensation to the patient, in some such words, "you feel a tingling, pricking sensation in your hands, as though you were holding the poles of a weak electric battery." When your patient assents, add, "You see, I can induce any sensation I desire." When the subject realizes—or thinks he realizes—that you, by your hypnotic power, have induced this sensation, the impression is very decided. Presently, the fixidity of the patient's gaze—which you must see is maintained—will begin to tire his eyes. Do not let him see you wink, that is wink only when he momentarily closes his eyes, and he will not know you have done so. Presently you will experience the well-known optical delusion, caused by the steadiness of your gaze, of seeing your patient's face change color and part of it become invisible. Considering that your eyes are not undergoing the strain that the patient's eyes are—he facing the light—you may safely assume that he is experiencing the same optical delusions. Therefore suggest them to him; cautiously, however, waiting for a look, gesture, or expression of assent before proceeding each step. Finally, you can tell him that your entire face will gradually disappear until he can only see the eye he is gazing at. You can now increase this impression by aid of this delusion, and make yourself disappear and reappear apparently at will. To disappear all that is necessary is to remain unmoved, until by your patient's expression you can tell that his vision is blurred. To re-appear, simply move your head ever so slightly forwards; this will change the range of vision sufficiently to rest the patient's eyes somewhat, and your face will become clear again. Now, ask the patient not to speak again, but to keep his gaze still fixed on your eye. Presently his eyes will begin to water, and you can inform him that they burn and are growing heavy, that he can scarcely keep them open, that they are closing, etc., until, sure enough they are closed. Do not, however, imagine your patient asleep, but proceed with your suggestions.

Tell him his eyelids are growing very heavy, that there is a general disinclination to move, that his breath is growing deeper and deeper,

that there is a comfortable feeling of warmth about his body, that your voice sounds farther away (soften it at this junction,) that his arms are getting heavier, and his limbs feel numb, and so on.

Note carefully the response to each suggestion. You will probably see an expression of sleepy content go over the patient's face, his breath becomes deeper and more regular, and his hands are heavy in yours.

Now tell him that he is gradually going to sleep, that he feels comfortable and contented; then add in a firm, commanding voice "you *can't* open your eyes, they are tightly closed; you *can't* open them!" The patient struggles to do so, but in vain. Then slowly release your grasp on his hands, lay them on his knees and stroke them gently but firmly, saying, "your hands are getting heavier and heavier, they feel like lead, you *can't* move them!" Again your patient will make an effort to raise his hands, but they seem glued to his knees. Follow these commands by telling the patient that he is fast asleep, and usually his head will drop to one side, and you will unmistakably see that he is fast asleep, and yet alert to every word you may say. He is now a tool in your hands and ready to receive any suggestion you may give utterance to, but his nerves are also in an exquisitely sensitive condition and easily shocked or injured. The harm in hypnotism is done by putting patients' while in this condition through a series of trying antics. By making the patient open his eyes, the operator can induce the sonambulistic stage of hypnotism; but for therapeutic purposes I have never found this necessary.

As to the nature of the suggestions they are, of course, entirely dependent upon the malady of the patient.

Say, for example, that the case is one of facial neuralgia, the suggestions would be somewhat as follows: "The pain in your face is growing less;"—accompanying this with a gentle stroking over the painful nerve —"now it is quite gone. My touch has made it vanish, and now all soreness is leaving your face; now it also is gone. You will sleep well to-night free from pain, and you will awake to-morrow morning free from pain. When I wake you up all pain and soreness will have completely disappeared. It *cannot* pain you; and the pain will stay away; it *cannot* return," etc. Make each suggestion plain, positive and commanding. Let there be no doubt or wavering in your voice, but speak in a slow tone of positive assurance, and let each word have its effect. It is well to intensify the impression by a repitition of the suggestions once or twice before waking the patient.

Before finally waking the patient let him rest quietly for a few moments, after having impressed upon him that, besides a freedom from pain he is to feel no ill effects from the treatment but to wake up refreshed as from a natural sleep.

To awaken your patient, merely tell him to wake up, without raising your voice. Clap your hands lightly as you do so.

As long as it takes to describe my method —which by the way is somewhat similar to that employed by Bernheim— the whole procedure rarely takes more than fifteen minutes, and is frequently accomplished in less than ten.

I have frequently been able to put sensitive subjects to sleep by a mere word, and always proceed rapidly or cautiously according to the temperament of the patient. However, I have always found it best to proceed gradually, and not to surprise the patient into a sudden hypnosis, although this is frequently possible.

I remember one instance in particular. I had been listening to the conversation of a few chance acquaintances, in a business office of a friend, and hypnotism was under discussion. One of the group—a strong, energetic man, of about forty—was particularly vehement in his denunciation of hypnotism as fraud and trickery. "Why," I said, laughingly, "you don't know what you are talking about. I could make you fall down in one moment, if I wished to!" "That's a lie!" was the quick and rather uncalled for response. Nettled at the taunt, I sprang to my feet, fixed my gaze upon his eyes, and with a commanding gesture exclaimed, "You are falling now, your knees are giving away under you! *Down* you go!" And down he went, sure enough, to the floor. I assisted him to rise, and he got up, pale, trembling violently, and a firm believer in hypnotism.

Such, briefly, is the method that has yielded me the results shown in the cases cited. Far be it from me to claim for hypnotism any undue merit or virtue. It has been merely my desire to point out its sphere of usefulness, and to endeavor to obtain for it an acknowledged place in therapeutics. I am glad hypnotism is not the fad it was last year or the year before, and should be the first to decry its general adoption as a "cure-all." I am, however, equally averse to the idea that so valuable a therapeutic agent should be relegated to the level of such

quackish methods as "Magnetic Healing," "Christian Science," and the like. Hypnotism has a place in therapeutics as legitimate as electricity, massage, or rest-cure.

Finally, I would caution all investigators of the subject not to be chagrined at frequent failures at the outset. The successful practice of hypnotism demands assiduous practice, long experience, and a certain degree of aptitude on the part of the operator. Let us hope that the mind of the profession may not be blinded to any good, surrounded though it may be, by mysticisms and the vagaries of charlatans.

118 East Walnut Lane, Germantown, Pa.

SOME OF THE RECTAL MALFORMATIONS AND DISEASES OF INFANCY.[1]

BY R. H. WORTHINGTON, M. D.,

DENVER, COLORADO.

Imperforate anus is a malformation fortunately of comparatively rare occurrence. It is due to arrest of development in fœtal life, the intestine being derived from the inner, while the anus comes from the outer layer of the blastodermic membrane and a failure of the two to unite brings about this condition.

There are several varieties of this obstruction.

1. The anus may be perfectly formed and joined to the rectum, which is simply occluded by a membrane.

2. The anus may be perfectly formed and the anal opening be apparently normal, but it terminates in a blind pouch as does the rectum, and the two may be slightly or widely separated as the case may be.

3. In this form there is no trace of an anus, the rectum terminating in a blind pouch as in the second form at a variable distance from the skin.

4. The rectum may open into some part of the genito-urinary tract—the bladder, urethra or vagina—the last two being more common.

When the opening is in the vagina it is usually better to postpone operating for a few weeks or months as the child's life is not in immediate danger as long as there is a sufficiently large opening to permit of evacuation. As soon, however, as the child is sufficiently strong to bear an operation, an attempt should be made to form an anal opening by cutting down on to the end of a bent probe inserted at the vaginal orifice. The mucous membrane should be brought down and stitched to the skin and the anus kept patent by the daily passage of a small bougie or the mother's finger. If this can be done, the recto-vaginal fistula will usually close in a short time without suturing, though this may be necessary later.

In all cases where an evacution is impossible an immediate operation is indicated and not a day should be lost as the abdomen will only become more and more distended and the difficulty and danger much increased by delay. A careful dissection should be made from the natural site of the anus. The incision should be in the median line upwards and backwards, keeping close to the sacrum. But little if any chloroform should be given, so that any bulging downwards of the rectal pouch may be felt when the child cries. The pelvic diameters in the new born infant are little more than an inch in either direction, so that there is but little room to work in, and unless the gut is found within an inch of the surface, it is usually necessary to remove the coccyx to get more room. A probe or sound in the urethra in the male or in the vagina in the female is a valuable assistance. When the rectum is reached it is important that the gut should be brought down and stitched to the skin if possible, as there is a great tendency to contraction and in any case, it is difficult to keep the anus open. Dilatation by the finger or by bougies must be kept up till the tendency to contraction ceases.

It is impossible to condemn too strongly the practice of puncturing with a trocar in the hope of striking meconium. Mr. Harrison Cripps has tabulated 100 cases treated in various ways, 17 of these cases were treated by puncture, and of these 14 died, and only 3 recovered—a mortality of 82.3 per cent, while of 39 cases treated by perineal incision or dissection 14 died and 25 recovered—a mortality of 35.9 per cent. The dangers of puncture are that there is a great likelihood that either the bladder or the peritoneum will be injured and the rectal pouch will not be found, and if it is found it is almost impossible to keep the opening from contracting, and the child dies later from obstruction.

Should the bowel not be reached by the perineum, colotomy should be done at once. The inguinal operation being preferable unless the abdomen is very much distended, in

[1] Read before the Denver Medical Association and Arapahœ County Medical Society.

which case we are forced to the Lumbar opening.

Cripp says: "Owing to the great improvement in the method of operating, the mortality from inguinal colotomy has now been reduced to less than 5 per cent."

While in New York this year I had the opportunity of seeing two cases of imperforate anus in the service of Dr. Kelsey at the Post Graduate Hospital. In one case the child was in a very low state when Dr. Kilsey did an inguinal colotomy. This was several weeks before my visit. When I saw it the child was well and fat. There was a small anal pouch, and on the introduction of one little finger into it, and the other into the lower opening of the colon, I could plainly feel that the two were separated by an apparently dense fibrous mass for at least an inch and a half. In this case it would have been impossible to keep open any canal that might have been made by operation from the rectal to the anal pouch. The other case I saw Dr. Kelsey operate upon, the anal pouch was about ½ to ¾ of an inch deep. The physician who had attended the mother had punctured with a trocar but had failed to reach meconium. Fortunately he did not set up peritonitis. When the child cried a bulging could be felt in the anus, and on carefully incising in the median line meconium was reached at a depth of about half an inch beyond the anal pouch. Dr. Kelsey was doubtful whether it would be possible to keep the rectum open without stricture occurring. The child was doing well when I left. It was operated upon on the 7th day and the abdomen was so distended that inguinal colotomy would have been very difficult.

Closely connected with this subject is that of Congenital Contraction or Stricture. This may be a case which has just escaped being one of imperforate anus of the first form I mentioned, in which a semicircular or annular band encircles the bowel feeling as if a cord were tied around it. More commonly it is a congenital narrowing of the anal orifice, which passes without notice until the child is old enough to have solid motions. It is then found to be constipated and has to strain very hard to have a passage at all. Insufficient attention has been paid to this condition, which, though not very common, is I believe, frequently enough the cause of infantile constipation to put us on our guard. I would suggest that it is well to examine the anus in all troublesome cases of constipation in children, and, if the finger will not enter easily, advise the mother to insert her finger daily, well anointed and very gently.

I have seen several cases of constipation in the adult in which the anus was no bigger than in a two year old child, which were relieved by dilatation, and I believe that the condition was congenital with them. In one case there was an internal procidentia or partial intussus-ception, which I have little doubt was caused by the straining necessitated by the infantile anus.

Procidentia in children is by no means uncommon and when it occurs the bowel should be carefully examined. If there is a history of bleeding from the anus a polypus will usually be present and should be searched for in every case. If found and removed there will seldom be much difficulty in curing the procidentia. Ascarides are another common cause. Where there is no local lesion procidentia will usually be found to be due to the pernicious practice many mothers and nurses employ by placing a child on a vessel and making it sit there and strain till it has a passage. When a child is constipated and of rather lax fibre this is quite enough to bring the bowel down in course of time. Children strain more than adults anyhow and in them the straighter curve of the sacrum predisposes to prolapse.

The treatment consists in first washing the prolapse bowel well with cold water and alum and water, or any other astringent, and after greasing it well, returning it by gentle taxis. If there is difficulty in doing this Dr. J. C. Davis' method will usually succeed. He places a handkerchief over the prolapse gut and pokes the finger into the end covered with the handkerchief returning first the part that came out last. The finger carries the handkerchief which in its turn carries the gut in and allows the finger to be withdrawn to poke in more handkerchief and gut till it is all reduced. The handkerchief can then be withdrawn by gentle jerks by one hand while the fingers of the other against the anus prevent the gut escaping. A small pad of cotton against the anus with a strip of adhesive plaster drawing the buttocks tightly together prevents the immediate re-occurrence of the prolapse. Care must then be taken that the bowels are kept moderately loose and that the child *always has* its passage either lying down or standing up, never being allowed to squat and strain. While the bowels are moving the mother or nurse should draw one buttock away from the anus. This is a great help in preventing further prolapse. These

precautions must be persevered with for several months till the tendency disappears. If the bowel cannot be kept up in this way the application of fuming nitric acid or linear cauterization may be necessary to effect a cure, but the milder measures are usually sufficient with the efficient co-operation of the mother.

THE FŒTAL HEART SOUNDS DURING PREGNANCY AND LABOR.[1]

BY A. W. HENCKELL, M. D.,
ROCHESTER, N. Y.

Percy called the attention of the profession, about 1818, to this valuable sign in midwifery and legal medicine, by stating that it was possible to determine whether the child be living or not. This subject is usually lightly regarded alike by student as well as medical practitioner, possibly because American obstetricians have given so little attention to this valuable aid in diagnosing pregnancy, or determining whether the child be still alive. European teachers and writers, on the other hand, lay great stress upon the value of fœtal heart sounds and call attention to the importance of such who wish to practice the obstetric art successfully. During pregnancy its chief value lies in the fact that it is one of the *sure* signs to establish the existence of this condition. Once the fœtal heart sounds are heard all doubts are at an end. It is also of value to corroborate other symptoms already diagnosed. The non-detection of the heart's pulsations would not justify a diagnostician in stating that no pregnancy existed. During the stages of labor it is of more *direct* value to life, as it is here that it guides the accoucheur in the selection of his operative procedure, particularly so in the application of forceps. Cæsarian section and even in exceptional cases of mal-presentation requiring version. The student, and the medical practitioner who has never looked or endeavored to find these sounds, can best practice by listening to the chest of the new-born, for here an opportunity is presented much oftener than in the lying-in chamber. The heart sounds can rarely be heard before the sixth month (occasionally at the twentieth week) and in normal presentations are best heard along a line drawn from the anterior superior spinous process to the umbilicus. They are clear, distinct, double pulsations following each other in rapid succession, varying from 120 to 140 beats per minute. The first sound is usually shorter and feebler than the second, which is loud and clear and which is the one usually heard in ordinary auscultating, and heard over the body of the child. If the fœtus lie close to the uterine wall it can best be heard over its dorsal aspect or on the chest, in face presentations. This necessarily varies with the thickness of abdominal walls and the amount of amniotic fluid. When the child's back is turned posteriorly it may not be heard at all. The only signs with which they could be confounded are the placental (or uterine) bruit and funic souffle. While it is true that the latter can be easily excluded on the ground of its infrequent occurrence, yet it is necessary to bear it in mind while listening, and can be differentiated by its faint buzzing sound. The only other important sound then, is the uterine souffle; and no difficulty will present itself even to the inexperienced, to distinguish it from or mistake it for the fœtal sounds, as the blowing sound of the uterine suffle is synchronous with the maternal impulse. The indications of danger to the child are: (1) Feebleness; (2) excessive frequency, and (3) irregularity in rhythm of sound. The sounds usually grow less or disappear during a contraction, but should be heard *immediately* after the pain. The position of the child may also be determined by giving attention to the point where the sounds are *best* made out. Another, but trivial consideration, is the determination of the sex of the fœtus before delivery, as in most cases of male children the pulsations vary from 120 to 125, and in the case of females from 140 to 145. When the number of pulsations is between 125 and 140 it is impossible to state, as this is not an infallible sign.

I am certain that I have been able to save the lives of several children owing to my observing the signs under consideration, and as a result these cases were not added to the already large number of "still-births," about as convenient a term in midwifery as "malaria" in general medicine. In the operations necessitated by deformed pelvis, it becomes of momentous importance to the obstetricians as to the course they aim to in justice to both mother and child. Medical men, particularly such as are called upon to wait upon women anxious for a living child, will readily value a sign which will

[1] Read before the Monroe County Medical Society, May, 1891.

enable them to achieve this object in a great majority of cases.

REPORT OF A CASE OF ABDOMINAL UTERINE TUMOR.

BY EDWARD BORCK, A. M., M. D.,
N. ST. LOUIS, MO.

HISTORY:—Mrs. C. N., a farmer's wife from Kansas, was sent to me by her family physician in May, 1885; she was 41 years of age, five feet six inches high, natural weight 96 pounds, brown hair mixed with gray, blue eyes, had always been in pretty good health, quiet temperament, menstruation regular, of late some leucorrhœa, a small tumor in pelvic cavity of about two years growth.

DIAGNOSIS:—Fibroid of the uterus. Ovaries not implicated.

Refused to operate, advised the patient to go home and wait until her climateric period had passed; if by that time the tumor had not increased very much, and she would be well otherwise, then the tumor would very likely cease growing, or even atrophy after she had passed the critical period, and need no interference. If however, the tumor should become larger, to return and we would see what would be best to be done.

May 15th, 1891, six years later, Mrs. C. N. arrived again at my Private Surgical Home. She came determined to have the tumor removed and get well; she could not stand it any longer, something must be done for her as the tumor had increased in size considerably. Menstruation had ceased for some time.

EXAMINATION.—Patient's weight 121 pounds, circumference over umbilicus 48 inches. Otherwise the patient was in a very good condition, excellent spirits, tranquil, and not the least afraid.

DIAGNOSIS BEFORE OPERATION.—Fibro-cystic tumor of the uterus, left ovary not involved, right ovary may be cystic degenerated, no adhesions except to pedicle. Taking all the circumstances into consideration I advised the operation.

May 17th at bed time she took calomel gr. x, followed the next morning with a Seidlitz powder.

May 18th before retiring a warm bath.

May 19th, in the morning a cup of milk and a slice of bread; a copious enemeta of warm soap water, which cleaned the bowels thoroughly; a vaginal douche of warm water was given, and she was put to bed. At 11 o'clock morphine sulph. gr. ss, and warm water bottles to limbs and body to keep her moist while she slept. At 12 o'clock she took the chloroform with ease. I operated in my usual manner, Drs. Wm. H. Graves and Henry Summa assisting; present, Dr. L. W. Gerling, Mr. Heideman, M. S., and Miss Henriette A. Stoffregen, the nurse.

After opening the abdomen by an incision extending from the pubis to about 1½ inch beyond the umbilicus, a large round solid tumor was exposed; no adhesions anywhere; the ovaries not involved though both degenerated. On the right side of the tumor were several small bunches or protrusions from the tumor and more soft or cystic like; and closely surrounding the right ovary. The elongated uterus formed the pedicle proper, the fundus was involved in the tumor.

I ligated both ovaries with a single silk ligature, separated the peritoneal covering all around bringing into view the pedicle proper, introduced through the uterine pedicle one of my cyst elevators (double needle), tied a strong silk ligature below the needle and around the pedicle; amputated ovaries and tumor with a pair of serated scissors, stopped all hæmorrhage thoroughly, which was very little; she lost in all not over one ounce of blood. The abdominal cavity was cleansed and flushed with the artificial serum. I then touched or amalgamated all the blood vessels with the actual cautery, and stitched the two peritoneal folds together with interrupted fine silk ligature, covering and inclosing the pedicles; again flushed the cavity with warm artificial serum, and closed the abdominal wound with deep seated and superficial silk ligatures, those obtaining a clean shut peritoneal pack. Dressed abdomen in the usual manner. The patient rallied well.

PROGRESS OF THE CASE.—In the evening after the operation her temperature was one degree below normal, pulse weak but regular, respiration slow. She had been a little nauseated for a few hours but had suffered hardly any pain and slept at intervals.

MAY 20TH, MORNING.—Temperature 100⅖, pulse 90, respiration 24. Some accumulation of gas in the intestine. A glycerine rectal suppository relieved her almost immediately.

EVENING.—Temperature normal, pulse 72, respiration 18. Otherwise in good condition and spirits. From this time on she kept at this stage and slowly improved.

Evacuation of bladder and bowels natural.

On the third day, May 22nd, I removed every other deep seated ligature: the wound was closed and perfectly dry. By the seventh day all the ligatures were out, not a drop or sign of any pus, patient was up. On the 14th day the patient walked out to the dining room and took her meal with the family. For the first two days after the operation she was fed on oatmeal gruel, beef tea, brandy, ice, according to circumstances. After that milk, meat, eggs, vegetables, etc. in addition.

The tumor weighed twenty pounds and seven ounces. I presented it to the St. Louis Medical Society with a short history on the evening of the 23rd of May and made a section of the tumor in the presence of the members, and would say that to all appearance the mass was calloid, showing beautifully the uterine tissue, that is the upper part of the fundus of the uterus, from where the growth originated with both degenerated ovaries attached.

General remarks:—It will be observed that I took all possible aseptic precautions. Nothing but clean distilled warm and cold water was used, and the artificial serum for the abdominal cavity, instruments, and ligatures. In my early operations I followed a strict antiseptic plan, carbolic acid spray, etc., etc. In time I have learned better and instead prefer the aseptic method, cleanliness and discipline. No opium, no medicine of any kind was used, nor was it needed in this case. This patient was an admirable patient, quiet, obedient, good spirits with faith in her recovery. I am especially pleased that she took my advice in 1885.

This is my 69th case of ovarian or uterine tumor operated upon, exclusive of all other laporatomics for other causes. Out of my first 25 cases I lost four patients: out of the next 25 cases I lost but one patient. See report in September, 1885.

Remarks on Abdominal Surgery with 50 Cases.—Read before the Mississippi Valley Medical Society, Evansville, Ind., September, 1885. In full in the *Medical Record*, September 26, 1885. Vol. 28, No. 13, whole No. 777. W. Wood & Co., publishers, 56 and 58 Lafayette Place, N. Y. City. Abstract from same in *Journal of the American Medical Association*, Vol. V, No. 14, October 3, 1885, 65 Randolph St., Chicago, Ill. Medical and Surgical Reporter, November 28, 1885, Vol. LIII, No. 22, Philadelphia, Pa.

Out of last 19 cases up to date I lost two patients; these two were operated upon at their houses. The other 17 cases were operated upon and kept under my own immediate and constant observation at my private surgical home, no death.

I would also refer the interested reader to my papers on:

I cheerfully admit that I carefully select the cases I operate upon.

Selected Formulæ.

SPASM OF THE GLOTTIS.

Sir Morell Mackenzie finds that by exciting a rival reflex, the laryngeal spasm is at once overcome. By exciting a paroxysm of sneezing, immediate relief is procured. This is best done by the inhalation of a pinch of snuff into the nares, or pepper may be used in the same way. It is sometimes possible to produce sneezing by tickling the nasal mucous membrane.

ON EXPELLING TAPE WORMS.

In the Polish *Gazeta Lekarska*, No. 17, 1891, p. 327, Dr. Szczesny-Bronowski, of Tcherdyn, warmly recommends the following mixture, which invariably proves efficacious even in most obstinate cases where the usual administration of ethereal extract of male fern, or pomegranate bark, or cousso flowers, has failed:

℞

Extract filicis maris ætherei	℥iij.
Chloroformii	♏ij.
Emulsionis olei ricini	ex ℥vi--℥iij.
Syrupi menthæ	℥j.

M.

Sig. Divide in two equal portions and take both with half-hour intervals, early in the morning, on an empty stomach. The mixture should be well cooled down before using.

In the evening at bedtime, the patient's bowels should be thoroughly cleansed by means of calomel (6 grains) or an enæma. The tape-worm (be it a *tænia solium* or a *botheriocephalus latus*) is expelled, head and all, within four hours after the second dose of the mixture. The addition of chloroform to the latter is important in two regards: on one side, the drug narcotizes the parasite and thus promotes the detachment of its head from the intestinal wall; and, on the other hand, it prevents nausea and vomiting which are so commonly induced by the internal administration of the male fern extract alone.

GONORRHŒA.

I have found nothing equal to hydrastine in treatment of gonorrhœa.

℞

Hydrastine.....gr. i--ij.
Zinci acetatis
Plumbis acetatis } aa.....gr. j.
Apuæ puræ.

M. Sig. Use as an injection after washing out urethra with warm water. Internally, alkalies and copaiba.

—*McIntosh, N. Y. Medical Journal.*

SEAT WORMS.

℞

Tincturæ rhei.....gtt. xxx.
Magnesiæ carbonat.....gr. iij.
Tincturæ zingiberis.....gtt. j.
Aquæ q. s. add.....f℥iv.

M. Sig. Warm and use as injection three times daily.

—*The Doctor.*

Minerba states that he has achieved brilliant results from injections of naphthalin. He uses the following:

℞

Naphthalin.....gr. xv--xx.
Olive oil.....℥iiss--iij.

Sig. Use as injection.

—*Med. Brief.*

DIARRHŒA.

℞

Salol.....℥ij.
Bismuthi subnitratis.....℥iv.
Mist. cretæ, q. s. ad.....f℥iij.

M. Sig. One teaspoonful every two hours.

—*Buffalo Med. Jour.*

ELASTIC MUCILAGE.

Salicylic acid.....℥j.
Soft soap.....℥iij.
Glycerin.....f℥ xx.

Dissolve and add to a mucilage composed of

Acacia.....℥xij.
Water.....f℥xxji.

GUM ARABIC SUBSTITUTE.

Lime, slaked.....℥ 3iij.
Sugar granulated.....℥xij.
Water.....f℥xxij.
Glue.....enough.

Dissolve the sugar in the water, then boil and add the lime. In a few days the lime sinks to the bottom.

SULPHATE OF COPPER IN OBSTETRICS.

Tarnier (*Cblt. f. Gyn.*) has for some time been using a five per cent. solution of sulphate of copper for washing out the uterus and vagina after delivery, and is very well satisfied with the results. From control experiments made with streptococci and staphylococci, and from his clinical experience he believes that he has proved that in this substance we have a readily obtainable, cheap, very soluble, relatively non-toxic, and an unusually active disinfectant; although it is not entirely free from disadvantages. In cases where corrosive sublimate is contra-indicated, sulphate of copper should, he thinks, have the preference over every other antiseptic.

DIPHTHERIA.

J. Simon first thoroughly dries the diphtheritic membrane and then applies to the throat, by means of absorbent cotton, the following solution:

℞

Acid. salicylici.....gr. vi--xij
Alcohol q. s. to dissolve.
Glycerin.....f ℥j.
Infusion eucalypt.....f ℥iss. M.

The least adherent particles are detached, if possible, without injury to the adjacent mucous membrane. These applications are to be made every hour during the day and once in three hours during the night. If the false membrane is very thick and adherent, it is also to be treated with equal parts of the tincture of the chloride of iron and glycerine, two to four times a day. It is also recommended to irrigate the throat after every second application with a glassful of tepid Vichy or boracic acid solution (4–100). Internally a drop of the tr. ferri chlor. may be given in grog or bouillon every hour.—*L'Union Medicale.*

LABORDE'S ANTISEPTIC SOLUTION.

℞

Mercuric bichloride.....grammes 0.25.
Sodium chloride.....grammes 1.00.
Cupric sulphate.....grammes 1.00.
Glycerin.....grammes 10.00.

Dissolve. For use add one liter of water.

EGG LEMONADE.

Beat all together one goblet of water, juice of one lemon, white of one egg, tablespoonful of pulverized sugar. Good in inflammation of lungs, stomach or bowels.—*Annals Hygiene.*

ERYSIPELAS.

Cayet (*Cblt. f. Klin. Med.*) has obtained the best results by spraying the following solution on to the affected parts three times a day for about a minute:

℞

Hydrargyri chloridi corrosivi } aa gr. xxiv.
Acidi citrici }
Alcohol ..... f℥ij.
Ætheris ..... f℥v. M.

URINARY INCONTINENCE.

Watson recommends the following:

℞

Atropine sulphate ..... gr. j.
Distilled water ..... f℥j. M.

Sig. Twice daily (at 4 and 7 o'clock P. M), as many drops as the child is years of age.

—*Therapeut. Monatshefte.*

MILK FOR NEW-BORN INFANTS.

Prof. Parvin recommends the following preparation:

℞

Milk ..... f℥ iv.
Cream ..... f℥ iss.
Water ..... f℥ v.
Sugar of milk ..... ℥ j.

M.

To prepare it, use first the sugar of milk, then the milk, then the cream, then the water.

GASTRO-INTESTINAL CATARRH.

L. G. Broughton recommends the following mixture in severe cases, with profuse and watery stools:

℞

Salicylate of bismuth ..... ℥ ij.
Sulpho-carbolate of zinc ..... gr. iv.
Chalk mixture ..... f℥ i.
Paregoric } of each ..... f℥ ss. M.
Water }

One drachm of this should be given every two hours until the bowels are controlled, after which the following is prescribed:

℞

Calomel ..... gr. j.
Sulpho-carbolate of sodium ..... gr. xx.
Sacch. pepsin (P., D. & Co.) ..... gr. xix.

Divide in ten powders and give one every three hours. If the stomach is not irritable, sulpho-carbolate of zinc is substituted for the sodium salt in the last prescription.—*Therapeutic Gazette.*

INHALATION FOR ACUTE CORYZA.

Hayem has found relief, though seldom cure, follow inhalations of carbolic acid and ammonia. He recommends the following formula:

℞

Pure carbolic acid.
Water of ammonia, aa ..... f℥ j.
Alcohol ..... f℥ ij.
Distilled water ..... f℥ iij.

Sig. Pour a few drops on thick blotting-paper and inhale the fumes for a few seconds.

—*Record.*

CHLORALAMID IN SURGERY.

Dr. Emory Lanphear, of Kansas City, regards chloralamid as an excellent hypnotic, when such a remedy is needed after a surgical operation. He gives from fifteen to thirty grains, dissolved in whiskey, repeating the dose in an hour if the first has not produced the desired effect. He suggests the following as a good formula for the exhibition of the drug:

℞

Chloralamid ..... ℥ ij.
Spts. frumenti ..... f℥ j.

Misce bene et ft. solut. et adde:

Syrupum rubi idæi ..... f℥ j.

Misce. Sig. Dose, one tablespoonful, to be repeated in one hour if sleep is not produced.

This makes a decidedly pleasant mixture of slightly acid taste and fruity aroma and flavor.

CORYZA.

Rex advised the following plan of treatment: Place the patient in a well-ventilated room, with a temperature of about 70° F. Have the patient to wear warm clothing. Rub the chest with some mild rubefacient. If feverish, a foot bath or some fever mixture; later, some expectorant mixture in which there is carbonate of ammonia or syrup of senega. He gave the following prescription:

℞

Tincturæ scillæ ..... ℿ j.
Vini ipecac ..... ℿ j.
Syr. tolu ..... ℿ xx.
Aquæ gaultheriæ ..... f℥ j.

M. Sig. Every two hours.

Every hour or two the patient should take some albumin water, which can be made by taking a pint of lukewarm water and dissolving in it the white of one egg.—*Times and Register.*

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

EDWARD T. REICHERT, M. D.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF PENNA.,
EDITOR AND MANAGER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

THE MEDICAL AND SURGICAL REPORTER.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent 3 months on trial for $1.

At the termination of the period of subscription, we will promptly discontinue sending THE REPORTER unless directed to the contrary by the subscriber.

Remittances should be made by draft, check, postal note, or money order payable to Edward T. Reichert.

THE POCKET RECORD AND VISITING LIST.

Two sizes. Prices to subscribers of THE REPORTER: For 30 patients a week (with or without dates), $1.00. For 60 patients a week (without dates), . . $1.25. Prices to non-subscribers, $1.25 and $1.50 respectively.

THE MODEL LEDGER.

Physicians who keep their own books will find this of great value. Sample pages sent on application. Price, $5.00.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If THE REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS.

Write in ink.

Write on one side of paper only.

Write on foolscap or legalcap paper.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be pleased to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

LEADING ARTICLE.

THE STATUS OF THE HYDROCHLORATE OF COCAINE AS A LOCAL ANÆSTHETIC.

The use of cocaine as a local anæsthetic has had the crucial test of time to determine its merits and to prove its utility. Therefore it has passed the experimental stage and has reached the point when we can speak authoritatively on its status as an agent for the local relief of pain in the minor operations of surgery.

Like other remedies, it has a legitimate field of usefulness, and when employed outside of this limit, it is liable to cause both disappointment and possible disaster. When properly used, its action is entirely satisfactory and its employment is attended with as much safety as surrounds the use of any of the well-known anæsthetic agents—either general or local.

It is the misuse of cocaine, the neglect of essential details, which is so often followed by unsatisfactory results, and at times, unfortunate, not to say alarming complications. Such effects are not attributable to the proper employment of the drug under consideration. The use of any anæsthetic, always involves a certain degree of danger; but this fact is not urged as a reason for abolishing the use of these agents; therefore, it should not be used as an argument against the use of cocaine.

In the August issue of the *Therapeutic Gazette*, Dr. Lewis H. Adler, Jr., has an article entitled: "*The status of the hydrochlorate of cocaine in minor surgery, as based upon the experience of Philadelphia physicians.*" In this paper, the author records the views of over fifty gentlemen of this city, regarding their personal opinions as to the merits of the drug as a local anæsthetic. From these replies the author bases the following summary:

1. *In minor surgery,* cocaine, used hypodermically, is of value in all operations in which the circulation can be temporarily arrested, in order to prevent undue absorption of the drug, and, in which free bleeding can

be encouraged at the completion of the operation previous to the tying of the sutures, to allow as much of the unabsorbed cocaine to be washed out as is possible. Attention paid to these two essential points will, as a rule, obviate any untoward results from the use of cocaine employed hypodermically, for anæsthetic purposes. It is likewise important to make use of freshly-prepared solutions, as otherwise the formation of fungi is liable to occur and the preparation to be spoiled. To prevent this alteration, antiseptic agents are added, the best one being boracic acid, as it is the least irritating. Such a solution usually consists of about twenty grains of cocaine and ten grains of boracic acid, dissolved in an ounce of distilled water. *A preparation of this character has been used by the writer with perfectly satisfactory results, even when it has been several months old.*

Another point of considerable importance is to make use of a perfectly aseptic syringe; frequently, in cases where cocaine is used hypodermically, and suppuration follows, it is the fault of want of cleanliness in this particular, and not to the employment of the drug.

A four per cent. solution is as strong as need be used for hypodermic injections. The principal advantages in using a solution of no greater strength are, that the anæsthetic property of cocaine can be made to reach to a larger area with a less amount of the drug than is the case when a more concentrated one is employed; and, furthermore, the dilution of the drug renders it less liable to produce toxic symptoms.

When the circulation cannot be controlled, extreme caution must be observed in the use of the drug, especially is this the case when any considerable quantity is required.

In anal work, cocaine is not of much use as a local anæsthetic; when so used it must be employed cautiously. It is of no use in obtunding the pain of fistulous tracts or of fistulæ *in ano*. Toxic symptoms are apt to ensue when the drug is employed in this region. The rich lymphatic and vascular supply of the part probably accounts for this fact.

For the purpose of controlling the circulation, a piece of elastic tubing is to be preferred to a solid ligature, as less damage is done to the soft tissues and more uniform constriction of the part is obtained.

In amputation of fingers and of toes for injury, less pain is occasioned the patient if the primary injections are made through the wound, reserving the punctures through the skin until a later period, when the sensitiveness of this structure may be made use of in determining the degree of anæsthesia produced.

The quantity of cocaine required to produce anæsthesia varies with the operation and its extent; as a rule, for ordinary minor operations, from twenty-five to forty minims of a four per cent. solution are needed. The length of time necessary for the production of local insensibility under cocaine varies from three to ten minutes.

Individual susceptibility to the toxic influence of cocaine is a complication of sufficient frequent occurrence to surround the use of the drug with due care and caution, but it is not a contra-indication to the employment of the agent as an anæsthetic. Untoward effects may arise from the use of any one of the anæsthetic substances.

Another objection urged by some surgeons to the employment of cocaine for anæsthetic purposes is based on its asserted power of inducing the so-called "cocaine habit." As yet, this influence of the drug is extremely rare. It is most liable to occur among the patients who are informed the nature of the remedy used, and especially is this the case when it is employed internally for medicinal purposes. It is hard to believe that this action of cocaine can be produced when it is employed for its local anæsthetic effect and in the small quantity needed to induce local insensibility.

2. *In genito-urinary surgery*, cocaine is to be used with more than ordinary care as it is in this class of cases that the untoward effects of the drug have been most frequently noted. It is successfully employed to allay excessive irritability of the urethra before the passage of sounds or of bougies; it is important, in such instances, not to allow the solution to

remain in contact with the mucous surface more than a few moments, and to subsequently encourage the outflow of any excess.

In the operation for circumcision, the anæsthetic action of the drug is prompt and efficacious, but it is important to remember that the circulation must be controlled before the injections are made, and that after the foreskin is removed and the sutures inserted, but not tied, that the ligature employed to regulate the blood-supply is removed and free bleeding allowed, that as much of the drug as possible may be washed out of the system.

For the purpose of preventing the pain incident to the removal of venereal warts, or in the cauterization of venereal sores, the drug is satisfactory.

For the production of anæsthesia, previous to the operation of internal urethrotomy, opinions differ as to its efficacy and to the danger involved of producing the toxic effects of the drug. The weight of evidence seems to prove that cocaine is not to be employed indiscriminately in these cases, and when used should be administered with caution and with a knowledge of the possible risks involved. That it is possible to avoid any untoward effects from its use in the operation is shown by the testimony of Dr. John B. Deaver, who has employed cocaine in a large number of operations requiring internal urethrotomy without experiencing the slightest ill-effect to the patient.

3. *In gynæcological practice,* the drug has a limited field of usefulness. As a rule, in operative procedures classed under this head, general anæsthesia is to be preferred, as the patient's knowledge of the exposure of her person is often quite sufficient to unnerve her for the operation, and may even be the means of frustrating the surgeon's work.

For slight operations and those easy of performance, such as the extirpation of vascular vegetations at the mouth of the meatus urinarius, the removal of stitches from the vagina, etc., anæsthesia from cocaine is all sufficient. For the vaginal examination of highly nervous and hyperæsthetic women, cocaine, applied to the orifice of the canal, will render comparatively easy an otherwise difficult operation. For the primary repair of the perineum, when an anæsthetic is indicated, a dossil of cotton saturated with a solution of the drug and placed in the wound will accomplish the desired purpose.

4. *For ophthalmological work,* the surgeon finds in cocaine the anæsthetic *par excellence.* In no other department of surgery do we find its use so widespread and its application so entirely satisfactory. While this is true, it must be remembered that to obtain the best results it is more essential here than elsewhere to employ a perfectly pure drug in a freshly-prepared solution. Many of the untoward effects ascribed to the use of cocaine in eye surgery are due undoubtedly to the neglect of these two essential points.

All of the operations upon the eyeball may be performed under cocaine anæsthesia, except iridectomy for acute glaucoma and enucleation. Even in the latter instance, according to Dr. Albert G. Heyl, where the patient does not come under the influence of the general anæsthetic, or when it is desirable to shorten the duration of the operation, the instillation of a solution of cocaine enables one to begin it earlier than would otherwise be possible; he, therefore, sees no reason why the drug should not always be used in the operation with this object in view.

Owing to the effect of the drug on the cornea in producing drying of the epithelium, it is essential not to use it too long a period before an operation, and, when it is instilled, that the lids be kept closed until the moment of beginning the same.

5. *In operations upon the ear, nose and throat,* cocaine is of great value as a local anæsthetic. It is also of use as a means to render diagnosis of the condition of these parts easier and more certain.

In aural work, according to the testimony of Dr. B. Alex. Randall, brucine excels cocaine as an anæsthetic, and morphine and atropine as analgesics. In nasal cases the drug is of extreme value both in the study and the treatment of abnormal conditions. Dr. J. Solis-Cohen and Dr. Carl Seiler both

speak in the highest terms of its use as an anæsthetic in operative procedures upon the nasal chambers.

For the purpose of rendering the exploration of the larynx easy, the excision or scarification of the tonsils painless, and to permit the painless removal of pharyngeal neoplasms, elongated uvulæ, etc., cocaine is the anæsthetic indicated.

Correspondence.

TWO CASES OF HEART-FAILURE.

Two peculiar cases of heart failure have come under my observation that seem worthy of mention. The first one was that of a girl 15 years of age, very intelligent, with no hysterical tendencies. Whenever she ate fish of any kind she would in a short time be attacked with extreme fainting, and sensation of suffocation; the heart at such times beating slowly and with great feebleness. These symptoms would appear within one hour after eating, and sometimes almost immediately of the ingestion of fish. The amount of fish taken made no difference in the violence of the symptoms. Stimulants were given and speedily followed by relief, but sometimes the tendency to syncope lasted several hours. No other substance was known to produce the symptoms. On one occasion she was attacked when she had not been eating fish, when she went through with all the distressing symptoms following a meal of fish. I inquired carefully after every article she had tasted for dinner and found nothing of a fish nature that she had taken. On collecting her thoughts she remembered that in fixing her bonnet just before dinner she used some fish glue and got some into her mouth, but swallowed none of it. This accounted for her syncope.

Another girl, aged about 19 years, not accustomed to faint on any other occasion except when going into a room lighted with electric lights. She feels a peculiar sensation on entering the room, but may not faint until she returns home, when it will come on and last an hour or more. She never can enter the presence of an electric light without feeling the heart failure coming on. No other kind of bright light, however strong, has the same effect.

John M. Currier, M. D.,
Newport, Vermont, August 5, 1891.

GUAIACOL IODIDE IN THE TREATMENT OF CONSUMPTION.

Editor of the Medical and Surgical Reporter:—The weak affinity possessed by iodine for the organic groups, and the comparative low temperature at which its organic compounds are decomposed with the separation of free iodine, suggested this combination as a proper remedy for keeping in abeyance that form of tuberculous disease of the lungs, where a powerful antiseptic is required.

From the above it would seem reasonable to believe, that those remedies which are vaporized at the ordinary temperature of the body, are taken into the circulation through the medium of the lungs, as readily as when they are injected into the cellular tissue. The introduction of this class of antiseptic remedies into the lungs, and their rapid decomposition—a result of their weak chemical affinity would lead us to expect the most perfect exhibition of their therapeutical properties, from the fact that they are delivered to the blood in a nascent state, which is well known to be the most active condition in which chemical bodies exist. This expectation has been realized in practice, to an extent to warrant the expression of an opinion that the acute, and sub-acute stages of consumptive disease of the lungs, can in many instances be kept under control by this remedy.

Wm. H. Gregg, M. D.,
New York City.

Obituary Notice.

DR. J. REED CONRAD.

Dr. J. Reed Conrad died of pneumonia, August 12th, 1891, at his residence on Twenty-second street, in Philadelphia, at the age of 34. He was a descendant of the Conrad family, which, with thirteen other German families became converts to Quakerism under the teachings of William Penn, and emigrated to America in 1682, and were the first settlers of Germantown.

Dr. Conrad graduated from the Medical Department of the Pennsylvania University in 1879, and was actively engaged in his professional work until his fatal illness began. His devotion to his duty was constant, and his many lovable qualities brought him friends wherever he went. He held active appointments in some of the most prominent medical institutions in this city. He was Chief of the Chest Clinic in

the Philadelphia Polyclinic; Physician to the Out-Patient Department of the Rush Hospital for Consumption; and Chief of the Medical Department of the Union Dispensary. His opportunities for the investigation of disease were of the best, and he took advantage of them with exceptional zeal and enthusiasm. He had a great longing to make the diseases of the chest his life-study, and one of the very disorders, the investigation of which always gave him unfailing interest, was destined to become his mortal enemy. So far as the writer knows his literary contributions to medicine were limited; but at the time of his death he was engaged in gathering clinical material for a paper on the relationship between chest-pains and certain cardiac lesions. He was laid to rest, August 17th, in Laurel Hill Cemetery.

PERISCOPE.

THERAPEUTICS.

ANTIPYRIN IN TETANUS.

Alexandre Paris (*L'Union Méd.* No. 8, 1890) reports the case of an old man who developed symptoms of tetanus—it is not stated whether traumatic or idiopathic—in the middle of June. He improved under chloral, suffered a relapse on the 8th of July, which developed into a widespread involvement of the muscles of the thorax, abdomen and lower limbs; was uncontrolled by chloral, but which, on July 28th, was rapidly alleviated by 13-gramme doses of antipyrin repeated on the two succeeding days, after which not a muscle was convulsed. The drug was administered for the relief of pain in the limbs with the unexpected result not merely of curing this, but of relaxing the spasmodically contracted muscles.

The *University Med. Magazine* calls attention to this single observation in regard to antipyrin, "though unaware that our present knowledge of its physiological action justifies any sanguine expectations, because one case may form a nucleus for others sufficient in number to justify definite conclusions, and because new facts, as the author himself hopes, can alone answer the query of coincidence or cure."

MASSAGE OF THE STOMACH IN THE TREATMENT OF GASTRIC DYSPEPSIA.

Cseri (*Revue de Thérapeutique*, April 15, 1891) employs massage in the treatment of gastric dyspepsia. Two or three hours after a full meal, the patient is placed in the dorsal decubitus, with thighs flexed on the pelvis and the mouth open. The gastric region is first very lightly stroked, the force then being gradually increased to a veritable kneading, always in a direction toward the pylorus. The whole process should last about ten minutes. This massage not only hastens the passage of food into the duodenum, removing at the same time the badly digested and altered remains of previous meals, but also stimulates the contractility of the muscular coat of the viscus and increases the secretion of gastric juice. A short massage of the large intestine should end the séance. The only contra-indication is the existence of complications, such as ulcer or other conditions which may cause hæmorrhage. This treatment is said to be followed by a pleasant sense of relief and often by refreshing sleep. —*Univ. Med. Mag.*

TREATMENT OF CHRONIC ECZEMA BY CREOLIN.

Dr. Patteson read a note on the treatment of chronic eczema by creolin. He had been led to adopt its use from the well-known value of tarry preparations in certain forms of eczema and psoriasis, and from its cheapness, which rendered it suitable for out-patient practice. He briefly referred to two cases of pustular eczema of the scalp—one of eight and the other of three years' standing—in which marked improvement and cure followed its prolonged use. It was applied as a wash or lotion in the proportion of one drachm to eight ounces of water. The value of such a powerful germicide in these cases seemed in favor of Unna's contention as to the parasitic nature of eczema. The President congratulated the Academy on the additional remedy for chronic eczema which Dr. Patteson had brought under their notice. His communication, however, did more, and that was, that it emphasized the importance of perseverance in the treatment for eczema which had been found temporarily useful.—*Lancet.*

THE TREATMENT OF CHRONIC CONSTIPATION.

Dr. T. Flotau recommends for this purpose

the direct application to the rectal mucosa of about 3 grammes of powdered boric acid. In cases where the mucosa cannot be reached, insufflation of the same quantity of powder is employed. In from ½ to 3 hours after the application peristalsis occurs attended with copius fæcal evacuations. The evacuations may occur 2 or 3 times during the day and are never painful. This method never fails in properly selected cases. Experiments made with other remedies yielded negative results. There is no fear of intoxication, as indicated by a large number of cases treated. In three cases failing to yield to other remedies boric acid accomplished the desired result.—*Berlin. klin. Wochenschr.* March 2d, 1891.

TREATMENT OF CHLOROSIS BY SUBCUTANEOUS INJECTION OF IRON-SALTS.

Subcutaneous injection of iron-salts in the treatment of this affection is recommended by Magagni (*Deutsche Medicinal-Zeitung*, April 30, 1891, from *Raccoglitore med.*, 17 and 18, 1890). The pyro-phosphate, citrate, or citro-ammonium pyro-phosphate may be employed in dose of three grammes in a five per cent. solution. The injection is made subcutaneously, preferably in the nates, with a long needle, so as to deposit the solution some distance from the point of puncture. After this a gentle massage of the spot is made to favor distribution and absorption of the solution. Ten cases are reported, all of which were promptly cured by this plan of treatment.—*Univ. Med. Mag.*

PHYSIOLOGICAL STUDY OF CHLORALAMID.

Dr. H. C. Wood and Dr. David Cerna published a paper in *New Remedies* in which are the following conclusions:

Our researches have been made solely upon dogs, and therefore the following conclusions apply directly to those animals.

First. Chloralamid has a slight local influence, and in large doses tends to produce mucous diarrhœa.

Second. It acts more powerfully upon the cerebral cortex than upon any other portion of the nervous system of voluntary life, thereby causing sleep and muscular relaxation; but it is also a feeble spinal depressant.

Third. It has a powerful influence upon the respiration, in moderate dose, by a centric action stimulating the respiratory rate, and probably also increasing the actual amount of air breathed; but in toxic dose causing death by paralysis.

Fourth. Its influence upon the circulation is a very feeble one; the changes produced by small doses being probably secondary to other effects of the drug; toxic doses, however, depress the arterial pressure by a direct action either upon the heart or upon the muscle coats in the arterioles.

THERAPEUTICALLY CONSIDERED.

The results of our experiments indicate that chloralamid is very worthy of trial as a hypnotic. Its action upon the heart is so slight that it bids fair to be valuable as a hypnotic in cases of feeble heart; whilst its stimulating influence upon the respiration would seem to fit it for employment in cases of nervous exhaustion. The exact clinical value of a hypnotic can, however, only be determined by clinical study. Dr. H. C. Wood has used the remedy to a moderate extent in various forms of insomnia, and so far it has seemed to him to be slower and less certain in its action than is chloral. Rarely have unpleasant after-effects been noted, but he has seen in some cases distinct headache. The statement of Hagen and Hüfler that the drug is especially valuable in cardiac asthma seems to be consonant with our experimental conclusions.

METHYLACETANILIDE, OR EXALGIN.

In the *Bull. Gén. de Thérapeutique*, No. 6, 1891, Desnos has made a study of the merits of this drug. He says that the chemical formulæ of exalgin confirms the law established by M. Dujardin-Beaumetz, to wit: that the anti-thermic action will be especially developed in amidogenous derivatives, whilst the analgesic property will be at its maximum in the amidogenous bodies in which for one molecule only of hydrogen, one molecule of a primitive fat, especially of methyl, has been substituted. Exalgin presents itself in the form of a white powder, consisting of long, fine needles, absolutely tasteless, soluble in warm alcohol and in boiling water, but slightly soluble in cold water to which a small proportion of an alcoholic fluid has been added. The physiological effects produced by it in man are very interesting. The action of the drug seems to be entirely exerted upon the bulb and the cerebro-spinal system. Prominent in the impressions produced upon the brain is vertigo. The numerous varieties in which this presents itself are interesting. Sometimes, and this is most frequently the case,

very quickly after the ingestion of the drug the patient complains of a slight mist, as of a veil stretched before the eyes, and this is all. This sensation may be fugitive; its duration is very variable, oscillating between five minutes and a half hour. Sometimes the patients have a sensation of rotation within themselves, or yet it is the surrounding objects which appear to them to revolve around them. In a woman it seemed that her bed sank into the floor, another believed that she was incessantly falling to the side of her bed, and one even grasped the opposite side of the bed to escape falling. These extreme cases are very rare. In general the patient is able, notwithstanding the vertigo, to rise and walk. As a rare exception the vertigo is accompanied with vomiting, and also rarely with chills or cold sensations. In certain patients, but rarely, the vertigo coincides with tinnitus aurium, or this may be replaced by heaviness of the head or by cephalalgia, by a tendency to sleep, or simply a state of torpor, which two patients compared to that in which they had previously been thrown by injections of morphine. Nevertheless, it should be remembered that exalgin is no more a hypnotic than it is an anti-thermic. If the patients sleep, it is because the drug has freed them from the pains which had kept them awake. Some other phenomena reveal an action upon the cord and spinal nerves. Thus, sweats are encountered which may be general and profuse, or limited at times to one region of the body, generally to that portion which is the seat of the malady for which the exalgin is administered. Thus, also, frequently tinglings are experienced, extending to all the members and the tongue, or solely to the points where the neuralgia exists. Some patients complain of flashes of light before the eyes.

All doses may provoke these nervous phenomena. Three and three-quarter grains may suffice, but it is generally when eight and a half grains have been injected that they may be observed. Then, again, large doses, eleven or twelve grains, may fail to produce them. In this dose, however, cyanosis may be observed, though of slight intensity, and not in any manner resembling the cyanosis of grave disease of the heart. The appearance of the free border of the lips is scarcely modified, and upon the skin of the upper and lower lip, and upon the naso labial ridge, a slight grayish-blue tint may be observed. This coloration is not of long duration, usually disappearing on the next day. An examination of the blood of patients to whom exalgin has been administered reveals an alteration of the globules, which seem to be almost, if not completely paralyzed, so that the gaseous changes are not carried on in the proper manner. There is also a diminution of the oxy-hæmoglobin. Exalgin, therefore, has the property of giving rise to anæmia, although this is not a property exclusively belonging to it, but one that is shared by the other anti-thermic nervines. One of the interesting points in the administration of exalgin is the ease with which it is tolerated by the digestive tube. It does not engender any troubles of the stomach or intestines.

As to the dose of the drug, three and three-quarter grains at times suffice to produce a curative effect, complete and lasting. More than this should never be given at a time, but if need be the dose may be increased to two or three times this amount during the twenty-four hours. As M. Gandineau has shown, a tolerance for the drug may be established, so that in giving successive doses it may become necessary to increase the amount given. The affections in which exalgin is of the greatest service are the neuralgias, especially the facial neuralgias, involving one or several branches of the trigeminal, or the occipital nerve, especially if these are of congestive origin from cold or rheumatism. The anæmic neuralgias are, without doubt, very favorably influenced by exalgin. Intercostal neuralgias have been benefited, as also have been neuralgias of the various plexuses, and the ilio-lumbar pains consequent upon uterine and ovarian disease. The visceral neuralgias, angina pectoris, and nephritic colic are benefited, as are also painful and hysterical menstruation. The tremblings of paralysis agitans may be controlled by its use.—*News.*

BANANAS IN CHRONIC BRONCHITIS.

In cases of chronic bronchitis with difficult breathing and scanty expectoration the use of banana-juice has been highly praised. The juice is prepared by cutting up the bananas in small pieces and putting them, with plenty of sugar, in a closed glass jar. The latter is then placed in cold water, which is gradually made to boil. When the boiling point is reached the process is complete. Of the syrup so made a teaspoonful every hour is the proper dose.—*Record.*

MASSAGE IN CHRONIC DYSPEPSIA, DUE TO MUSCULAR ATONY.

This form of dyspepsia is very frequent, usually accompanied by dilatation of the stomach, unattended by local pain, and resists the treatment by the alkalies, hydrochloric acid, nux vomica, electricity, and the revulsant application of plasters, of cold and of heat. Dr. Sédan employed massage in the following manner: With the hand, well-oiled previously, he kneads the stomach in a direction from the cardiac to the pyloric end, making gradual and deep pressure. Without changing the direction the pressure should be gentle, deep, and constant. The fingers should then go through the same movements in the opposite direction. At the end of five or six minutes massage is applied to the entire right iliac region for several minutes. There is usually an escape of gases both by the anus and mouth; and after two or three daily seances continued for five or six days, surprising results are obtained. The procedure is best practised two or three hours after the meal, and in general before the time at which the patient experiences the greatest discomfort. Under this treatment the appetite and sleep are improved, and it is always successful when there is a partial or complete reflex insensibility of the stomach. It has also caused the disappearance of obstinate chronic constipation.—*Gazette Médicale de Liege.*

THE HYPNOTIC ACTION OF URETHANE, SULPHONAL, AND PARALDEHYDE, CLINICALLY CONSIDERED.

Dr. T. Sydney Short, in the *Birmingham Med. Rev.*, gives the following summary of his study:

Age and Sex.—The extreme ages of the patients in the list were 14 and 59 years, and of the 26 cases, 20 were males and 6 females. I could not see that the age or sex affected the action of the drugs in any way.

Disease.—Here it was evident that the drugs had little effect upon cases of sleeplessness due to pain; in the case of thoracic tumor, however, where pain, but not very severe pain, was present, the patient stated that he was certainly easier after the draught containing gr. xxx. of sulphonal. On the other hand, in the case of thoracic aneurism, where again the pain was not very severe, the same drug in doses of from gr. x. –xx. had no effect whatever. Five out of the seven cases of heart disease were greatly relieved, one had a little sleep, but the seventh was not much benefited. In the cases of bronchitis with cardiac failure, they gave good or fair nights and will probably prove to be most useful in this class of case where opium is contra-indicated. In one of the cases of chorea, sulphonal in gr. xx. doses acted most satisfactorily; better I think than the same amount of chloral would have done, although of course, it is impossible to be sure of this. In the other case of chorea, neither the urethane nor sulphonal gave more than a few hours' sleep at a time. In the cases of convalescence after pneumonia and enteric fever, all three drugs proved of great service; after the first good sleep no further dose was required. It appeared as if the bad habit of not sleeping had been broken.

Advent of Sleep.—The times at which sleep ensued were so various that it is not easy to draw any definite conclusions from them. Ten minutes on the one hand, and six or seven hours on the other seemed to be the extreme limits. Both urethane and paraldehyde have probably a more rapid action than sulphonal, but not in my cases to the extent usually considered, for sulphonal in ʒ ss. doses produced sleep in a few minutes on one occasion, and in fifteen minutes on as many as five occasions. The action of sulphonal may be deferred for some hours; on two occasions sleep did not ensue for six or seven hours, and in several cases the sleep seemed better the night after, than on the occasion of the first dose, even when only one was given, but I do not remember any occasion on which no sleep at all was enjoyed on the night of administration, and a good or fair night the next, without a repetition of the draught.

Duration and Character of Sleep.—In the greater number of the cases where sleep was produced it was good in quality while it lasted. If the patient had been wandering or talking much in disturbed sleep for several nights before the drug was given, the sleep following the draught seemed more likely to be accompanied by occasional wandering than when the drug was given for complete absence of sleep with rational wakefulness. It seemed to me that slight wandering was more likely to occur after sulphonal than after either of the other drugs; or, to put it in another way, that after urethane and paraldehyde the patient might wake up for a few minutes and then drop off to sleep again quietly, whereas after sulphonal the wakeful intervals seemed to be replaced by wandering intervals, followed again by sleep of a sounder nature. I thought that sulphonal stupefied the patient more than paralde-

hyde, and certainly more than urethane; and in one case the patient, after gr. xxx. of sulphonal, seemed inclined to wander and talked nonsense before he went to sleep at all.

After Effects.—In nearly every case in which any effect was produced, drowsiness ensued the morning after the drug had been given. The feeling of drowsiness was most powerful after sulphonal, and in fact often produced good sleep during a large portion of the next day. Slight headache was produced in a fair proportion of the cases, and some amount of giddiness in a few only. Following the moderate doses prescribed, no really disagreeable consequences were experienced. In two cases skin eruptions were seen; these have already been referred to. It is reasonable to conclude that they were actually caused by the drug. In one case rashes appeared both after paraldehyde and after sulphonal; in the other, after sulphonal.

General Effects—I cannot point to any derangement of respiration, circulation, or appetite as a result of the drugs administered. If any alteration did occur in the respiration or circulation, it was not noticeable on the ordinary ward charts, and no symptoms occurred to suggest it. No case of cyanosis was seen after the administration of sulphonal.

I think the manner in which the chosen drug is given is important. The best results were those in the cases where sleep speedily ensued, and slight disturbances such as those unavoidable in a large ward were sufficient to prevent the approach of sleep in several instances. On every occasion, so far as it was possible, the patient was prepared both bodily and mentally for a good night's rest; the last day medicine and the last food had been given, the pillows and bedclothes rearranged, and the spit cup or other toilet requisite placed ready, so that he need not be disturbed, and he was told to remain quite still after the draught. Quietness of this nature can be more easily ensured in private than in Hospital practice, and on that account the drugs have a better chance in private than under the more or less disturbing influences of a Hospital ward.

In conclusion, I think that this brief article, although not sufficiently extended to prove more than a few points, and subject, as all like papers will be, to fallacies such as that of the *expectation of sleep on the part of the patient*, yet will tend I think to strengthen the belief that, if given in suitable cases, in urethane, sulphonal, and paraldehyde we have three most useful and valuable drugs.

MEDICINE.

CONVULSIONS A CAUSE OF CEREBRAL HÆMORRHAGE.

Henry Ashby, M. D., of Manchester, England, in an interesting article in the June number of the *Practitioner*, takes the position that paralysis following convulsions, in the early years of life, is quite frequently caused by intracranial hæmorrhage, due to the convulsions. After admitting that the convulsions and hæmorrhage may be both due to the same cause, as in softening from tuberculous meningitis and arteritis, he goes on to say that in many cases this causation is not present, and in at least a part of these the convulsion is the direct cause of the hæmorrhage. If the paralysis persists after a convulsion, or very slowly disappears, hæmorrhage is to be suspected. The paralyzed limb usually becomes stiff, and epilepsy is by no means an infrequent result. Goodhart, Algel, Money and Oster, have expressed a similar opinion as to the causal relationship between the convulsions and the hæmorrhage, but most authors do not concede it. In support of his views the writer reports a case which had come under his notice, as follows:

G. L., aged twelve, suffering from tuberculosis and hemiplegia, was brought to the Children's Hospital, Manchester. He was quite healthy and well developed until two years of age. There was no history of hereditary syphilis. At two years of age he had a fit, and two weeks later a more severe one. After this his right arm was useless, and he dragged his right leg. The convulsion had been most marked on the right side. The fits continued at intervals from this time until two years ago, since which time they have not occurred. From two to ten years of age they averaged about two a week. They were mostly right-sided. Arm and leg improved slowly after the second fit, but have remained more or less stiff and rigid. The approach of a fit was indicated by a commencement of twitching in the thumb of the right hand. His right leg still dragged at the time of examination, and the arm and leg were stiff and rigid.

He died of tuberculosis, and at the autopsy a half dozen or more old cysts, with brownish contents, were found in the white substance of the hemispheres, the chief of

which was found in the white substance of the left lobe, between the arm centre of the cortex and the internal capsule. They were evidently the remains of old hæmorrhages, and the author, we think rightfully attributes them to the convulsive seizures. The author also says the case is of interest, as showing a condition which could not have been remedied by operation.—*Cinn. Lancet and Clinic.*

RETENTION OF URINE.

In a case of retention of urine in a boy, ten years of age, who had been under treatment nine days for relief of an obstruction of the bowels caused by fæcal impaction in the cæcum, I found it impossible to practise catheterization, on account of the extreme timidity of the patient; and attempting chloroform anæsthesia, was forced to desist, as he ceased breathing on the slightest approach of insensibility. Having a four per cent. solution of cocaine with me, I injected forty minims into the urethra, compressing the meatus for about five minutes, and then requesting him to make an effort at micturition; he did so with perfect ease, and at each subsequent requirement the same proceeding was employed, until the necessity for its use was overcome. Its use produced no unpleasant effects, and it proved a happy factor in overcoming a very troublesome complication. As no opium was being used in the treatment, the retention was plainly from reflex irritation, causing spasm in the membranous portion of the tract.

GEORGE C. IRWIN, M. D.
—*Archives Pædiatrics.*

ILEUS OR INTESTINAL OBSTRUCTION.

The diagnosis of ileus presents many difficulties, first as to its differentiation from peritonitis, and then as to the classification of the different varieties of ileus in regard to locality and nature of the obstruction. Opium is an appropriate remedy in the beginning of ileus as well as in peritonitis, although, of course, for the former affection operative procedures are the last resort.

Ileus may be due to a variety of conditions. They are: First, strangulation from adhesions, from gluing together of coils of intestines, or from diverticula; second, invaginated and longitudinal twisting; third, there are strictures produced by tumors, scars and foreign bodies, which get caught in strictures.

Of the above conditions, invagination is the one easiest diagnosticated. It is characterized by palpable tumor, tenesmus and bloody stools.

Wahl has pointed out that in strangulation and longitudinal twisting of the gut, we may distinguish resisting inflated intestinal coils at the site of obstruction, provided there is not too much meteorism present.

If there has been previous perityphlitis, peritonitis or strangulated hernia, we may expect to find constricting bands. Again, the presence of a stricture or chronic constipation are valuable factors in the forming of our diagnosis.

In determining whether the site of obstruction is in the small or the large intestine, the following is a valuable though not infallible rule; the higher up the point of obstruction is located, the sooner and the more violent will the vomiting be.

From a therapeutic standpoint, it is advantageous to make two groups of ileus cases.

1. Strangulation-ileus, produced by strangulation by bands of internal hernia, by invagination, or by twisting. In this group, the circulation of the gut sooner or later becomes obstructed, and there is danger of gangrene and perforated peritonitis.

2. Obturation-ileus. In this variety the bowel is simply choked up; the affection is less dangerous, more chronic in character. The part of the intestines above the site of obstruction gradually fills up. Vomiting, therefore, does not occur until later on. Patients suffering from this kind of ileus do not suffer from the shock and collapse present in the first variety. When, finally, the bowel gets filled up, inflation and vomiting make the differentiation of obturation from strangulation-ileus more difficult.

The occurrence of peritonitis symptoms are very disagreeable and unfavorable. They consist, usually, of great tympanites, rapid pulse and speedy death.

If it were possible to always distinguish the two above described groups of ileus, we could form a clearer view as to the proper treatment of each particular case.

In obturation ileus, it is proper to rely at first on internal medicine. Begin with opium. Then wash out the stomach and bowels. Eventually resort to puncture of the intestines. These remedies usually succeed. Opium quiets pain and peristalsis, and in this respect it is an admirable drug. But we must remember that it also obscures the symptoms of the disease. Stomach washing, no doubt, does good by clearing out the upper intestinal tube, thus easing the patient; sometimes relieving the obstruction. Puncture is sometimes useful, though not as free

from danger as represented. The injection of water high into the bowel is a very valuable measure. It softens the fæces, and may wash away hard obstructing masses. It may also untwist a loosely twisted intestine. Warm water enemata are borne better and occasion less tenesmus than cold water enemata.

Absolutely no food should be given by the mouth. Ice water the patient may drink to quench his thirst, and nutrient enemata must nourish him. Under the foregoing treatment we can wait quite a while.

After a time there comes a state of intoxication due to absorption of the foul contents of the intestines, and there is then also danger that the bowel, weakened by over distention, will perforate.

In strangulation-ileus the therapeutic requirements are altogether different. The circulation of the bowel is interfered with, and the fearful consequences of this condition must induce us to do early laparotomy, whenever our diagnosis is certain. Exactly when to operate depends on the peculiarity of each particular case. In the case of ileus with acute symptoms, fæcal vomiting and shock, if there are scars on the abdomen, pointing to a previous operation, or if inflated coils of intestine can be distinguished, we must never wait longer than 72 hours before operating.

We may conclude, therefore:

In the beginning of ileus we should first give internal medicine a trial, in the meantime trying to perfect our diagnosis as to the actual anatomical condition. If no improvement occurs in two or three days, operate. If the subjective symptoms improve, while the objective symptoms get worse, stop the opium. If the patient then gets worse, operate.

The operation for ileus is much more dangerous than ordinary exploratory laparotomy. This is because the condition of the patient is bad, the intestines protrudes from the incision, and much time is lost in looking for the point of obstruction.

To cleanse the peritoneal cavity, only a salt solution and sterilized gauze mops should be employed. Antiseptics are dangerous.

Statistics are unreliable, as only the favorable cases are usually reported.—*Deut. Med. Zeit.*

THE ETIOLOGY OF CHEYNE-STOKES RESPIRATION.

Dr. M. A. Boyd read a paper on the etiology of Cheyne-Stokes' respiration, in which he reviewed all the physiological explanations of this phenomenon offered by writers on the subject since Stokes' time to the present day. He particularly pointed out the very rational explanations offered by Traube and Filehene, who regarded the respiratory derangement from the altered nutrition of the respiratory-centre point of view; and of those of the Dublin School, including Hayden and Little, who regarded it primarily from the cardiac point of view, and complimented the Dublin School as offering by far the best evidence, both clinically and pathologically, in explanation of the phenomenon. Having alluded to the marked rhythmical irregularities between the heart pulse and respirations in this affection, Dr. Boyd drew attention to a point which heretofore in the literature of the subject, so far as he was aware, had not been previously alluded to—namely, that the latter portion of the forced respiratory phase of the Cheyne-Stokes' cycle is chiefly an expiratory one, in contrast to the first portion of it, which is an inspiratory one; and that this forced expiration had a most important bearing on the weak ventricles of the heart, by helping them to squeeze the blood on the one side into the pulmonary artery, and on the other into the dilated and inelastic aorta. In proof of this he exhibited sphygmographic tracings showing that it was only during this expiratory portion of the respiration that arterial tension was raised in the arteries, and that this tension continued through the apnœal period following, during which time the respiratory centre was fully supplied with arterial blood and the weak and degenerated left ventricle resting. He regarded the apnœal period, during which time respiration was suspended, as only an effort on the part of the higher automatic centres to rest a heart the ventricle of which is either too feeble to charge an arterial system, the aorta of which may be dilated and inelastic, or the vaso-motor control of which may be defective, and whose own blood supply may be rendered insufficient in consequence, and its nutrition enfeebled. After the intrinsic muscle of the heart has been fed by this increased arterial tension of the expiratory and apnœal periods, forced inspirations begin again, and the heart contractions are stronger, but they fail to fill the dilated aorta, until the forced expirations, by making pressure on the ventricles, come to their aid again. The most typical and pronounced forms of Cheyne-Stokes' respiration were to be met with in alterations of the heart and aorta produced by degeneration and disease. The

form of it met with in cerebral disease or injury, and in apoplexy and uræmic coma, without any primary engagement of the heart, he regarded as due to direct interference with the respiratory centre in the medulla, either by pressure or poisoned blood, and the phases of it were never so well marked as in those cases of the affection depending primarily on alterations in the heart. Owing to its dual origin in this way comes the differences of opinion as regards its pathology. As regards its treatment, Dr. Boyd found so much improvement following the inhalation of oxygen in all the cases where disease or degeneration of the heart produced it, that he urged a trial of this remedy in all such cases, and ventured to suggest, from his experience of the remedy, it should be tried not alone in this affection, but in all cases where degeneration of the heart existed from any other cause.—*Lancet.*

SURGERY.

ON THE TREATMENT OF CHRONIC INDOLENT ULCERS.

Chronic ulcers are generally situated over the tibia, about the middle or lower third of the inner aspect of the leg. They are "callous" ulcers, with thick, hardened, almost cartilaginous borders and edges, with a sunken, pale and dusky base; there is absence of florid granulation, and the secretion is then and often offensive. The indications for treatment of these ulcers, whose vitality has always been greatly compromised by chronic inflammation, are the following: To subdue inflammation and stimulate the cells of the part to new activity; to restore the normal circulation; to soften the indurated tissues which oppose cicatrization; to combat and destroy micro-organisms, which luxuriate in the part and keep up inflammation and necrosis; to remedy any existing dyscrasia, and fortify the constitution of the patient.

We shall not presume, in an article which must be brief, to take up these indications in their order; any mode of treatment to be successful must aim to more or less meet them all. Sometimes granulation action is best promoted by stimulating astringent and antiseptic lotions, such as the *red wash* (sulphate of zinc, two grains; rose water, one ounce,) *liquor acidi carbolici* (a two per cent. solution,) the *lotio nigra*, solutions of salicylic acid (one drachm to the pint, of tincture of myrrh (one drachm to four ounces of water,) of nitric acid (one drop to the ounce of water,) etc. "In a healthy sore," says Dr. W. Alexander, "where there is no mechanical obstruction to cicatrizations, the lotion most rapid in producing the desired effect is chloride of zinc." An antiseptic chloral lotion (chloral, one drachm; water, four ounces) is highly commended by Dr. Dowse, of London.

In many cases which are not too far advanced, the mere fact of keeping out offensive microbes will often cause a healing process to start; here the use of a corrosive sublimate lotion, of dry calomel, as a local application, or simply dusting the sore with iodoform, and covering with antiseptic gauze and a simple roller, will be at once attended with the formation of healthy granulations and a contraction of the margins of the ulcer.

Should indolent ulcers ever be poulticed? Theoretically, poultices might be expected to fulfil several important indications, and instances will repeatedly occur when they will prove beneficial. Sometimes the indolent ulcer is irritable and needs soothing, and a linseed poultice is the best application; and always where it is desirable to produce active determination of blood to the part, and increase the formation of vessels and cells, poultices may advantageously be used, though the continuous warm bath, as recommended by Billroth, is even better. We thereby obtain an artificial swelling and softening of the dry, hardened borders of the ulcer. Zeis, who has often employed the warm-water bath in callous ulcers of the leg, also recommends this treatment as one of the most efficacious in such cases.[1]

The indolent ulcer generally refuses to heal on account of mechanical obstacles to cicatrization; the blood-vessels of the part are distended and toneless, if not atheromatous; the tissues are œdematous and swollen; the veins, it may be, are varicose. Here pressure judiciously applied is the indispensable means of cure. In all text-books a prominent place is given to a system of strapping, first devised by Baynton in the latter part of the last century; the adhesive strips are cut from an inch to an inch and a-half in width, and long enough to extend about three-fourths around the limb, each band being so arranged as to overlap that which is below it, and drawn so firmly as to afford uniform support to the affected surface.

It was found that serious disadvantages attended this mode of treatment. The dressings had to be frequently removed, otherwise the pent-up discharge became very offensive. Dr. J. Gordon Black several years ago pro-

[1] Billroth, "Surg. Path.," p. 399.

posed a modification of the Baynton dressing, which has been quite successful; certainly, for varicose ulcers, no treatment could be better. For plaster, he uses the *emplastrum saponis.* This is first warmed by being passed through hot carbolic-water. "The sore, after being washed clean by the patient, is then saturated with weak solution of carbolic acid and the straps applied. The pieces of plaster should be two inches broad, and long enough to overlap four inches after passing completely around the limb. They should be applied after the manner of a 'Scot's dressing,' from about three inches below the lowest diseased surface to about the same distance above the highest. In their adjustment it is important to use no compression, but simply to lay them down evenly, so as to fit the limb accurately, and leave no creases in the plaster. Should pain be produced, the strap has been improperly applied, and should be at once removed. The bandaging of the limb lightly and carefully from the toes to the knee finishes the dressing. The patient may be told to return at the end of a week, when, on removal, the plaster will show only a slight moisture, instead of the profuse and offensive discharge seen when no antiseptic is used."[1]

Under this treatment, says Dr. Black, the horny edges of the callous variety quickly disappear, without recourse to such a dangerous excitant as blistering (a method recommended by Home, Cooper, and other of the older surgeons). In eight or ten dressings, even very extensive ulcers may be healed by strapping.

Mr. Nourse, a surgeon of Brighton, reports great success from strapping and bandaging, according to this method.[2]

On this principle (that of keeping up uniform pressure) it has been proposed to treat indolent ulcers by means of sheet leads, as in the plan described by Dr. Atkinson in the *Practitioner*, May 1879. A piece of sheet lead is moulded to the leg, and kept on by an ordinary calico bandage. The size of the lead should be sufficient to cover the sore completely and lap a little over the whole skin; the edges and angles should be well rounded, so as not to chafe and irritate; it should be about an eighth of an inch in thickness, and moulded very accurately to the shape of the leg, so as to allow of no indent being apparent on the surface. After it has been carefully fitted the leg should be carefully bandaged from the toes upward. The ulcer is uncovered night and morning, and a little weak sublimate water allowed to trickle over it.

Dr. Watson, in the *Boston Medical and Surgical Journal,* utilizes sheet tin for the same purpose. The dressing is known at the Boston City Hospital as the "tin dressing," and its method of application is as follows: The ulcer and surrounding surface are soaked in corrosive sublimate, 1 part to 4000, and thoroughly cleaned. A bit of protective is then placed on the surface of the ulcer, extending a little beyond the margins of the ulcer; oiled silk will answer the purpose. The tin, made to fit the surface on which it is to lie, is then placed on the protective, and the whole, as well as the surrounding tissues, covered with a dry corrosive sublimate gauze dressing, which is held in place by an evenly applied bandage, extending from the toes to the knee. Ulcers which have been for a long time lagging, will often take a fresh start under this dressing.[1]

The treatment of indolent ulcers, and especially varicose ulcers, by the Martin rubber bandage, deserves mention, as being a very popular and very successful method. This treatment consists in applying a solid rubber bandage to the limb affected before the patient gets out of bed in the morning. It is not necessary that there should be any application between the ulcer and the bandage. The bandage is put on with just the requisite degree of tightness to prevent its slipping down. It is kept on all day, and only taken off at night on going to bed, when it is washed in warm water and hung up to dry. The ulcer is then covered with some simple dressing, which is kept in contact by a few turns of an ordinary roller.

Since the publication, about fifteen years ago, of Dr. Martin's memoir, "On the India-Rubber Bandage for Ulcers and other Diseases of the Legs," this mode of treatment has come into very general use everywhere, and a whole volume could be published made up of clinical reports and articles that have appeared on this subject alone. Surgeons like Clutton, of St. Thomas's Hospital, are enthusiastic in their praises of this mode of obtaining a uniform curative pressure; it is, says Clutton, "the best method yet devised of applying an old therapeutic principle." It is, of course, understood that this treatment is adapted to simple rather than specific ulcers; a syphilitic sore will demand the specific treatment in addition to the local.

[1] "Braithwaite's Retrospect," Part lxviii. p. 195.

[2] *Brit. Med. Journ.*, May 31, 1873.

[1] *Medical News*, October 15, 1887.

But there are chronic ulcers which cannot be made to heal by any amount of strapping or bandaging; here multiple incisions have been recommended, by Dr. F. Spaeth, in the *Practitioner*, May, 1888. This writer affirms that the lateral incisions and the circular incisions around the margin, recommended by Weber and Nussbaum, have generally proved unsuccessful. (This has also been the experience of Billroth, Verneuil, Nélation and others.) His method is more radical still. The entire ulcer is divided lengthwise by a deep incision, extending far into the healthy tissue. Cross incisions are then made through the callous tissue into the healthy at intervals of about three-quarters of an inch. The incisions must go through not only the skin, but the underlying fascia; the wounds must gape widely. The bleeding, often profuse, must be stopped with tampons; and the whole wound is then done up with iodoform dressings. "When, after eight to fourteen days," says Dr. Spaeth, "the dressing is changed, the difference in appearance is very marked. Healthy granulations are springing up in abundance from the gaping incisions, and soon cover the whole surface, reaching the level of the surrounding skin, from which the growth of new epidermis is seen to advance rapidly. . . . The advantage of this method is that highly vascular healthy parts are enlisted in the healing process of granulation, and thus not only the wound but the resulting cicatrix are under more favorable conditions. It might be expected, and facts confirm the expectation, that this cicatrix is far stronger and more resistant than the thin covering which may occasionally be obtained from scanty granulations, after the use, perhaps, of every means in the surgeon's armamentarium, and with great difficulty at that."

We have only space to mention without comment an ingenious device of Dr. Philip Cowan, which he calls "A New Method of treating Ulcers," and which is based on the fact that an ulcer is "a local asthenia of the skin and parts beneath," "a local tendency to degeneration and death." Availing himself of the property of absorption inherent in ulcerated surfaces, he would *feed the ulcer* with such nutrient substances as eggs and milk and flour, applied in the form of a paste to the part. He claims that his theoretical provisions have been proved to be scientifically well established by the results of practice, and gives reports of eighteen cases where the ulcers were "fed" till cured.[1]

Skin-grafting was introduced in 1869 by Reverdin, of Paris. It has proved to be a most valuable means of cure in many cases. The grafts are generally taken from the anterior aspect of the forearm, and include only the cuticle, with the rete mucosum and the apices of the papillæ. The grafts are placed about half an inch apart, and are confined by pieces of gutta-percha tissue and strips of plaster. With due care, it is quite easy to get a number to take, and thus there are provided "new centres of cutification," which also have the power of exciting cicatrization at the margin. Brilliant results have been obtained by this mode of treatment, which ought always to be tried in bad, intractable cases.

The constitutional treatment of indolent ulcers must be adapted to the cachexia accompanying or producing them. Some patients need only a general tonic and reconstituent treatment; others are gouty, tuberculous, or syphilitic, and demand the proper remedies for those dyscrasiæ. He will have the best success in treating chronic ulcers who best masters the various etiological factors concerned in their production.—*Therap. Gaz.*

GYNÆCOLOGY.

CASE OF HÆMOGLOBINÆMIA AND HÆMOGLOBINURIA FOLLOWING INTRAUTERINE USE OF CARBOLIC ACID.

Richard Krukenberg reports the case of a woman, twenty-eight years old, who had borne three children and was under observation for threatened abortion. After a chill, an embryo of two months and part of the membranes were cast off. The patient was pale, completely conscious and without special complaint. The pulse was 96 and regular, respiration not accelerated; the heart showed signs of a compensated mitral insufficiency. Chloroform was given, and the uterus curetted; about one and a half tablespoonfuls of membranes were removed, one little piece being greenish-gray. The uterus was then washed out with a 2.7 per cent. solution of carbolic acid, Olshausen's modification of Bozeman's catheter being used. The eyes of the catheter became

[1] "Braithwaite's Retrospect," Part lxvii. p. 167.

plugged with particles of tissue. About one quart and a quarter of the fluid was injected, when the pulse became small, and then ceased. The douching was immediately stopped, the uterus expressed bimanually, and the woman, who was pale and cyanotic, placed horizontally. The pulse, when it returned beat 100–112 per minute, two strong beats being followed by a weak one. Artificial respiration was necessary. The pupils were small and did not react; the extremities were flaccid, without tremor or spasm. The lungs become œdematous. After the deep coma had lasted two hours, it yielded gradually to the employment of powerful analeptics and irritants to the skin; but the intellect remained clouded. The patient muttered unintelligibly, was restless, breathed stertorously, and presented a pale, cyanotic face, covered with cold sweat. Two hours after the douching the bladder was emptied of five fluid-ounces of urine, dark blood-red in color, resembling raspberry juice. It smelled of carbolic acid, and after being filtered had a specific gravity of 1021. The fluid contained albumin, peptone, and 0.262 per cent. carbolic acid, estimated as tribromphenol in the acidulated distillate of the urine. The normal quantity of carbolic acid in the urine, according to J. Munk, is 0.0034 per cent. Spectroscopic examination demonstrated the presence of oxyhæmoglobin, with characteristic absorption bands in yellow and green. The reaction of the fresh urine was acid, the specific gravity when unfiltered, 1024. On boiling, and with addition of acetic acid, there was a blackish-brown precipitate, which after standing a day filled one-third of the glass. Hæmin crystals were obtained from the sediment, and Heller's test for blood gave a positive result. The sediment also contained red blood-cells, epithelium, no casts, but golden-yellow clumps, partly firmly granular and partly homogeneous.

About four hours after the abortion the patient regained consciousness, complained of great weakness, and with difficulty expectorated a profuse, frothy mucus. During the night she had a brown stool, and urine involuntarily passed. She was delirious, and so restless that the moist pack ordered for her had to be removed. Toward daybreak it was noticed that she was very much jaundiced. The urine (one-half to three-quarters of a quart) was raspberry-colored, but unfortunately was thrown away. On the following day, the temperature was 98°, the pulse 110; there was sensitiveness over both kidneys and the spleen; the spleen was enlarged. The patient complained of headache, great weariness, loss of appetite, and frequent desire to urinate, with pain on micturition. A day later considerable swelling of the liver was detected. The jaundice continued, with the diffuse catarrh of both lungs. There were slight chills. The jaundice slowly disappeared, the catarrh persisted, the swelling of the spleen increased, while signs of peritonitis and of œdema were entirely absent. The urine contained a few red and numerous white blood-cells, much-clouded kidney epithelium, very few epithelial casts, but extraordinarily numerous and large hæmoglobin cylinders, yellowish-red to golden-brown in color. The patient died in coma, following a uræmic attack. The highest temperature observed was 102.1°. The pulse shortly before death remained under 100.

The following symptoms were prominent: 1. Oliguria (seven ounces of urine in twenty-four hours as the maximum), which increased almost to complete anuria. 2. Complete anorexia; violent vomiting, which made nourishing in the usual way impossible; the vomitus smelled decidedly ammoniacal. 3. Brownish, scanty discharge of foul odor from the vagina.

The autopsy confirmed the clinical diagnosis. The author reviews other cases that have been reported, and expresses the opinion that the symptoms produced were due to a specific toxic action of the carbolic acid, which decomposes the hæmoglobin and the red blood-cells. Krukenberg, nevertheless, concludes that when the necessary precautions are used, carbolic acid is the most serviceable intra-uterine antiseptic, and the one to be preferred to all others.—*Zeitschrift für Geburtshülfe und Gynäkologie*, Bd. xxi., Heft 1.—*News.*

UTERINE CURETTE AND ANÆSTHETICS.

Dr. Geiel (*Nouvelles Archives d' Obstet. et de Gynœcol.*,) does not consider that chloroform is necessary, or even advisable, for the operation of scraping the endometrium in cases of endometritis. He maintains that the proceeding is absolutely safe, providing that the manipulations are skilful, and adequate precautions against sepsis be taken. Cicatrices and atresia of the cervix need never occur, and hæmorrhage should cease directly the operation is performed. Dr. Geiel dilates the cervix with a tupelo tent. Within thirty-six hours the patient will be ready for the curette. The use of that instrument causes but little pain, and the little which it does cause is necessary for the

detection of the most diseased spots on the endometrium. The patient is placed in the correct position and the tender spots are marked out by the touch of the sound. Then a twenty per cent. solution of hydrochlorate of cocaine is applied to the most tender parts, while the remainder of the uterine cavity is painted with a ten per cent. solution of the same compound. The anterior lip of the os is then seized by means of a volsella, and held by an assistant, so as to keep the uterus fixed and well drawn down during the operation. The endometrium is dried with wool and then carefully scraped, especially at the tender points. The characteristic grating sound (*cri utérin*) should be heard over every part subjected to the curette, as it indicates that the diseased material has been thoroughly scraped away. Lastly, the uterus is washed out with a 0.05 per cent. sublimate solution. This washing is better than swabbing (*ecouvillonage*). The after treatment consists in the administration of antiseptic vaginal injections, and in the introduction of iodoform-glycerine tampons. With the above precautions the curette may be safely used in cases of pure endometritis.

OBSTETRICS.

A CASE RELATING TO THE INFLUENCE OF MATERNAL IMPRESSIONS UPON THE FŒTUS.

Dr. R. Osgood Mason, in an article in the *Medical Record*, affords some interesting reading: The *Record* for May 18, 1889, contained a communication from me intended to show that physicians and others, who believe that strong impressions made upon the mother during pregnancy may have an influence upon the fœtus *in utero*, even to the extent of causing marked physical changes, need not necessarily be believers in *witch broth* and such like supernatural things, but may be well-informed, thoughtful, and even scientific people. While preparing that communication a newspaper item fell under my observation referring to a family of albino children in Harrisburg, Pa., presenting some interesting features bearing upon the subject in hand, and having the authority of the attending physician, Dr. M. K. Bowers, of the same city. I at once wrote to the doctor in regard to the matter; he kindly replied, and I found in him a most interested and intelligent observer and correspondent.

The following facts were elicited which, with the doctor's permission, I have prepared for publication.

Two years ago, when our correspondence commenced, the family referred to consisted of father, mother, and three albino children. The father of the children is a very dark-skinned man with black eyes and jet-black hair; the mother is not quite so dark, but has dark hair and dark-blue eyes. The grandparents all have dark complexions and dark hair, and the family, as far back as its history can be traced, is entirely free from freaks or abnormalities of any kind.

Two years previous to the birth of the first albino the mother gave birth to a perfectly normal, healthy child having dark eyes and very black hair. This child died just previous to her next pregnancy.

With the second pregnancy everything went on as usual until near the beginning of the second month, when one day she unexpectedly received a small box by express from a friend in Philadelphia. She was quite ignorant of the contents of the box, which, however, was at once opened in her presence and was found to contain a large, handsome, perfect albino rat. As soon as she saw it she became nervous and declared that the sudden impression made upon her would show itself upon her child.

The rat, however, was tame, and was at once domiciled in the house. It became a general pet in the family, the pregnant woman herself also becoming very fond of it, often playing with it and holding it in her hands. A short time before her confinement the rat was accidentally killed, an incident which caused her considerable annoyance and sorrow.

A few days later the doctor was called to the confinement, which resulted in the birth of a fine boy baby, but a perfect albino. The mother, when informed of the fact, did not seem at all surprised, but said at once, "I knew it, I told you so. It was the rat—oh, that rat!" However the boy grew beautifully and became a great pet both at home and abroad, "the mother herself becoming *wonderfully* attached to him."

The mother soon became pregnant again, and informing the doctor of the fact, she remarked that she had made up her mind to have a pair of albinos. Her expectations were realized, and in due time she was delivered of a fine girl baby, also a perfect albino.

Upon the occurrence of her next pregnancy she remarked that this ought to be a black-haired baby, but she feared she would

be disappointed. Her fears proved well-founded, and her pregnancy resulted in another perfect albino girl.

So, dating from the white rat episode, we have three perfect albino children, concerning whom the doctor writes: "The children are remarkable for their health, never having been sick, general activity, and unusual intelligence. They are much better specimens of the albino type than any found in museums or circus shows. They have snow white hair, eyebrows, and lashes, the hair being remarkably fine and soft. The eyes are extremely sensitive to light, and when exposed to the sunlight or a bright artificial light they keep them closed; but in a subdued light or on a cloudy day, they are wide awake and have very acute vision, being able to see the smallest objects, even when the room is quite dark. The sclerotic is of a dull white, a distinct bright pink (almost red) line binding its juncture with the cornea, the pupil is of a slightly darker shade of pink. The eyes are constantly in motion, never resting more than a moment upon any one object. The two older children are extremely bright and active, and the new-comer, now four days old, promises to rival her distinguished brother and sister. She is an unusually fine baby."

Such was the state of affairs in the albino family in May, two years ago.

During the second week of April last I received another letter from Dr. Bowers, from which I gather the following interesting facts. The albino children were all living and in excellent health; furthermore, on Sunday morning, April 5th, the doctor was again called to attend the mother in her confinement, when she gave birth to a perfect and vigorous twelve pound boy, with black hair and dark-blue eyes, as utterly unlike the albinos as it was possible to imagine. The three former children are, if possible, more pronounced albinos than they were two years ago, and the family, as at present constituted, presents a most singular and interesting group.

The doctor then goes on to say: "This last dark-haired, normal child appears to be a striking example of will-power exerted by the mother. She has been under my care continually, and I know that it has been her one chief desire to have such a child. She was exceedingly anxious to become pregnant, and when she was convinced that such was the case she sent for me, and during our conversation made this remark: 'Now, doctor, keep your eye on me, for I am sure it is all right, and this time it will be a black-head!' She at once sent her albino children away to her mother's house, to remain during her pregnancy, and the husband tells me that her one constant song and desire was for the dark-haired baby. She talked of it constantly, she even talked of it in her sleep." When called to attend her she at once said to the doctor, "Now I am ready for my dark baby."

The doctor remarked that the desire on the part of his patient for a dark-haired child was not merely the whim of an ignorant or illiterate person; on the contrary, she was well educated, generally intelligent, and an unusually brilliant woman. Her parents were educated people—her father at present holding a prominent position in one of the offices of the State Government—and that her desire was accompanied by a very strong faith and intelligent effort for its fulfilment.

The case is simply one, and a strong one, bearing on the question of the possible effect of maternal impressions upon the fœtus *in utero*.

The case sums up as follows: Parents both dark—one *very* dark, to whom is born, as might naturally be expected, a dark-complexioned child.

Early in the second pregnancy of the mother she is surprised and made nervous by the sudden and unexpected appearance in her family of a large, handsome albino rat. She affirms that it will have an effect upon her unborn child.

Albino number one is born. She becomes exceedingly fond of it; its peculiar face is ever before her. She is not averse to another similar child, but desires it.

Albino number two is born. The next pregnancy she hopes may terminate by the birth of a dark-haired child; but she is surrounded by the same influences, and the same models are before her. She fears disappointment, and she experiences it.

A third albino child is born. Upon the occurrence of her next pregnancy she is thoroughly aroused, and is influenced by a peculiarly strong wish for a dark-haired child. She affirms that it will be so. She exerts her will to promote her wish. She removes from her sight the models which she does not wish should influence her. She directs her mind constantly to the ideal of a dark-haired child. She dreams of her dark-haired child and speaks of it in her sleep—an important fact as indicating unusual susceptibility to impressions. She feels that she will not be disappointed, and she is not. A perfect dark-haired child is born.

The "coincidence" man is abroad, but he

has a sallow and antiquated look, and along with his friend, the "unconscious muscular action" man, seems to belong more properly to the early part of the century. Experimental psychology is bringing to light many important facts showing mind producing physical effects beyond the limit of actual nerve supply. Why not in cases like that above cited? I think we have occasion to thank Dr. Bowers for his interesting case in point.

PÆDIATRICS.

RARE COMPLICATIONS IN DIPHTHERIA.

Dr. Julius Schwalbe, in an interesting article on the above subject, appearing in the *Deutsche Med. Wochenschrift* but recently, the following case, among others, is cited. A male child, two and one half years old, had had tracheotomy performed, on account of diphtheritic laryngitis. On the fourth day following the operation, the wound became diphtheritic, and three days later a hæmorrhage of the wound occurred, which proved uncontrollable. The subsequent autopsy revealed no satisfactory cause for the hæmorrhage, other than a possible gangrenous process effecting the vessels in the immediate vicinity of the wound.

Among the histories of 2500 cases of diphtheria occurring in the Friedrichshain Hospital, Dr. Schwalbe was only able to find the records of three similar cases, and in these, as in his case, the source of the hæmorrhage could not be satisfactorily determined. The following is another case of hæmorrhage. The patient was a boy nearly four years old, who, five days after the performance of tracheotomy, while confined to his bed, was suddenly seized with a most violent hæmorrhage from the trachea. The little patient, who as it was, was very anæmic, was at once raised up by his feet and energetically shaken. At the opening of the tube a bit of false membrane made its appearance, which, upon removal, proved to be a cast of the bronchi, considerably ramified. Upon the removal of this membrane, the hæmorrhage ceased as suddenly as it had appeared. Schwalbe is of the opinion that in this case the hæmorrhage was probably caused by a rupture of numerous superficial capillaries, due to the forcible expulsion of the membrane.

Schwalbe has compiled the following table illustrative of the various causes of hæmorrhages consecutive to diphtheria.

A. *External Hæmorrhages*:

1. In gangrene of the nose and pharynx—*Cause*, general septic process, and narcotic degeneration of the parenchyma.

2. In diphtheritic infiltration of the tracheotomy wound—*Cause*, a continuation and spreading of the necrotic process to the neighboring vessels; or,

3. In consequence of a rupture of some vessel in the immediate vicinity of the tracheotomy wound (the ætiology of this theory is uncertain.)

4. In consequence of a rupture of some vessel by the canula.

B. *Internal Hæmorrhages* from the tracheal or bronchial mucous membrane.

1. In consequence of a decubital ulcer.

2. In consequence of an opening of the vessels, due to the removal of the diphtheritic membrane; especially probable in cases where a hyperæmic condition of the lungs exists.

3. In consequence of simple hyperæmia of the lungs (especially after bronchitis fibrinosa.)

In a second portion of his article, Dr. Schwalbe also cites cases illustrating other unusual complications in diphtheria, among which may be mentioned emphysema of the skin with sub-pleural emphysema, and double pneumo-thorax.

NEW METHOD OF TREATING GRANULAR CONJUNCTIVITIS IN CHILDREN.

Sattler's method (*Journ. de Méd.*) consists in everting the upper lid, as is usually done, and then by means of a special form of forceps seizing it so as to completely disclose the conjunctival cul-de-sac. The mucous membrane should then be deeply scarified, after which the submucous tissue should be thoroughly curetted in order to remove all colonies of microbes which may be there. The wound is then to be washed with a one to five hundred solution of sublimate.

Abadie has used this method in many cases with excellent results. In place of a steel curette he employs a nail-brush with very short and stiff bristles. The mucous membrane having been lacerated, he then rubs it briskly with the brush dipped in the one to five hundred solution of sublimate. For a few days afterwards he subjects the lids to eversion and washing with the sublimate solution. Many cases were cured by this method which had long been treated unsuccessfully with cauterization of sulphate of copper.

Trousseau, in criticising this method, fears that the curetting might be followed by entropium and trichiasis with retractile scars.—*Archives Pædiatrics.*

HYGIENE.

THE INFLUENCE OF TOBACCO UPON THE DIGESTIVE FUNCTIONS OF THE STOMACH.

Dr. Ydam Pouchkine, of Russia, has recently concluded an interesting series of experiments relative to the influence of tobacco upon the digestive functions of the stomach, as well as upon the acidity of the urine. His experiments were made upon seven different subjects, all in robust health, and none of whom were addicted to the habitual use of tobacco in any form. At first the effect of tobacco upon the gastric juices was observed, especially in regard to the motive power of the stomach, and also its absorptive power.

In each case, for three days, the author carefully examined the gastric juices of his subjects by the known methods, its motility by salol—according to Ewald's method—and its absorptive power by Zweigel's method with the iodide of potassium.

After this, the second portion of the experiment was carried out, and again, for three consecutive days the various functions of the stomach accurately tested; only during this second period each subject smoked twenty-five cigarettes a day.

From the results of these experiments, Pouchkine is enabled to draw the following conclusions:

1. Tobacco increases the quantity of the gastric juice, while it diminishes its acidity.
2. The quantity of free hydro-chloric acid in the stomach is materially lessened by the influence of tobacco.
3. In proportion to the diminishing of the quantity of free hydro-chloric acid, the digestive functions of the stomach are also diminished.
4. Tobacco occasions similar symptoms as those caused by the ferments.
5. The modifications of the gastric juice, caused by the use of tobacco, lasts for some time.
6. Both the motility, as well as the absorptive power of the stomach, are increased by tobacco.
7. Tobacco exerts no influence upon the acidity of the urine.—*Wratch.*

EPIDEMIC NEURALGIAS IN AUSTRIA.

For the past thirty years, Professor Benedikt, of Vienna, has been making a careful study of the epidemic supraorbital neuralgias which occur in that city in winter and spring. Usually the symptomatic picture is one of a peripheric neuritis. This year the number of victims has been very large, and the apparent epidemic nature of the disease most manifest. The majority of cases occur among the people living near the banks of the river Donau, or near the river meadows. While the nature of the spread of the disease would seem to indicate its infectious character, it is nevertheless, not infectious; neither is it of a febril origin, nor malarial, for almost without exception it is unaffected by the usual antipyretics, such as quinine, antipyrin, or antifebrin. Again, there is an entire absence of fever, and also of any enlargement of the spleen.

The specific treatment consists in the exhibition of iodine salts, particularly iodide of soda, in doses of one gramme daily. It seems also, that the addition of twice this quantity of salicylate of soda, considerably increases the efficacy of the former drug.

A second specific treatment consists in galvanization. In the peripheric forms of the disease, the one electrode is placed at the back of the neck, and the other over the seat of the trouble. In the excentric forms of the disease the sympathetic nerve is galvanized.

In patients constitutionally faulty, the disease not infrequently assumes a chronic form.—*Wiener Med. Wochenschrift.*

AN EASY METHOD OF FEEDING PER RECTUM.

Mr. Y. M. Jones-Humphreys, L. S. A., writes (*Lancet*, February 14th, 1891): Some months ago, having to treat a bad case of gastric ulcer by rectal feeding, etc., I devised an apparatus consisting of a small funnel, a piece of elastic tubing ½ inch in diameter, 1½ feet long, about 4 inches of glass tubing (by which the descending fluid can be watched), and joined on to this an ordinary flexible catheter. The atmospheric pressure is sufficient to send any fluid into the rectum, and I have never noticed any return of the fluid, absorption being slow but efficient. The instrument is an improvement on the old enema apparatus in use. The claims for this method are: (1) It is extremely simple, the patient being able to pass the catheter into the bowel without ex-

periencing any pain or unpleasantness: (2) It is cheap and easily made: (3) After once being shown, the most inexperienced person can use it, and thus we can be sure our patient will have small quantities of nourishment at frequent intervals: (4) The fluid is slow in its passage, and thus nearly the whole quantity becomes slowly absorbed. In any case requiring rectal feeding, I venture to hope that my professional brethren will find this simple method of use to them, and a source of comfort to their patients.—*Hospital Gazette.*

COFFEE: ITS USE AND ABUSE.

A paper on this subject, by Dr. I. N. Love, concludes as follows:

1. The world has, in the infusion of coffee, one of its most valuable beverages.

2. As a prompt diffusible stimulant, either by the stomach or by injection into the rectum, it is in all cases of shock preferable to alcohol.

3. It is antagonistic to malaria and specially destructive to the typhoid bacillus and cholera germ, and for this reason it is an admirable remedial agent in these conditions, both as a direct stimulant, and antiseptic and an encourager of elimination.

4. One of its chief advantages in health and disease is in the fact that it aids in securing that psychical satisfaction which is conducive to hope, comfort, good digestion, great power of resistance and rapid recuperation.

5. In season, it supports, tides over dangers, helps the appropriative powers of the system, whips up the flagging energies, enhances the endurance, but is in no sense a food, and for these reasons, and many others, it should be used temperately, as should all of nature's benign gifts.

6. In excess, it is even more dangerous than alcohol, for it is not, like the latter, a nutrient, nor is the effect of its excessive use so apparent or disrespectable.—*Annals Hygiene.*

MEDICAL CHEMISTRY.

TESTING FOR SUGAR.

Hunkiarbeyendrian adds salol to the list of substances which impart to urine the property of reducing the oxides of copper, silver and bismuth in alkaline solution. The urine of persons to whom salol has been administered, furnishes, when tested with Fehling's solution, a precipitate of the red oxide of copper, the quantity varying with the amount of salol absorbed. If such urines contain at the same time sugar, the polariscopic test is also subject to error, since urines containing derivatives of salol polarize to the left; the results obtained are therefore too low.

To distinguish, in urine, sugar from the derivatives of salol, the following process is recommended: A tube of the capacity of fifteen cubic centimetres, is half filled with urine previously treated with basic acetate of lead. To this is added five centigrammes of hydrochlorate of phenyl-hydrazin and twenty centigrammes of sodium acetate. The liquid, which assumes a yellow color, is heated in the water-bath to 100° for half an hour, and then allowed to cool, when the precipitate formed is examined microscopically. If due to derivatives of salol, the precipitate is amorphous; if to sugar, it is composed of small, silky crystals of phenylglucosazone, which are at times grouped into tufts.

A more rapid process, which does not require the employment of the microscope, is the following: To 200 cubic centimetres of urine, there is added one gramme of sulphuric acid and about 50 cubic centimetres of ether free from alcohol. The mixture is shaken for several minutes, then allowed to stand awhile. The upper layer, which contains the derivatives of salol, is evaporated in a porcelain capsule, the residue thus obtained dissolved in a little water, and the solution tested with a few drops of a solution of the perchloride or persulphate of iron. A violet coloration is produced in the presence of derivatives of salol. The lower layer of liquid is treated with basic acetate of lead, and, after filtration, tested for sugar by the ordinary methods. Non-saccharine urines containing derivatives of salol, when treated in this manner, have no action on metallic oxides, or on the rays of polarized light.

Jollis considers that a sharp distinction exists between glycotic and diabetic urines. The former contain but mere traces of sugar, about 0.4—0.5 per cent., and otherwise are not characterized by abnormal chemical and physical properties. The diabetic urines, on the other hand, have a high density, a pale-yellow color, a less quantity of uric acid than normal urine, and contain acetone, or aceto-acetic acid, or acetic acid. Sugar usually occurs in them in considerable quantities, although this is not always the case. A new method, namely, to paint a visiting card first with copper sulphate solution, and, after drying, to apply the suspected urine with a

match, dry and heat, which has recently been proposed by von Becker, is considered wholly untrustworthy by the author. Trommer's method, and Seegen's modification of the same, are also considered valueless by the author. Böttger's bismuth re-agent and the phenyl-hydrazine test are found by him to be trustworthy. With Böttger's bismuth re-agent, 0.08 per cent. of sugar may be detected, and if the urine be first boiled with a solution of sodium chloride the delicacy is heightened, 0:01 per cent. being then detectable. At least fifty cubic centimetres of urine must be employed to five cubit centimetres of Nylander's re-agent, and should not be boiled for more than two minutes. The presence of such substances as rhubarb, kairine, oil of turpentine, quinine, arsenious and salicylic acids, sulphur, mercury salts and iodides, should be avoided. In the case of considerable quantities of uric acid, it is to be observed that the brown coloration produced by it remains constant, whereas that produced by the presence of sugar becomes continually darker. The phenyl-hydrazine test enables 0.015—0.038 per cent, of sugar to be detected, the delicacy being the greater, the less the amount of reducible substances present. At the same time crystals, very similar to those of phenyl-glucosazone, are formed with glycuronic acid. The latter are, however, not so fine, and have not the same striated arrangement as those of phenyl-glucosazone.

Hirschl considers the phenyl-hydrazine test a perfectly trustworthy one. If the urine gives typical needles of phenyl-glucosazone, it certainly contains glucose. It is essential, however, that the test-tube should be allowed to remain one hour in the water-bath. If this is done, the precipitate caused by glycuronic acid, if this substance is present, it is wholly amorphous, and easily distinguishable from phenyl-glucosazone. Levulose cannot be distinguished from dextrose by this test, but only by the polarimeter. Lactose, which has been found in the urine of nursing women, furnishes needle-shaped crystals, which are about ten times the width of those of phenyl-glucosazone, and do not show the same orderly arrangement. Their melting point is 200°. Maltose gives a precipitate, which occurs in yellow tables, melting at 82°.—*Boston Med. Surg. Jour.*

NEWS AND MISCELLANY.

TO THOSE WHO WEAR FALSE HAIR.

The English consul at Canton says that eighty thousand pounds of human hair have been exported from that city during the past year, and that it comes mainly from those who have died of contagious disease, mendicants and criminals.—*The Physician and Surgeon.*

THE NASTIER THE BETTER.

Turpentine, treacle, and castor oil,
Add some creosote, gently boil;
Sift iodoform into the stuff;
Add some glycerin (quantum suff.)
Set it aside for some time to cool—
That's the medicine for boys at school.
—*Medical Press.*

HOW IT WORKS.

There was an old woman—I tell you true—
Had pains till she didn't know what to do.
She took "sure cure" for them each and all,
But they just grew greater from spring to fall;
Till she prayed for death as the only cure,
And they took her to sail on a lengthy tour.

I'm that old woman—strange is the truth—
But I feel as frisky as in my youth.
I was a captive six months in a heathen land,
Where never a bottle of any brand
Could I procure. Had I staid a year,
I could never have died at all, I fear.
—*Pharmaceutical Era.*

GLASS FOR OPTICAL INSTRUMENTS.

It is stated that an immense improvement has recently been effected in the manufacture of glass for optical instruments by means of the addition to the ordinary materials of phosphorus and chlorine, which in some as yet unexplained way cause the glass to be very much more transparent, and enables it to receive a much higher degree of polish than any optical glass hitherto manufactured. Thus microscopes can be made which will render objects of the diameter of only the one eight-millionth of a millimeter visible, whereas with the best instruments now in use the diameter of the smallest object that can be seen is one sixteen-thousandth of a millimeter. This news, we fear, is too good to be true.—*Sci. Am.*

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society

which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues. Attendance as a delegate at an annual meeting of the Association is not necessary in order to obtain membership. On receipt of the above amount the weekly Journal of the Association will be forwarded regularly.

EXAMINATION OF CANDIDATES FOR MARINE HOSPITAL SERVICE.

A board of Surgeons for the examination of candidates for admission into the Marine Hospital Service will be convened at the United States Marine Hospital, St. Louis, Mo., October 12th, 1891.

Candidates for examination should make application to the Surgeon General, U. S. Marine Hospital Service, Washington D. C., as early as practicable, and should enclose testimonials from at least two reputable citizens, preferably physicians, as to their professional and moral character. No person will be considered eligible for examination whose age is less than 21, or more than 30 years, or who suffers from any physical defect which would be liable to impair his efficiency or incapacitate him from duty. The candidate must be a graduate of a medical college of good standing, as evidence of which his diploma should be submitted to the board.

POPULAR EDUCATION IN HYGIENE.

We understand that the Devonshire County Council, co-operating with the National Health Society, are sending trained teachers and lecturers through Devonshire with a view to extending among the poorer population the knowledge of the means of preventing common ailments, and the selection and preparation of wholesome food. We do not doubt that good will result from this effort to educate the people. It is impossible to over-estimate the mischief which now results from ignorance, but if the ordinary means of prevention of disease and the laws of health can be made general knowledge, a great advance will be made. We shall watch the results of this effort with much interest, and we trust that the attention of other County Councils will be directed to the action of the Devonshire Council. We believe that Mr. Acland, M. P., has been instrumental in initiating this work.—*Lancet.*

LONDON'S SOOT AND FOGS.

The amount of carbonaceous and other particles deposited upon glass houses is a good indication of what the London atmosphere contains, and in many places it is only possible to procure a due admission of light to the plants by frequently washing the glass roofs. At one establishment last week two tanks constructed to collect the rain from a house completed a few years since, were cleared out, and no less than ten barrow-loads of sooty matter were removed, all of which must have been conveyed into the tanks from the glass. One scientific gentleman has been engaged in computing the amount of soot deposited from London air, and arrived at the following conclusions. He collected the smoke deposited on a patch of snow in Canonbury one square link, about 8 inches in extent, and obtained from it two grains of soot. As London covers 110 square miles, this would give us for the whole area 1,000 tons. As the quantity measured fell in 10 days, a month's allowance would need 1,000 horses to cart it off, and these stretches in a line would extend four miles. Hence London's black fog.—*Pharmaceutical Record.*

DR. FERRAN AND HIS "ANTICHOLERAIC" INOCULATIONS.

A delicious instance of the slow grinding of the mills of officialdom has just occurred in Spain. Dr. Jaime Ferrán of Barcelona, whose name was prominently before the world some years ago in connection with "anticholeraic" inoculations, petitioned the Government last summer, when the cholera epidemic was at its height in Spain, for leave to continue his experiments. Whether these "experiments" were to be confined to the scientific seclusion of the laboratory or were to be carried out as before on the public at large, does not appear. In any case, after chewing the cud of official fancy on the matter for nearly a year, the Royal Sanitary Council has only now made up its mind to reject the petition. The *Siglo Medico* points to this as a proof of the how-not-to-do-it spirit which prevails in Spanish administration. It is, however, obviously open to a different interpretation—namely, that the Sanitary Council, from former experience, thinking Dr. Ferrán's inoculations useless, if

not dangerous, but not wishing to appear to place obstacles in the way of scientific progress, judged it prudent quietly to strangle the project with red tape.

WEEKLY COST OF CARE OF THE INSANE IN AMERICAN ASYLUMS.

From the late report of the Committee on Lunacy of Pennsylvania we learn that the per capita weekly expense of maintainance in the principal State Hospitals was (1890) as follows; Harrisburg, $3.81; Danville, $3.31; Norristown, $3.61; Warren, $3.26; Dixmont, $4.31—the average being $3.66. This was for an average aggregate hospital population of 4879. In New York the average cost for 1907 insane in four hospitals was $5.09. In Michigan, three hospitals, 2382 patients, $3.84. In the Government Hospital at Washington, with 1474 inmates, the cost was $4.23. In Wisconsin, the cost was $3.76; in Indiana, $3.96; in Massachusetts, $3.60; in Connecticut, $3.20; in Minnesota, $3.15; in Ohio, $3.39; and in Illinois, $2.95. The great lessening in the cost of maintenance is in some cases due to the self-supporting labor done by the chronic insane. It is strange inhumanity that frequently, and indeed generally, supports thousands of idle people, when their labor rightly and judiciously applied would be a blessing to the one laborer who is supported and to the other outsider who is taxed for the supporting. Let the able ones be put to work.—*News.*

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

To the Subscribers and Readers of the MEDICAL AND SURGICAL REPORTER:

The Mississippi Valley Medical Association will hold its seventeenth annual session at the Pickwick Theatre, Jefferson and Washington Avenues, St. Louis, October 14, 15 and 16th. A full programme of interesting papers has been prepared and provision has been made for the fullest, freest and most complete discussion of the same. Representative men from various sections of the country have been invited to open the discussions. The local profession of St. Louis is a unit to the end that every visiting physician shall be received and welcomed in a regular warm hearted, St. Louis style.

The same qualifications for membership are requisite in this Association as for the American Medical Association, the former being subordinate to the latter. If eligible, you and your friends together with your wives and families are most cordially invited to visit St. Louis and enter into the scientific work and the social pleasures as you may desire.

I. N. LOVE, M. D.,
Chairman, Committee of Arrangements.

TREATMENT OF MORPHINOMANIA.

Two steps in advance have recently been taken in the provision for the treatment, in an institution, for morphine and allied narcomaniacs. One is in England, the other in America. Under the Lunacy Act of 1890 morphine or other inebriates may be received as voluntary boarders into licensed houses for the insane, with the consent of two Commissioners of Lunacy or two justices, by simple application, without specifying the cause for which the applicants desire to be admitted. The American step is the opening of a home at Brooklyn for the reception of 12 *habitués* of morphine, cocaine, or chloral, of whom one-fourth are to be free patients, if an endowment fund of £12,000 can be raised for the latter purpose. The treatment pursued is preliminary sedation by sodium bromide, and rapid reduction of the narcotic, the period of reduction averaging from 10 to 12 days.

PTOMAINES AND BACTERIA IN CANNED MEATS.

Dr. Cassedebat (*Moniteur de L'Hygiéne Publique*) has examined four cans of meat to which his attention was drawn by an outward bulging of the cover, indicating more or less fermentation since sealing. He removed portions of the contents of each tin under strict aseptic precautions and found numerous and various kinds of bacteria. Of the 26 varieties of bacteria found 11 only gave any result when inoculated on animals.

The liquid itself, if inoculated, always caused poisonous symptoms; and just such symptoms as have been observed at times after the use of canned meats.

This fermentation, according to Dr. Cassedebat, can be easily avoided by using a little care in preparing the meat. Still greater care, however, should be used to choose perfectly healthy cattle for killing, and to preserve only fresh meat. If meat, when canned, is infected with bacteria or spores which have not yet acted upon it, no harm will result, for the heat to which the tins are subjected is high enough to render

the bacteria harmless. If, however, ptomaines are formed, the high temperature is of no avail, and the meat remains poisonous. Cassedebat is of the opinion that carelessness and not infected meat is the cause of the trouble in most cases.

TALE OF THE POLYPHILOUS DRUG CLERK.

TOLD IN FIVE TONGUES.

In tempus old a drug clerk lived,
Qui loved pullas deux;
He no pouvait pas quite to say
Which one amabat mieux.

Dit-il lui-meme un beau matin.
"Non possum both avoir,
Sed si address Amanda Ann,
Then Kate and I have war.

Amanda habet argent coin,
Sed Kate has aureas curls;
Et both sunt very agathae.
Et quite formosæ girls."

Enfin the youthful pharmakeus
Philoun the duo maids,
Resolved proponere ad Kate
Devant cet evening's shades.

Procedens then to Kate's domo,
Il trouve Amanda there,
Kai quite forgot his late resolve
Both sunt so goodly fair.

Sed smiling on the new tapis,
Between puellas twain,
Coepit to tell his love a Kate
Dans un poetique strain.

Mais, glancing ever et anon
At fair Amanda's eyes
Illae non possunt dicere
Pro which he meant his sighs.

Each virgo heard the demi-vow,
With cheeks as rouge as wine,
And off'ring each a milk-white hand,
Both whispered "Ich bin dein."

—*Journal of Education.*

CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

SECOND TRIENNLAL SESSION.

We are in receipt of the following letter, which will be of interest to any of our readers who contemplate attending the above named Congress:

1632 K Street,
Washington, D. C., Aug. 18, 1891.

Dear Sir: The following instructions are mailed to you for your guidance in obtaining a reduction in railway fares:

The Trunk Lines, the New York and Boston lines, the Southern Passenger Association, and the Central Traffic Association, will transport persons wishing to attend the Congress from points on their lines to Washington and return at the price of one and one-third the regular fare on the following conditions:

The going ticket must be purchased within three days before the opening date of the meeting.

Each person availing himself of the concession must pay full first-class fare going to the meeting, and must obtain a certificate from the agent of whom the ticket is purchased.

Those holding such certificates, when countersigned by the proper officer at the Congress, can obtain return tickets at one-third the highest limited fare.

Certificates are not transferable, and the return tickets secured upon certificates are not transferable. If any of them are sold or transferred they must be redeemed at the highest first-class rate by the person making such sale or transfer.

No certificates will be countersigned at the Congress except those presented by physicians attending the Congress, or their wives and members of their families; nor will any certificate be countersigned after September 26th.

No refund of fare will be made on account of any person failing to obtain a certificate.

Those who wish to avail themselves of this method of obtaining reduction in fares should present themselves at the office for certificates and tickets at least 30 minutes before departure of trains.

It is absolutely necessary for each passenger before starting to obtain a certificate from the ticket agent of whom the going ticket is purchased, otherwise he can obtain no reduction in the return fare.

There will be no stop-over privileges on the return tickets, which must always be by the same route as the going ticket.

Members may obtain tickets on these conditions for their wives and members of their families, as well as themselves.

Tickets for the return journey will be furnished only provided the properly countersigned certificates are presented to agent at return starting point within three (3) days after the adjournment of the Congress, Sunday not to be counted as a day.

By order of the Committee of Arrangements.

Samuel S. Adams, M. D.,
in charge of R. R. matters.

Clinical Lectures.

THE VALUE OF MODERN WOUND TREATMENT, JUDGED BY THE RESULTS OF LAPAROTOMIES.

BY PROFESSOR E. KUESTER, M. D.,

PROFESSOR OF SURGERY AT THE UNIVERSITY OF BERLIN, GERMANY.

Gentlemen:—We stand to-day under the influence of one of the most powerful discoveries that has ever come within the domain of medicine; a discovery which is destined to largely re-model our science on a new basis. But the experiences with Koch's fluid have as yet been far too limited to admit of any final or definite criticism. While at this opening lecture to you, I feel that it is impossible to let this subject go by unnoticed, yet I will content myself with giving you, at the close of this lecture, the results of a few cases treated with this remedy. In the meantime we will turn our attention to the consideration of another discovery, which in its turn has almost completely re-modelled surgery, and has of late made its potent influence also strongly felt in the field of internal medicine. I refer to the so-called Listerian treatment of wounds.

The key-notes of the modern treatment of wounds are found in the words "antisepsis" and "asepsis." While we for several years past, have spoken of an "antiseptic condition" the term of late seems to have given place to that of "aseptic condition." With what justification this has been done it shall be our task to consider.

Pathogenic germs can infect wounds in two different ways, either through the circulation, or from without. We distinguish, therefore, "self-infection" (the much used word "auto-infection" is a misnomer,) and "infection from without." Regarding the first, as it only can occur under very exceptional conditions, we will not discuss it here.

In infection from without, the pathogenic germs either come from the air, or else they are brought into the wound by the contact of solid or fluid bodies. The views entertained regarding the comparative frequency of these two means of infection have undergone considerable modification. While Lister, basing his views upon the experiments of Pasteur, was of the opinion that the air was the principal means for the carrying of infection, and that, therefore, before this air came in contact with the wound it must be disinfected, these views were opposed on purely practical grounds at first by German surgeons—V. v. Bruns, and others— until finally it was scientifically demonstrated, that no real importance could be attached to the supposed dangers of aëreal infection. Fritsch, of Breslau, was one of the first who disclaimed the necessity of making any provisions in the operating-room against possible aëreal infection, and held such procedures as forcing the onlookers to remove their coats, or to undergo a compulsory washing, as not only unnecessary, but laughably absurd. In the meantime, gentlemen, I hesitate from going so far. Nature has so many ways, and ways which are most difficult to follow, by which she cares for the lives of her most minute offspring, that it surely does not seem justifiable to completely ignore any reasonable proposition or precaution. Can it really be immaterial whether the garments of the students which have possibly come directly from contamination in the dissecting room,—can it be really immaterial, I repeat, whether these germ laden garments are brought into a room where major operations are being performed, or perhaps even large cavities of the body are being opened? Should the often unavoidable crowding of the room, by which mechanically, by the rubbing of garment against garment, the germs are set free and wafted in the air, be looked upon as a procedure entirely devoid of the possibility of causing traumatic infection, so long as the immediate participants in the operation have

taken every personal precaution to free themselves and the patient from infection? Truly, I think not. And, therefore, I still feel constrained to abide by my old rules, and request that the students attending my clinics shall not attend them in the same clothes in which they also visit the institutes of anatomy and pathological anatomy. And further, that in especially dangerous operations, the students present will kindly put on the clean white over-alls which I will provide for their use.

How that may be, however, it is evident that the principal source of traumatic infection, and indeed almost the only source, is actual contact with germ-laden articles. That the skin of the patient should be scrupulously clean, that the operator, his assistants and the attendants should wear no clothes of questionable cleanliness, that the instruments, sponges, hands, and indeed everything which comes in contact with the wound should be absolutely clean or aseptic, is well known, and cannot be too strongly impressed. The greatest danger, without doubt, lies in the nails of the hands; Schede, Kuemmell, Fuerbringer, and others, having demonstrated the fact that numerous pathogenic germs are found both under the nail and around the matrices, and these germs can only too easily lead to an infection of the wound. The trustworthiness of a surgeon nowadays, may be largely determined by the care which he bestows upon the cleanliness of his hands and nails. Especially in major operations too much care cannot possibly be taken. The method which Fürbringer has empirically shown to be of value, deserves imitation, because it at least insures safety to a large, although in no way absolute, degree. It is as follows: The hands and nails should first be mechanically rendered as clean as possible, both by means of a sharp knife (for the nails) and a brush with which the hands and nails are both scrubbed with hot soap and water. Then the hands should be soaked for several minutes in alcohol, and finally immersed in a solution of bichloride of mercury. Mikulicz besides all this, concludes by rubbing iodoform under the nails and around the matrices. With these precautions, it is obvious that the possibilities of traumatic infection are reduced to a minimum.

All instruments and sponges that come in contact with the wound, in fact everything that touches it, must be most carefully cleaned, sterilized, and rendered aseptic. Formerly, we used to disinfect our instruments by immersing them in a solution of carbolic acid, of say 5 per cent., for about an hour before the operation, and from which they were only removed as required. What is far more reliable, is a boiling of the instrument in a weak soda solution. For this purpose we use the apparatus made originally by Lautenschläger of Berlin. The sponges—which by the way, I greatly prefer to tufts of gauze or cotton—are first thoroughly cleaned, and then placed in porcelain jars filled with a 5 per cent. carbolic acid solution. These jars are labelled with the day of the week, so that in choosing a jar, we take one marked with the day the operation is being performed on, and are thus sure of the sponges having at least been soaked for a week in the disinfecting fluid. Also the dressings, sutures, ligatures and even bandages should be prepared with the greatest care. They should be sterilized in an oven by heat, and it is also well to impregnate them afterwards with some antiseptic, such as thymol, iodoform, or others.

A wound treated thus aseptically, a wound which has thus been kept free from every pathogenic germ, must and will take an aseptic course, that is to say, that it must heal by first intention without the formation of one drop of pus. According to this, therefore, asepsis is without doubt the ideal which every surgeon strives for.

This is more true than the ideal theory of antisepsis, held until recently. For, antisepsis as it was originally practiced, offered many difficulties and inconveniences. I may recall to your mind that strict antisepsis, as it was first practiced necessitated a continual irrigation of the wound with an antiseptic solution; that this gave place to an occasional washing of the wound during the course of the operation; this in turn to a douching of the wound just before its closing. But even this mild use of antiseptics is not without danger. None of these germicidal substances are without properties which can be directly injurious to the organism, whether the substance be carbolic acid, or bichloride of mercury, or iodoform, or salicylic acid. In part they occasion regional and general specific symptoms, which may lead to a fatal termination; nearly all exert a harmful action upon the kidneys. This is caused because these substances, after having been absorbed into the circulation, are eliminated through the kidneys, and there cause a peculiar degeneration of the renal epithelium, which when even occurring in a small degree is most harmful to health, and which when severe leads to uræmia and death. To these possible sequellæ must also be added the widely

varying susceptibility found in different subjects, to the action of antiseptics. A moderate dose of iodoform or bichloride of mercury, which in twenty patients could be administered without causing the least unpleasant symptoms, may, in the twenty-first case, give rise to toxic symptoms of extreme gravity. We are, therefore, not in the position to rely without questioning upon the results of the employment of any toxic antiseptic. There is scarcely a surgeon, who, if having used antiseptics extensively, cannot report fatal casualties as resulting from their use.

Theoretically, therefore, there can be no doubt but that the practice of antisepsis should yield to that of asepsis; let us now, therefore, briefly see whether this theory can be supported by practical results.

Even the most careful surgeon is not always in the same quiet harmony with his patient; he is—as is every man—subject to sickness and health, to moods and feelings, which may be, in a certain measure, independent of internal or external influences. Hereby is already occasioned a certain variance of the aseptic attitude. This possible variance is only increased when more than one person comes in contact with the patient. The surgeon is also influenced by the surrounding conditions even possibly more than from his own disposition, and no matter how great his skill, or how careful his method, still, a certain amount of uncertainty will cling to all human actions, and the possibility of mistake, by omission or commission remains open. It is, therefore, a very natural wish, that taking all these possibilities into consideration, the surgeon would desire to correct all possible mistakes by careful disinfection before the closure of the wound.

Herein is expressed the first limitation by which we are confronted in the aseptic treatment of wounds.

A second limitation for this method is found in the fact that we do not always have to deal with wounds inflicted by the surgeon at the time of the operation, but frequently with old wounds, and wounds sustained in every conceivable manner. In such cases an infection of the wound has already occurred, and at present we have no other method at our control than careful disinfection with antiseptics.

A third limitation is found in the fact that we are frequently compelled to operate in such regions of the body where it is impossible to maintain asepsis for any length of time. Wounds of the oral cavity, of the genitalia, and of the intestines, would—in the majority of the cases—not remain aseptic by the mere use of aseptic preparations. In such cases both the dressings and bandages would gradually become infected, and the use of antiseptics cannot be dispensed with.

A fourth limitation is the difficulty in obtaining the necessary material and assistance in general practice and in times of war, on the field of action. Even in a well-ordered clinic, or cleanly kept hospital, it is often difficult to avoid all mistakes, how then is the country practitioner, without the necessary apparatus for sterilization, and without competent assistants, to compete with the results obtained in the well organized clinics? And if this is the case with the average practitioner in times of peace, how is it with the surgeon on the battle-field in times of war? Both must of necessity be satisfied with obtaining the ideal aseptic conditions only so far as it is in their power to do.

If therefore, gentlemen, asepsis is not universally applicable in surgery, then asepsis should not be exclusively taught. In this clinic you will, therefore, be taught both methods, with the hopes that you also may become conversant with the minutiæ of both. It will also be my pleasure to demonstrate to you why at one time I use the one method, and at another time the other; and why, at times, a combination of both asepsis and antisepsis. It is the knowledge of the various remedies, and the ability of being able to pick the ones suitable from them, that makes the successful and skilful physician. There exists no such a thing as "luck" in surgery, in the sense expressed by the great Russian surgeon Pirogoff, but every result of to-day can be based on knowledge and ability.

Let us look about us, therefore, to see and note the results of the application of these fundamental principles, choosing for this purpose a groupe of operations which constitute the most delicate test. I refer to laparotomies.

The first laparotomies were performed at the time when all the profession was agog with wonder over the brilliant successes following the introduction of antiseptics. At that time it was thought impossible to over-do the most stringent application of the method. Von Nussbaum, of Munic, one of the most enthusiastic and worthy introducers of general antisepsis, who only a short time since has been lost to the profession by death, poured his carbolic acid solution by the bucketful into the abdominal cavity, and

ascribed the subsequent collapse, which was only prevented from being fatal by means of artificial respiration continued for hours, not to the action of the drug but to other reasons. At first slowly, but then ever more rapidly the danger of the adoption of such procedures, especially in a cavity of the body, the absorptive power of which could so quickly carry the poison into the general circulation, became realized. But the consideration that the abdominal cavity possessed peculiar anatomical conditions, rendering any infection here much more dangerous than at any other portion of the body, still caused antisepsis to be held in laparotomies longer than in perhaps any other surgical procedure.

We know now that the peritoneum is able to withstand the inroads of several different infectious germs, but only under two conditions; one being that there shall be no large collection of fluid which may serve as a culture medium for the germs, and the other being that in case the germs do propagate with rapidity the displacement of the blood or serum over the entire abdominal cavity by means of peristalsis will prevent the further propagation of the germs in isolated foci.

More important, therefore, than in any other operation is the strictest observance of asepsis in laparotomies necessary. Antiseptic drugs should either not be used at all, or else in the most limited manner possible. The results which Fritsch has obtained with sterilized salt and water solution are absolutely conclusive as to the justifiability of this. In 52 laparotomies he lost only two cases, and neither of these was from sepsis. At the same time, in order to obviate possible errors, or if they occur to render them of as little danger as possible to the patient's life, it is of the highest importance to keep the abdominal cavity dry from all blood or liquids capable of putrefaction or infection.

An important help towards this end is the elevation of the pelvis, recently suggested by Trendelenburg, at least in laparotomies the operative field of which is in or near the small pelvis. This procedure not only gives a much better view of the operative field, but it also occasions a far smaller hæmorrhage than when the patient is laid horizontally. By this elevation the veins of the pelvis are so nearly emptied, that the troublesome parenchymatous bleeding which otherwise frequently occurs, is almost entirely absent.

In the following tables I give the results of a number of laparotomies performed by me at my private clinic, and in the Augusta Hospital in Berlin, during the last one and three-quarter years. In these cases I followed the rules I have endeavored to lay down in this lecture, relating to asepsis, but have also used antiseptics with caution as the case seemed to indicate. The list comprises 60 cases in all.

Exploratory laparotomies, for various causes,—9 cases; 9 recoveries.

Ovariotomies (some of which were most difficult)—18 cases; 18 recoveries.

Salpingectomy, for pyosalpinx,—2 cases; 2 recoveries.

Myomotomy,—6 cases; 2 recoveries; 2 deaths (2 from sepsis, 2 from bichloride of mercury poisoning.)

Vaginal hysterectomy,—3 cases; 2 recoveries; 1 death (from hæmorrhage.)

Echinococcus of the abdomen, (liver, and pelvic mucous membrane),—3 cases; 3 recoveries.

Extirpation of a sarcoma mesocoli,—1 case; 1 death (from sepsis).

Incision of a pancreatic cyst,—1 case; 1 recovery.

Operations on the gall-bladder and gall ducts,—3 cases; 2 recoveries; 1 death (from phthisis pulmonalis).

Laparotomy for ileus (internal strangulation),—3 cases; 2 recoveries; 1 death (from internal strangulation).

Laparotomy for bullet wound of the abdomen,—1 case; 1 death (from sepsis).

Colotomy,—4 cases; 4 recoveries.

Gastrotomy,—1 case; 1 death (from inanition).

Gastro-enterotomy,—5 cases; 1 recovery; 4 deaths from varied causes, but none from sepsis.

Total,—60 cases; 46 recoveries; 14 deaths.

From these fourteen fatal cases let us subtract those which were not attributable to the treatment of the wound: the one gastrotomy, the four gastro-enterotomies, the case of ileus, that of phthisis, and that of hæmorrhage. There remains therefore, 6 fatal cases attributable to the treatment of the wound, and among these, 4 cases of sepsis. One of the latter must also be subtracted from the list, as you will readily admit when you hear the history of the case, which I will detain you by giving briefly.

The patient was a student, twenty-one years of age, who had sustained a bullet wound of the abdomen in a duel. The ball had entered the abdomen to the right of the navel, had passed through the pelvis and could be easily felt through the skin of the buttock, from which it was removed. The

young man was very anæmic and his abdomen was evidently full of blood. Laparotomy was immediately performed and a large quantity of blood found in the abdominal cavity. The intestines were found perforated at four different places, and the mesenterium at four other places. All the openings were sewed up and the abdominal cavity carefully cleaned. The patient died 36 hours after the operation. The autopsy showed a circumscribed septic infection in the region of the ilium, and in its center the cartridge case was found, which must have been torn out of the revolver with the bullet and had passed through the pelvis only stopping when it came in contact with the bony obstruction. This unforseen accident had caused the unfortunate man's death.

Even if we exclude this case there will remain three cases of sepsis and two of bichloride of mercury poisoning. In the two latter cases only a small amount of the drug was used, and that was used with the greatest possible precaution. From the results of these cases I have determined to use no antiseptics in abdominal sections unless absolutely necessary. You will, therefore, see me hereafter perform all typical laparotomies in a purely aseptic manner.

In conclusion I might refer at length to several of the cases given in the table, in which the operation was attended with most excellent results, and which in themselves were of more than ordinary interest. But for lack of time I must reserve this pleasure for some future lecture it having only been my intention in this discourse to clearly point out to you the fundamental principles of our modern method of treating wounds, with a brief glimpse at their results in certain test cases, and upon these principles I propose to work before you. Allow me therefore, to request your participation in my clinical work.

GENERAL PARESIS.

BY JAMES HENDRIE LLOYD, M. D.,

PHYSICIAN TO THE PHILADELPHIA HOSPITAL.

A CLINICAL LECTURE DELIVERED AT THE PHILADELPHIA HOSPITAL.

Gentlemen :—I have taken as the subject for this lecture a few of the more important forms of insanity. I have considered that a large Hospital like Blockley, in a medical center like Philadelphia, and the only Hospital in the city that presents an opportunity for the demonstration to students of mental disease, should not go unutilized. It goes without saying that the subject of diseases of the mind is extremely important to the practitioner of medicine. No apology is required for bringing a subject of such importance before the students who will become the general practitioners, and who in nearly all instances are the first to see the patients in the incipient stages of these diseases. It will fall upon you to recognize the beginning stages of nearly all of these mental diseases and it is of the first importance not only to your reputations as practitioners but also to the welfare of your patients and the community, that you should be able to detect the little flaws which mark the beginning of the often irretrievable ruin of the mind of your patient.

Insanity is not a specialty to be studied only within the walls of an asylum. As a disease of the highest organism in nature it often confronts, and must always claim the interest of the educated physician everywhere.

Among the most important of these diseases is the one which I have selected for consideration to-day. Not only is it one of the most important but it is one of the most interesting of the diseases of the mind. I refer to general paresis. This has many synonyms. It is alluded to as general paresis, dementia paralytica and general paralysis of the insane. These three are the leading designations. General paresis is the term I have chosen as it is probably the one most frequently used. This affection has been well called the scourge of civilized man. We have in all of the lower races and classes of man more or less prevalence of mental disease, but this particular affection seems to be reserved for those who are thrown into the competition and struggle for life in our great civilization. This disease belongs more especially to our manufacturing and commercial centres rather than to the agricultural and rural districts and it is best displayed in the higher types of man. This reminds me to say that we do not find the best examples of general paresis in hospitals for the pauper insane. I could show you much better marked forms in some other hospitals of the city and State, but we must content ourselves with the material that we have. The important fact in the ætiology of the disease is that it is found best developed in highly civilized and developed men,—those who bear the great burdens and take the front rank in the complicated life of our civilization. Hence it is

that we often see the disease best developed in railroad men or professional men. One of the most marked examples that I have seen was in a high official of one of our large railroads. I have seen other examples in lawyers, physicians, actors and politicians; in other words, in men who take upon their shoulders great responsibilities with incessant mental strain.

Having said so much by way of introduction, let me ask what is general paresis? I shall first tell you what it is anatomically, and pathologically, so that as we develop its symptomatology you can, as it were, fit in the symptoms as they arise. General paresis is a wide spread degenerative disease of the cerebro-spinal axis affecting especially the cortical matter of the brain, although not confined to it. In its progress it involves also the cord and even the nerve trunks and the sympathetic system. The degenerative changes involve especially the brain cortex. The disease spreads like a slow fire destroying little by little the important and essential anatomical structures of the brain. This consequently leads to the greatest variety and complexity of symptoms, although these symptoms usually pursue a more or less typical course and admit of a ready diagnosis being made. This degenerative disease of the brain is probably an exhibition of over strain.

We know that the nutritive supply of all organs is under the control of what is termed a vaso-motor system. This system has control of the proper blood supply and nutrition of the parts. In this particular disease we probably have as the initial cause overstrain and loss of the equilibrium of the vaso-motor nervous system. This leads to a flushing of the capillaries and to a too rapid growth and nutritional change. This gradually leads to cell-proliferation, especially in the net-work of tissue which acts as a stroma or scaffolding to support the essential elements of the brain,—the cells and nerve fibres. This overgrowth of tissue leads to a form of sclerosis. This connective tissue overgrowth slowly leads to a blotting out of the nerve elements. Hence the disease has as its essential characteristic, progressiveness. When it once starts it continues and I have yet to see a well authenticated case of cure. It gradually leads to a perversion, and then a destruction, of all the more important functions of the brain and of the cerebro-spinal axis. We can say of general paralysis that a well-marked case, if followed from beginning to end, becomes a walking museum of pathological specimens and a whole hospital ward of clinical neurology. Some one has said there is scarcely any disease of the nervous system that is not more or less displayed by the general paretic before the disease terminates. This is a subject which it is difficult to condense in the limits of an hour, but with the assistance of the patients, who are present, I shall endeavor to give you a statement of the whole process.

One word in regard to your position as practitioners of medicine with reference to this disease. I have said that the general practitioner is the one who first sees the insane patient. There is no case of insanity the recognition of which in the early stage, is more important than that of general paresis. This is, therefore, a very important subject. It is a well recognized fact that of all the insane, the general paretic in the first stage is the one most apt to bring trouble and disgrace upon himself and mortification upon his family. It is, therefore, of importance that we should recognize the prodromal stage of general paresis.

We are accustomed to divide the disease into three stages. The first is the prodromal or incipient stage. The incipient stage is marked especially by a change of character. Beginning in a man in early middle life, for this disease is apt to begin between the ages of thirty-five and forty-five years, an insidious change is observed which often is recognized first by the immediate family and friends of the patient. This change of character is very difficult to describe in words. It is a loss of the acuity of the faculties of the patient. The edge is taken off. It is marked by little lapses of memory, by indifference of the patient to his ordinary avocations; he is no longer the man he was; he no longer has the ability to concentrate his attention, and he becomes rather weak and foolish. He often becomes worse than that; he may become flagrantly wrong in his moral character. This is the period of the disease in which the individual will not infrequently bring scandal upon himself and family by theft or flagrant violations of the moral code. He may be lodged in jail for indecent assault or for stealing in a purposeless manner something that he does not want. At this period he becomes unable to apply himself properly to business. I recall one instance of a prominent business man who was constantly falling asleep in his office. This was the first symptom to attract the attention of those around him. This somnolence is not unusual in the early stages of general paresis. This man would sleep nearly all day in his office-chair and at night he would be sleepless,

disturbing the whole household. During the prodromal stage the individual becomes changed in other respects. He becomes silly and boastful in his manner, and erratic in his business and social relations. He loses his grip on his business and is no longer able to discharge properly his duties. These are the symptoms which are apt to first call attention to the disease.

At this time if a more careful study is made there will be found in addition to the deterioration of mental and moral character, beginning lesions in some of the muscular groups. Recollect that we have a disease which is insidiously working its way through the brain cortex. You have already learned that the muscular system is represented in the brain cortex. That is according to the doctrine of cerebral localization. As the disease advances, attacking here and there a group of nerve cells, it begins to show its effect upon these motor cerebral centres and certain lesions of the muscular system appear. This is marked by ataxia and paresis, which are noted especially in those muscular functions requiring fine adjustment. We note them in the eye, in the muscles of articulation, in the muscles of facial expression and in the muscles of the hand required to execute precise movements as writing, playing the piano, and certain forms of skilled manual labor. At the same time, the muscular change is apt to be seen in the patient's gait. At this time simple ataxia of walking may exist, and also lesions dependent upon some advanced disease of the spinal cord to which I shall refer later. Exaggerated patella reflexes are common.

I now pass to the second stage. This stage is so well marked that it forces itself upon the attention of every one. In this stage we have a more advanced degradation of all the mental and the moral faculties. There is an advance of all the symptoms, but the condition which is most marked is the progressive dementia. Dementia is one of the central symptoms of general paresis. Whatever variations may be seen in other symptoms, this one symptom stands out as a central one, the progressive dementia. In this second stage the patient has advanced from the condition which we call change of character to a condition of decided alienation, or insanity. He is no longer simply a changed man,—he is an insane man. The most marked characteristic of this insanity as put down in the books, although it is not always present, is the peculiar expansive or grandiose delusion. This is a marked peculiarity, the ear mark as it were of the general paretic. This peculiar type of delusion may be misunderstood. The delusion of grandeur of the general paretic is not like any other delusion which we have in the insane. It is marked by an extravagance, a "claim-all" kind of tendency which is not seen in any other form of insanity. The general paretic not only claims that he is rich, but that he is extravagantly and foolishly rich, not only that he is a millionaire, but many times a millionaire. I recall one patient who not only imagined that he was rich beyond all conception of avarice but even that the very blood which fell from a scratch of his finger was pure gold. Another told me that he had money enough to buy the whole world. The individual becomes the founder of cities. He not only founds them but owns them. One patient told me that he owned a city of four million inhabitants in the southern part of New Jersey. These persons think they are very strong in their physical development. They are men of herculean strength. They have immense influence. They can rule the world. They are able to gain any purpose that they want. They have great inventive ability. Any foolish, puerile conception that can occur to the human mind is not too extravagant. This extravagance is characteristic of the delusion of the general paretic. So extravagant is the patient that his friends believe sometimes that he is not sincere; that he is assuming his delusions. These delusions are characterized also by what in technical language we speak of as lack of system and lack of fixation. They are not systematized or fixed delusions. It is important that you should know what is meant by these two terms. Fixed delusion as the words imply is an erroneous belief which is fastened in the mind and does not change. The man clings to a fixed delusion not only from one day to the next but from one week to the next, or from one month to another or perhaps for a life time. I have known a monomaniac to adhere to one delusion for years. This is not characteristic of the general paretic. With him the wealth of to-day becomes something else of to-morrow. You can lead him by suggestion from one delusion to another. They are not fixed in his mind as are the delusions of the monomaniac. Yesterday in looking over the patients in the Hospital, I found a monomaniac who believes that he owns sixty-eight houses. He has clung to this belief for three years. He not only owns them, but he knows who built them. In one sense he is not mistaken, that is, he is not wrong in all his

deductions. He is logical. The general paretic will own sixty-eight houses to-day, to-morrow it may be sixty eight thousand houses and the next day something else. It is an unfixed delusion. These delusions are also unsystematized. An unsystematized delusion is one that is not coherent. It is not persistently and coherently held to. The delusion changes, it is not a systematized belief. The patient does not follow it to its logical conclusions. The monomaniac, who especially has systematized delusions, will act upon his delusion and keep it up for years. He will draw correct conclusions from an insane premise. The general paretic changes his delusions. He puts them on and takes them off, and does not follow them logically to their legitimate conclusions.

In addition to this peculiar form of delusion, coming in the second stage, the general paretic shows also progressive failure in his muscular system. He becomes more and more weakened in his muscular power. I have stated that in the first stage there is some progressive weakness of the eye muscles. This becomes characteristic in the second stage. Certain paralyses of the external and internal eye muscles occur. The pupil fails to re-act to light, and while it fails to re-act to light, it continues to accommodate. This is the Argyle–Robertson pupil. We see this in general paresis, although it is not so frequent as has been held. The pupil in this affection is more commonly an unequal and irregular pupil. You may have a typical case of general paresis and on examination of the eye, you will not find the Argyle–Robertson pupil, but if you look carefully you will probably find unequal pupils. An irregular pupil is also a very characteristic symptom. Instead of a perfectly circular pupil, there will be an approach to the cat's pupil, that is, an oblong pupil, or one pulled down at one point. Be careful that you do not make the mistake of considering this the result of an old attack of iritis. In iritis there is fixation of the pupil with irregularity. It is especially important to make this distinction in specific cases, for specific iritis will give you an approach to this pupil of general paresis. There may be involvement also of other muscles. Some of the recti-muscles may be affected causing strabismus, although this is not common except in the more advanced stages. Ptosis may be present. Beginning disease of the retina or of the optic nerve may be observed. A very common symptom is difficulty of articulation. This it must also be borne in mind is often a symptom of the disease in an early stage. I distinctly recall a young gentleman who came to me several years ago and told me that he had a little difficulty in his speech. He did not know what was the trouble but thought that he needed electricity applied. I did not believe this but in order to gratify him and gain time for observation I made a few applications. On careful examination I found a little ellision of syllables. He did not stammer but here and there he would drop a syllable. This annoyed him. The explanation of this was that some of the centres in the cortex were beginning to be affected. The man was under observation for some weeks until I felt positive of the beginning of the trouble. There was not another symptom except a little suspicious lapse of memory. He could not recall well and could not apply his mind to business. I had the eye ground examined and beginning optic atrophy was reported. I made a diagnosis of a very early stage of general paresis and this was confirmed by the fact that the man developed gradually well marked symptoms of general paresis and in six months was taken to the Pennsylvania Hospital for the insane. He is now well advanced in the third stage of general paresis.

Let me now call attention to the patients before you.

Case I.—I have brought this man before you because he illustrates some of the beginning symptoms, such as lack of innervation of the facial muscles. Looking carefully you will notice a slight alteration in the face. The right side of the face is a little flattened and in addition there is a little muscular spasm. This is usually not so well seen as in this case. Here it is rhythmic and going on constantly. It may not be confined to the face. I have seen these myoclonic, almost rhythmical, shocks in the legs. The tongue is protruded in a straight line. It is an advantage in these cases to have certain test words such as agricultural, parallelopipedon, etc. You will find that the patient has difficulty in enunciating this class of words. He has difficulty in pronouncing some of the labials, linguals and dentals, and where such sounds as R, L, P, D, and T come together he will slide or slur over the words. This man has this difficulty.

Case II.—As the disease advances there is more or less involvement in the spinal cord. There are two diseases especially which are associated with general paralysis of the insane. These are locomotor ataxia and lateral sclerosis. Here is a man whose disease was diagnosed originally as locomotor

ataxia. There is a form of general paralysis which beginning as locomotor ataxia may persist for some years, the patient being free from mental symptoms. As time advances mental symptoms may manifest themselves. This man has all the symptoms of locomotor ataxia. It is in locomotor ataxia especially that the patient has the Argyle–Robertson pupil as seen in this case. He has abolition of the patellar reflexes, fulgurent pains and an ataxic gait. When he stands with his eyes closed, he would instantly fall if not supported. This has persisted as locomotor ataxia for years, but now the man has expansive delusions. He is ready to go and rescue Ireland. He has certain other delusions, and he has a drawling or scanning speech. I think this is a case of general paresis on top of locomotor ataxia.

Case III.—Is an illustration of general paresis in the female. General paresis of a well marked type is extremely rare in the female sex. I have told you that an ætiological factor of importance is great mental responsibility on the one hand, and on the other excesses. These two factors are more prominent in the male than in the female. I do not insinuate that women never take heavy responsibilities on their shoulders, but, as a rule, they do not enter into such active competition as men, and assume the cares that crush down and render necessary the use of abnormal stimulants to keep up the strength. The man who carries upon his shoulders heavy business responsibilities and attempts to keep up his strength on alcohol is the kind of individual who is liable to get general paresis. This is so especially if he indulges in sexual excesses and contracts syphilis. Women are comparatively free from these conditions, heavy business strain alcoholic and sexual excess. This woman, about whom we know very little, has been diagnosed as a case of multiple sclerosis. I believe that she is a case rather of general paresis. She has the peculiar drawling speech seen in general paresis. Multiple sclerosis does not show such distinct mental symptoms as general paresis. This woman has very unequal pupils, the left is very much dilated while the right is normal. When she shuts her eyes you can see the muscular tremor. The pupils do not accommodate or re-act to light. This woman has also lack of attention. She can not keep her eyes on any object. She can not hold her hand out for any length of time. She shows the muscular tremor in the hands and in the muscles of speech. Her mental condition is one of advanced dementia. It is too late in her disease to see the grandiose delusion in its perfection. It may be that she has never had it: it has not been as marked in the few women whom I have seen in this disease as in men.

As this disease advances from one part of the cortex to another we have certain crises. These occur generally in the second stage of the disease. They are, first, epileptic attacks; second, apoplectiform attacks; third, maniacal attacks and fourth, certain bizarre attacks which can usually be called myoclonic attacks. The epileptic attacks of general paresis are very common and characteristic. They sometimes appear at an early period of the disease. In fact the epileptic seizure is occasionally one of the first symptoms observed by family and friends. If a perfectly strong and vigorous man of 35 or 40 falls suddenly in an epileptic attack and, when he revives, you find these slight changes in the eye, and in speech, the lack of attention and lapses of memory, you should be on your guard as to the probable beginning of general paresis. Epilepsy does not begin in middle life without a cause. We have no such thing as essential epilepsy in middle life. It then has an organic basis. You may not be able to determine it, but it is there. General paresis in most cases sooner or later displays these epileptic attacks. These attacks are rather different from those of so called essential epilepsy. In the first place the epileptic seizures of general paresis are apt to be marked by a focal character. While there may be universal convulsive attacks with loss of consciousness we are more apt to have limited attacks, with, or without loss of consciousness. I received a letter recently, from Dr. Brush, of the Pennsylvania Hospital for the Insane, asking me to come and see an epileptic attack in a general paretic. The letter came by mail, and as I supposed that by that time the attack was over, I did not go. I saw the Doctor two days later when he told me that the attack was still going on. The man was in the attack for over two days. These seizures will often continue for hours. They may begin as violent spasms and simmer down to one or two little movements. They may begin as a local spasm and gradually spread from one part to another and ultimately involve consciousness. They may continue for hours in a few muscular groups as myoclonic shocks.

This is a disease of loss of control of the vaso-motor system. This vaso-motor system

is trying to regain control, it is trying to put on the brakes, but it can never quite do it. Of this struggle we have these various clinical expressions in epilepsy and in the congestive and apoplectiform attacks in which the patient falls or lies in coma with stertorous breathing for hours, and which may prove fatal. Again, the patient may have hemiplegia or monoplegia, which if on the right side is associated with aphasia. It looks like a hopeless stroke of paralysis. In the course of two or three days or a week the weakened arm gradually regains power and the patient as it were, comes to a partly normal condition. He is apt to be left the worse, however, for every one of these attacks. Again the general paretic is subject to maniacal attacks. These are of peculiar violence. The patient raves and storms, is incoherent and has little objective consciousness. He is unable to appreciate anything about him, and is quite violent and often filthy. Great motor restlessness, rather than mental agitation, sometimes marks these attacks. The man, however, is not dangerous. The mind has lost so much of its integral part that it is unable to concentrate on a definite purpose. The patient is not suicidal or homicidal. He sometimes threatens suicide, but it is a spurious tendency to suicide. He has not concentration or power enough even to kill himself. These are important points to remember. He may, however, do a great deal of damage to property and may do injury to himself inadvertently.

We now pass to the last stage of this disease. In this stage the patient having tended constantly downwards, we have him at last, leading a purely vegetating life. Memory, mind, judgment, consciousness, ability to move the muscles properly, gone, the ability to swallow, everything gone from him, leaving him merely a vegetating mass of humanity. In this last stage, he becomes the victim of trophic disorders. Bad bed sores may form. These are difficult to manage and often contribute directly to the patient's death.

Case IV.—This man is in an advanced stage of the disease, and exhibits complete dementia. The pupils are unequal. It is almost impossible to understand him when he speaks. There is great muscular debility. He is unable to converse, to feed himself or to make known his wants. The clinical history of his case is too long to be read at present. It suffices to say that he has passed through the stages of expansive delusions, muscular and speech defects, and an occasional maniacal crisis. The patient is almost bed-ridden, and will be entirely so in a few weeks, if he survives that long.

Another characteristic of general paresis is the occurrence of remissions. Often where the disease has lasted for some time the patient will suddenly become much better, so much better that he is taken from the asylum and perhaps returns to business. His fond relatives are confident that the doctors have taken an extremely unfavorable view of his case or made a mistake in diagnosis. The patient, to their eyes, becomes practically a well man. He may have a little of the pupillary defect left, some fine tremor of the facial muscles and a little lapse of his speech, but his mental condition is improved and his friends feel that a mistake has been made. If you put such a man back to business and subject him to the strain of overwork, or even if you do nothing with him but permit him to lead a quiet easy life, he will sooner or later inevitably relapse. I never knew an exception. This phenomenon of the disease is of importance from a medico-legal point of view. Several years ago this whole community was much exercised over this very subject in the case of the sheriff of the city. He had become a well marked case of general paresis. I saw him frequently and signed his certificate, and testified before the commission which deposed him from office. The Sheriff is a very important officer, as he gives title to property amounting to many thousands of dollars a year, and draws the jurors for the criminal and civil courts. The physicians were asked by the commission whether if a remission should occur the individual would be able to execute the functions of his office. I necessarily answered "no." There was nothing to make us regard the man as even approximately recovered, while every symptom indicated that if he attempted to bear the burden of office, he would inevitably relapse. He did relapse and died in the course of a year.

Another medico-legal point arises in cases of theft and the breaking of certain moral and civil laws. It is important that in such cases the disease should be recognized in its early stage. Such individuals without any real motive and in a purposeless way which is difficult to describe, will steal objects which they do not require. The patient simply takes the article from the counter, slips it into his pocket, perhaps shows it to some one on the street, and the next day does not know where he obtained it, or what has become of it. Such persons have been

sent to jail, I believe, although not within my observation. Sexual crimes are much more common—or, at least, attempts at sexual crimes. One patient in this city made improper advances and indecent proposals to young school girls on the street at the noon hour. Of course great scandal and mortification may arise from this very common tendency in the general paretic.

COMMUNICATIONS.

ON THE CARE OF EYES DURING INFANCY AND CHILDHOOD.

BY J. WALTER PARK, M.. D.,

LATE CLINICAL ASSISTANT ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS, LONDON, ENG.—OPHTHALMIC SURGEON TO THE HARRISBURG HOSPITAL, AND CHILDRENS' INDUSTRIAL HOME, HARRISBURG, PA.

The care of eyes during infancy and childhood is a subject of very great importance, and one which in the majority of medical journals has not received the attention by ophthalmologists that it should have received. There is at present considerable written upon a great many ophthalmological topics, but genarally most of them are written for journals devoted entirely to eye work, and it is very seldom that the general practitioner subscribes to journals which are intended for specialists, and the result is that he is, as a rule, not well posted upon the latest and best line of treatment in ordinary diseases of the eyes with which he comes in contact, in his general practice. For this reason I have taken the liberty of addressing a few words of advice to the general practitioner which if observed and carried out will, I hope, repay the time and labor spent in so doing. Blindness among children is becoming so prevalent that National legislation for its prevention is being urged as a necessity by a great many Medical Societies throughout the world.

Sanitary and antiseptic measures are as essential to the scientific treatment of diseases of the eyes, as antiseptics are to the successful practice of surgery. The physician who now neglects asepsis as well as antiseptics, in the treatment of diseases of the eyes, will undoubtedly be held accountable by the laity in general as well as by the profession at large, for all cases of blindness resulting from such wilful neglect of these precautionary measures. Ignorance on the part of the attending physician or nurse in the present age of advancement will not excuse them anymore. Infancy and childhood suggests a division into two periods. 1st, the period of infancy, 2d, the period of childhood. An infant is considered as such from the time it is born until it begins to walk, which is from one to two years. The first two weeks of an infant's life are the most important of its entire existence, and require the most careful attention upon the part of the physician and nurse; more so than at any other time of its life. I have reference to the lying-in period. It is a common occurrence for a mother to bring her child to my office, accompanied by a letter from her family physician, for a consultation as regards her child's eyes, which, she says, have been nearly or entirely blind since her confinement, when, she says, the child had very sore eyes from a cold it caught about that time, when the sole cause was that much dreaded disease, ophthalmia neonatorum.

The prophylactic measures which give the best results during the "lying-in time" and which should be followed out by the physician or nurse, are as follows: Immediately after the birth of the child carefully cleanse its eyes with absorbent cotton, carefully removing all secretions from them, then again with cotton saturated with 1–10,000 bichloride solution, or weak boracic acid lotion. After handing the child to the nurse, (which should be a trained one, or the physician should do it himself) to be washed, she should first wash its eyes (without the use of soap) with a pipette, by carefully separating the eyelids, and in like manner with either of the above antiseptic lotions. This is done for a double purpose; first, to prevent any catarrhal condition of the eyes which so often arises from a lack of these precautionary measures. Secondly, to prevent ophthalmia neonatorum, the disease which produces so much blindness among children, and yet when the proper precautionary measures are taken, the percentage of cases is small, and the results good, comparatively speaking. Should a case occur, however, of all the various methods of treatment which I have employed, that of Prof. Meyer, of Paris, has been the most efficient. This mode of treatment is as follows: I take a tiny stick (a burnt match end answers very well) with some absorbent cotton wrapped around the one end of it and saturated with a 1–3.000 bichloride of mercury solution combined with a weak boracic acid lotion, make a

thorough sweep in under both lids, being careful to extend well up in under the upper lid, and in like manner in under the lower one. This should be done for about three successive days, after which the profuse discharge generally ceases and it should then be treated as an ordinary case of conjunctivitis, with argentum nit, and boracic acid lotions. The majority of cases if treated in this manner will get well in from one to two weeks. The time and good results gained by this method of treatment is accomplished by the entire wiping away and destruction by antisepsis of all the micrococci (which is the accepted theory of ophthalmia neonatorum, it being the same as in gonorrhœa,) in about three applications, which is not accomplished so quickly by any other method to my knowledge. I wish to lay particular stress upon going well up in under the lid when making the applications with the cotton on the stick. Frequently some hæmorrhage will follow these applications, but not sufficient to interfere with the good results obtained, or to warrant a discontinuance of the same. I have never had a case more than two weeks until it was discharged well, and most of the time only eight to ten days.

After the "lying-in" period and the child comes under the sole charge of the mother, a few words as regards protecting its eyes from bright lights, etc., will not be amiss at this juncture. When it is taken out for a carriage drive, never have it face a bright sun or electric light for any length of time without having its eyes protected. Dr. David Little, of Manchester, Eng., cites a case of retinitis, and also one of blepharopasia, due to these causes. Snell, of Sheffield, speaks of a case of partial blindness resulting from the reflection of the sun upon the eyes by a reflector while passing along the street. Swanzy, of Dublin also mentions a case of central amblyopia in a gentleman due to a long carriage ride facing the sun, without any protection to his eyes. Never have a child lying in its cradle, or crib, facing a bright light when it can otherwise be avoided, and likewise protect them from draughts of cold air, dust, etc. When giving a child its bath, do not use any soap in washing its eyes. Use clean tepid water, rubbing gently over the eyeball so as not to produce any pressure, and thus prevent an accident which has occurred occasionally viz., dislocation of the lens. Work of that kind should only be entrusted to a good nurse when the mother cannot do it herself. Ptosis or dropping of the eyelids is sometimes noticed in children and is generally due to some irritation of the nervous centres, which by receiving proper treatment, restores the lids to their natural positions. A permanent paralytic condition requires operative measures to remedy the defect. Among the more frequent inflammatory diseases of the eyes of children is catarrhal conjunctivitis, and should be treated with the ordinary boracic lotions, thorough antisepsis, and soothing emolients to the edges of the lids to prevent them from adhering during the night, and prevent incrudations.

A habit which is still in vogue among mid-wives and some practitioners, is that of ordering the child's eyes to be washed frequently with the "mother's milk"; it is useless to say that such modes of treatment are now only practiced by charlatans, and should be discarded. Another frequent and very troublesome disease of children is phlyctænular keratitis and conjunctivitis, and is readily recognized by the small phlyctens occurring in multiple numbers, and mostly at the margin of the cornea in the conjunctiva, and sometimes on the cornea as well. Boracic lotions, and an ointment of atropine and yellow oxide of mercury applied to edge of lids, and a small quantity in the eyes will soon cure these cases. Its frequency of recurrence necessitates the treatment to be kept up for some time after the child seems apparently well.

The exanthematous fevers are all prone to cause the various ophthalmias, especially measles, also scarlet fever, variola, etc. The hygienic surroundings of all patients having any of these fevers should be of the best. Thorough cleanliness in every respect should be a daily command by the attending nurses. As soon as any form of ophthalmia appears, treat it at once. Antiseptic bathing of the eyes every few hours, cooling lotions, shielding them from bright lights, carefully removing all crusts from lids and applying soothing ointments is advised in all such cases. Any strumous condition of children should always have prompt medical attention, so as to prevent these various forms of ophthalmias which are so apt to prevail among that class. The over crowding of children in tenement houses in the various sections of cities, with a lack of sanitary precautionary measures are also prolific causes of these infectious diseases. One of the most horrible and contagious diseases due to the same cause is, trachoma, or granular conjunctivitis. Too much emphasis cannot be put upon the proper hygienic management of such patients, for by the intelligent

management of all such cases we can generally prevent a spreading of the disease when it first makes its appearance. When a case of trachoma occurs in a family of children the patient should at once be isolated from the rest. This is very often neglected, especially in Homes for Orphan Children, and the result is an epidemic of this intractable disease. It is also quite frequently found in public schools, and unfortunately they are allowed very often, to keep on attending school, intermingling among the rest of the scholars, using the same towels, etc., which of course should be strictly forbidden.

After isolation, treatment should be begun at once. All the aseptic and antiseptic treatments previously mentioned are applicable in these cases. The exclusive use of their own wash basins, towels, etc., should be strictly adhered to. Antiseptic soaps, such as "Stiefels," and others similar in composition, are excellent to wash their hands and eyelids with. Children should not be allowed to return to school until a responsible oculist certifies that they are entirely well. Never entrust the care of children to a "nurse girl" who has any form of ophthalmia, until you are certain it is no contagious disease. The medical treatment of trachoma or granular conjunctivitis is so varied in the different stages and forms of the disease, that to discuss an outline of treatment would be exhaustive and superfluous in a paper of this kind; but I will here remark, however, that they should always be under the care of a skilled oculist, or one thoroughly versed in the treatment of such cases. Much time and suffering can be saved when properly treated in the initial states. Spring catarrh, or what is more generally known as "Pink eye," is also a contagious disease and is under the same strict hygienic injunctions as all the rest of the contagious ophthalmias. If no precautionary measures are taken it soon becomes epidemic and is generally a very intractable disease to treat, unless taken in its very earliest stages. It generally yields nicely to the usual boracic and bichloride lotions; sometimes, however, it requires applications of 1 per cent. solutions of argentum nit. in addition to the above lotions. The next most important time of a child's life in regard to its eyes, are its school days. According to a very eminent authority on nervous diseases "no child should be sent to school before it is eight years of age," for various physical, as well as ophthalmological reasons. The ophthalmological reasons are, that a child's eyes are not fully developed yet, nor do the several coats of the eye have the same amount of elasticity to resist the severe strain put upon them in the constant convergence as they have at the age of 8 to 10 years. It is a mistake in parents who desire to have their children mentally developed at the age of 8 years, that they should have at the age of twelve. The further advanced a child is in its studies, the more its parents are pleased never thinking that this advancement is always incurred at the expense of a great deal of muscular strain upon the ciliary and recti-muscles which always has a deleterious effect upon the ocular coats when the eyes are excessively used, and especially so, at an early age. Myopia and all its consequences, as well as all the symptoms concomitant with eye strain, such as, headaches, dimness of vision for distant and near objects, blurring of type, epiphora, blepharospasm, blepharitis and conjunctivitis may all be brought on by too early, and excessive use of the eyes, and which can generally be prevented by the proper precautionary measures, in that direction. The majority of children are slightly hypermetropic when born, but very frequently become myopic after some years of close application to their studies. A studious child may by continuous, and excessive use of its eyes bring on myopia, notwithstanding that it is hyperopic to the extent of about one dioptre. This is brought about by the continued convergence required at near work, by which an undue amount of tension is produced upon the sides of the eye-balls, and thus causing their elongation in their antero-posterior diameters which is always the case in myopic eyes. Half day sessions of school of 3 hours each, is sufficient time for children to use their eyes at their studies until they are ten years of age. While at school or at home they should always be taught to hold their books as far off as possible, consistent with good vision. Alternating, periodic and constant strabismus is generally due to hypermetropia, which if corrected by proper lenses will effect a cure, and prevent a permanent strabismus, which generally is the result. If it remains uncorrected it will then require operative treatment. If a high degree of hypermetropia exists, and a squint of 20 to 30 degrees, you should correct all of the hypermetropia under full mydriasis, and after having it corrected for 3 or 4 years, and there still remains a strabismus of ten degrees or more, you may be obliged to perform a tenotomy or advancement of one of the recti-muscles. This should be done for

two reasons: First, to save the eye from becoming amblyopic, and second, for the aid it renders the other eye in bin-ocular vision, as well as cosmetic appearances. I have known a case of squint of 20 degrees convergence entirely cured by a continuous course of atropinigation of both eyes, and all refractive errors fully corrected. There are a very great many cases of strabismus of 15 to 20 degrees convergence operated upon for the mere sake of having it said that they operated on such a case, and in the majority of them the result is worse than if left alone. All such cases should first have a thorough trial of correcting lenses, when we know the defect is due to refractive errors.

As soon as a child complains of headaches, blurring of type, epiphora, dimness of vision for near as well as distant objects, and a congested condition of the eyes, it should immediately be stopped from all near work, and be examined by some responsible oculist and have such treatment as he may direct. Traumatic injuries to the eyes are of frequent occurrence, and none more dangerous than the ones produced by playing the game so much indulged in by children, and generally known as "Catty," or "Knip." It should be prohibited by law, as many an eye is destroyed by a "Catty" or "Knip." Hæmorrhages into any part of the eye, especially those occurring in the anterior chamber, vitreous, and retinæ, should have prompt attention. They are frequently produced by blows from sticks, a slap of the hand over the face and eyes, throwing of balls, falls, and sometimes by school teachers throwing rules, &c. at children in the school room. They usually absorb, and comparatively good results are obtained by leeches, purgatives and alterative treatment. Should a hæmor, rhage occur in the muscular region, blindness generally is the result. Much more might be said upon this subject by taking it up more in detail, but to the general and busy practitioner a general review of the more important points are sufficient, and I trust may be of some value to all who may take the time to read them.

SWEDISH MOVEMENT CURE. *

BY DR. HENRIC SPARRE,

MILWAUKEE, WIS.

There cannot be anything of greater importance than the human system for the maintainance of good health, than normal blood circulation and rich blood.

To understand that it is impossible to control these, we must investigate the forces that accomplish it.

We will divide that which takes place in the human body into Cause and Effect. The nerve centers furnish the motive power, and their ability to continue with this depends upon their receiving nutriment from the blood in equal proportions of expenditure. The remaining portions are a combination of effects, brought about in an absolutely mechanical manner.

Some of these nerve forces are, as we know, controlled by our will, others are perpetual through life. Notwithstanding, both are subject to that mentioned above. None are able to continue furnishing necessary motive power without receiving their normal share of nutriment from the blood, and carrying off the used up parts through their proper channels. The venous blood absorbs and carries off the waste, and the arterial blood (through blood corpuscles) furnishes the material for new formation. This is done mechanically. You will readily perceive that if we control the circulation and undertake contractions and expansions of muscles, we also control nutrition and absorption. The heart is the organ that keeps the blood circulating, aided by the activity of the greatest part of the human body. Nature has wisely arranged that through the activity, the nutriment and absorption are materially increased. Absorption is a mechanical consequence of the speed of the venous circulation and in direct proportion to it. Diminished speed, diminished absorption, viz., congestion.

By mechanically forcing the blood in the main vessels, which, as tributaries, take up those where the congestion exists, and preventing its return, if the vessel is not provided with valves, will force its filling from below, and as a natural consequence, cause the blood in the congested tributaries to move faster.

Absorption normally restored and maintained, it can only be a matter of short duration until consequences of congestion are entirely removed.

There cannot be congestion in one place without causing checked arterial circulation. The restored circulation in the congested veins will admit the arterial blood. To illustrate, by swinging the feet actively circulation is increased, but the power required in performing it will soon cause exhaustion, which proves that an immense amount of nerve force is expended. If the person re-

* Read before the Milwaukee Medical Society, June 23, 1891.

clines and another scientifically twists the feet, better results will be obtained without any expenditure of nerve force. This is the principle of my profession in treating nervous and functional debility.

The importance of normal circulation for producing the blood is evident, and there is only one important feature of the process upon which the circulation has less influence, viz., assimilation. And there is not one that we can control as thoroughly by scientific manipulations, bringing the epithel in contact with the contents of the intestines, materially increasing the amount of chyle obtained. The functions of the spleen, whatever they are, and the usefulness of the pancreas and liver will unquestionably be aided by normal circulation of blood through them.

We have now come to another process of the utmost importance for the system, the discharging of refuse.

We can aid materially the action of the lungs, and in increasing that portion of the capillary circulation that brings the blood in connection with the pores, the exhalation is materially improved.

We can aid the kidneys by preventing congestion, or removing it if it has taken place, and in restoring circulation to the bowels. We can produce passage if the forces that induce the peristaltic motions are nearly or entirely exhausted, and with continued aid, the exhausted parts will have time to recuperate.

If there are local disorders in the circulation, they can be restored by applying former principles.

The diagnosis reveals the aid required to remove the cause of the disorder. The effect of movements and manipulations tells the experienced practitioner with what combination of movements, or manipulations that effect will be produced. As rarely anything can be done in aiding nature that has not more than one effect, some of which may be detrimental, counteracting manipulations must immediately follow to neutralize them, without interfering with the others.

The general impression of the medical profession seems to be that my treatment is good only for muscular development. We certainly can develop muscles, but does not this indicate that we can increase nutrition and absorption? In fact, we use the muscles to aid us in controlling the blood circulation in other parts. By undertaking the functions of the controlling muscle or muscles, we can reduce the effect of contraction and expansion to only one muscle or set of muscles and thereby regulate the circulation in the vessels within and through them, their branches and tributaries.

There are positive requirements to enable intelligent treatment of human ailments. Thorough knowledge of anatomy, physiology, the nature of the disorder and cause of the disturbance; and in my profession also the distinct effect of manipulations in every condition.

The English name "Swedish Movements" is misleading. There do not exist decided schemes of movements for treating diseases. Every case demands individual treatment. To illustrate, I mention the fact that in the Central Institution in Stockholm where the record is kept of movements used, the number from 1834 to 1885 exceeds 16,000, and few weeks elapse when cases do not come to me for treatment that call for movements I have not seen nor thought of before.

It is essential to closely watch the effect of treatment, to discover if desired effects result, as it verifies or disproves the diagnosis; and as different stages require change of treatment. I can refer to one case which required 42 schemes of treatment before the cure was effected.

Massage or "to rub" is simply four ways of rubbing, very efficient to aid in removing swellings of the joints, and increase capillary circulation on the surface, if scientifically performed.

A CASE OF COLOTOMY.

BY BENJ. W. WHITE, M. D.,
BRIDGEPORT, CONN.

In this short description of a case of colotomy, I shall not attempt to describe the various operations and their methods of performance, or detail the circumstances under which such a procedure might seem justifiable. But will only refer to a few points which may serve as a subject for your discussion of the merits of this operation.

CASE I.—The patient, a female, aged 53, married, but who had never borne children consulted me February 8, 1891, with reference to a growth in her abdomen. Her health had not been good for five years; having suffered more or less from constipation, dyspepsia and headaches, but had not noticed the abdominal growth until a few days prior to my seeing her. At the request of the patient, Dr. Lauder was called in consultation, and we established the diagnosis

of carcinoma involving the uterus, rectum, posterior wall of the bladder, vagina, and broad ligaments. The patient's condition rapidly grew worse until March 1, when marked stenosis of the rectum occurred, and the passage of fæces was only accomplished by partial dilation. At this stage colotomy was proposed and declined, and I was obliged to employ the best means I could to control persistent and severe vomiting. The use of the various drugs and hypodermic syringe did not achieve much in our favor. Meanwhile the rectal occlusion was becoming more complete, and on the 14th instant closed the passage, and nothing escaped from the bowels until the intestine was incised one week later (March 21st). At this time the patient's condition was not very favorable for operation; but with her consent and the valuable assistance of Drs. Young and Cowell I opened the intestine in the left inguinal region after the method of Littre. It was my intention to stitch the gut to the margin of the wound and leave it until the next day before opening it, but adhesions were so numerous and dense that while endeavoring to lift the loop of intestine up into the wound that portion which was grasped with the forceps was felt to give way and had to be closed with a clamp which was fastened and left in the wound until the next day, when it was removed and a good opening which allowed the passage of gas and fæces, was established. The patient rallied very well from her state of shock and lived twenty three days after the operation. During these twenty-three days her bowels moved daily, the nausea and vomiting lessened, the distress caused by flatus disappeared, and her temperature remained below a hundred degrees.

My reasons for operating in this case were:

1. To give the patient an opening through which to get rid of her intestinal contents.

2. To relieve vomiting and abdominal distension, and to make life more bearable while she did exist.

The cause of death in this case was exhaustion from lack of nutrition.

ACUTE DISEASES OF THE MIDDLE EAR.[1]

BY H. M. DUNLAP, M. D.

BATTLE CREEK, MICH.

Mr. Chairman and Gentlemen of the Section; I feel somewhat out of place in presenting this subject before you who are mostly older than myself both in experience and in years; however, the importance of the subject, together with the fact that it receives so little attention, not only from the general practitioner but from most specialists as well, justifies me, I think, in calling your attention to it on this occasion.

I am not here to present any new ideas or methods of treatment, nor yet to give my own experience in this branch of medicine. My only object is to stimulate a deeper interest in this branch of the healing art. There is no line of work in medicine which is so much neglected or little understood by the general practitioner as diseases of the ear, and I dare say there are comparatively few who have a thorough knowledge of even the anatomy of this organ.

There is no cause that needs apostles more than otology. We have gynæcologists by the score, we have surgeons and ophthalmologists, all of whom are working nobly for the benefit of suffering humanity. But where are the aurists? It is true that most of us print our cards with "Oculist and Aurist," but how many of us give half the time and attention to the ear that we do to the eyes?

It may be urged that the treatment of diseases of the eye give satisfactory and even brilliant results; that the cases of ear affection who come to us are chronic and yield very unsatisfactory results to treatment. All this, I admit to be true in a majority of cases, and it is this fact that urges upon us the duty of educating, not only the profession, but also the laymen in the importance of attending to the acute diseases of the ear and thus prevent a great many of the chronic ones to say nothing of the suffering that may be alleviated.
